Dr. Denis Coffey, President of the Irish Free State Medical Council, in a published statement mentioned that the Medical Register for the Irish Free State will come into operation on May 26th next. This matter was referred to in the *Journal* of April 7th (p. 605). All medical practitioners at present entered on the *Medical Register* of the General Medical Council and resident in the Free State will automatically be entered on the new Register without fee. Practitioners whose names are entered on the general *Medical Register*, but who are resident outside the Free State, will be eligible for registration without fee in the Free State Register, provided they make application within one month of the date of the establishment of the Register—that is, between April 26th and May 26th. The agreement included in the schedule to the Act provided that every medical practitioner practising in the Free State must be on the Free State Register, and cannot legally practise unless so registered. The agreement also

provided that the powers of the General Medical Council will continue as before, subject to the law of local registration for practitioners living in the Free State. The General Medical Council, said Dr. Coffey, remains, and people when they are qualified can register with the General Medical Council, but if they wish to practise in the Free State they must have their names entered on the Free State Register, even though they are entered on the general Medical Register. Dr. Coffey expressed the opinion that it would be wise for all young medical practitioners qualifying in Southern Ireland after the establishment of the Free State Register to have their names entered on both registers—the general Medical Register and the Free State Register. He added that the Free State Medical Council had now completed most of its preparatory work, and it is understood that the first Free State Medical Register is likely to be published soon after January 1st, 1929, and reissued thereafter every year. Applications for registration should be sent to the Medical Registration Council, Room 123, Customs House, Dublin.

#### Food Preservatives in the Free State.

The draft regulations regarding the use of preservatives in food issued by the Irish Free State Minister for Local Government and Public Health under his statutory powers make the sanitary authority and officers of local authorities responsible for the enforcement of the regulations. A person who exposes or offers for sale by retail any article which contains any preservative must label the article or exhibit a notice in a conspicuous place, so as to be easily readable by the customer. No person may sell cream which contains any thickening substance, and no person may sell any article for use as a preservative of, or colouring matter for, any article of food if such use would be contrary to the regulations. Any officer authorized by the Minister and any officer of the sanitary authority acting in the execution of these regulations is empowered to enter premises where articles to which these regulations apply are prepared, packed, labelled, or stored. He may take samples, and, if so required, make reasonable payment. If an article is sold within the district of the authority contrary to the regulations, the authority or officer can, in addition to taking proceedings against the seller, take proceedings against any previous seller of the article, and the sale by the previous seller will be deemed to have taken place within the district of the authority. Subject to any directions given by the Revenue Commissioners, after consultation with the Minister, the customs and excise officers will have power to take samples of consignments of imported articles to which these regulations apply, and to send them to the State chemist for analysis. The certificate of the State chemist or the public analyst of the result of the chemical examination of a sample will be sufficient evidence, unless the defendant requires that the person who made the examination be called as a witness. These regulations will not apply to any article intended to be exported or re-exported, or for use as ship's stores.

## England and Wales.

#### The National League for Health and Maternity.

THE report of the National League for Health, Maternity, and Child Welfare for 1927 gives ample evidence of the wide range of useful activities carried on by the seven national societies federated under this title for co-ordination and mutual assistance, each retaining its autonomy. The league arranged in 1927 a series of lectures to various organizations of women and girls, circulated a film on physical education, sold no fewer than 360,000 copies of its publications, administered the Tired Mothers' Holiday Fund, and controlled and financed three convalescent homes for infants and young children. On the educational side the National Association for the Prevention of Infant Mortality continued the important task of providing, by means of lecture courses, advanced and

elementary instruction for health visitors, nurses, midwives, and others, and arranged two series of lectures on the hygiene of married life intended for educated parents. In addition, efforts were made by research, discussion, and propaganda to advance the objects of the association. The report of the Association of Infant Welfare and Maternity Centres expresses regret at the slow growth in 1927, this being due largely to the failure of centres under municipal control to secure affiliation. Nevertheless, satisfactory progress is being made in the work of the 1,200 centres already linked with the association. The report states that centres are now frequented alike by the working classes, though not by the poorest, by the artisan class, and by various grades of middle-class mothers, but that there is a growing desire among the comparatively well-to-do mothers for centres of their own, supported entirely by payment. One such centre has been established in Chelsea, and another is being organized in a rural district. The work of the league has been hampered by financial difficulties, and although some benefit is gained from the considerable profit on the sale of publications, further assistance is needed to ensure more adequate provision for the programme which is contemplated.

#### Central Midwives Board.

At a meeting of the Central Midwives Board for England and Wales on April 4th Sir Francis Champneys was re-elected chairman, and it was announced that Mr. Victor Bonney and Dr. Vincent Dickinson had been re-elected to the Board by the Royal College of Surgeons and the Society of Apothecaries respectively. In reply to a letter from the Ministry of Health it was decided to inform the Minister that the Board is in agreement with him as to the desirability of an inquiry into the training of midwives and the conditions under which they are practising, and that two members of the Board will be willing to serve upon any committee which he may appoint in this connexion. The Board hopes that the Minister will, at the same time, bear in mind the importance of mobilizing all the best available forces in investigating the problem of maternal mortality. A letter was read from the Ministry enclosing a copy of one from the General Medical Council, and requesting the Board's observations on the resolution adopted by the Executive Committee of the Council regarding the memorandum on administration of drugs by midwives. Reference to this resolution was made in the *Supplement* of March 31st (p. 109). It was agreed that a reply, as drafted by the chairman and approved by the Board, be sent to the Minister. In response to letters from the medical officers of health for Gloucestershire and Liverpool the following resolutions were adopted:

That in the Board's opinion a midwife has, like a doctor, the right to refuse to book a case which she does not desire to attend, and that this right would be properly exercised when the midwife has reason to believe that the patient will refuse to permit the necessary examinations to be made or to carry out the midwife's proper instructions. The Board's opinion, of course, does not extend to cases where attendance may be demanded on humanitarian grounds, or in respect of which the midwife, as regards attendance, owes a duty to some other body, person, or authority responsible for the provision of an adequate midwifery service. The midwife is quite at liberty to consult the local supervising authority in any doubt. Under these circumstances the Board sees no necessity to consult with the Ministry of Health with regard to the opinion in question.

With regard to the definition of "abortion," if the Board finds that the present definition is misunderstood, it will reconsider it at the next revision of the rules.

The following resolutions were adopted in reply to a communication from the honorary secretary of the Council of British Ophthalmologists:

1. That in the existing rules of the Board it is stated that it is desirable that, whenever possible, arrangements should be made for pupil midwives to visit ophthalmic hospitals or the ophthalmic departments of general hospitals for the purpose of gaining direct experience of ophthalmia neonatorum.

2. That as soon as sufficient centres for the treatment of ophthalmia neonatorum are established, the Board will take into consideration the question of making the attendance of pupil midwives at such centres compulsory.

3. That as regards the "recognition" of ophthalmia neonatorum, the Board does not expect midwives to diagnose disease of any kind, but to observe and report "any abnormality" (Rule E 20). In the case of affections of the eyes, it requires the

midwife to summon medical help in all cases of "inflammation of or discharge from the eyes, however slight" (Rule E 21 (5)).

It was agreed that the following note be added to Rule E 21, and that the Minister of Health be asked to approve the addition:

"The foregoing lists are not exhaustive and do not include all cases in which medical help should be summoned."

According to Rule E 20, "any abnormality" requires medical help. The instances in Rule E 21 refer to some of the most striking and important abnormalities.

#### Lunacy Returns for London.

The total number of insane persons for whose accommodation the London County Council was responsible on January 1st last, according to a return presented to the Council, was 20,147, an increase of 340 during the year. Of this number, 19,715 were accommodated in the London county mental hospitals, and all but 1,400 of the total number provided for were rate-aided cases. In addition to these patients, for whom the London County Council is directly responsible, there were 132 insane persons resident in Poor Law guardians' institutions in London, 104 boarded out by the guardians among relatives and friends, and 4,640 harmless chronic patients accommodated in the Metropolitan Asylums Board's institutions. The number in this last category, which excludes cases dealt with under the Mental Deficiency Acts, is the lowest recorded since 1890. The total number of insane persons chargeable to parishes and unions in the county of London and to the county itself at the beginning of the year was 23,620, as compared with 23,474 in 1926.

## Correspondence.

### TREATMENT OF GASTRIC AND DUODENAL ULCERATION.

SIR,—I have read the communications by Professor MacLean in the last number of the *British Medical Journal* (p. 619) and in the *Lancet* of January 7th with very great interest, for, like many surgeons, I have long held that the treatment of ulcers of the stomach and duodenum by operation is at best a crude and temporary method, which ought to be replaced by medical measures.

The administration of large doses of alkali would seem to be the most rational method of treatment, for my experience has been that with gastric ulcer the acid is in the upper limits of normal, and is considerably raised with pyloric and duodenal ulcers. I have also frequently shown that the occurrence of gastro-jejunal ulceration is almost entirely dependent upon the presence of a high acidity, and hence is practically only found with pyloric and duodenal ulcers and in the male sex. The question, however, is whether under modern conditions of civilized life the administration of large doses of alkali can produce so permanent a cure that a patient is able to return to his work and to live on a normal diet. Up to the present time physicians and surgeons have both produced a large amount of evidence to show that certain ulcers can be so treated with satisfaction, whereas others will require operative intervention, and the differences of opinion which have arisen have centred rather round the question of what is the definition of a gastric ulcer.

The choice of treatment has been most ably discussed in a recent paper of Dr. Izod Bennett in the *Journal* of February 4th (p. 168), a paper which should be read by everybody interested in the subject of gastro-duodenal ulceration; but in this paper the variation in definition is made evident, for Dr. Bennett mentions two groups which ought to be treated surgically, and four others which probably will require surgical treatment. He goes on to say, however, that the remainder probably form 80 per cent. of the total, whereas to most surgeons there is little or no remainder, and therefore we are inclined to say that all cases of chronic gastric ulcer should be treated surgically. The 80 per cent. of Dr. Bennett either do not come to us because they are relieved by medical treatment, or, if seen by us, are diagnosed rather as acute

ulcers or erosions. Professor MacLean, on the other hand, claims that those ulcers which we should all group as chronic are cured by alkaline treatment, and it is important to consider the value of these claims. As Professor MacLean admits in the correspondence following his first article, the alkaline method is not new: in fact, his treatment is almost identical with that taught me by the late Dr. F. J. Smith when I was his student in 1903. Hence there has been plenty of time for it to have been adequately tried, and up to the present no large series of figures has ever been published showing a high percentage of satisfactory results.

Professor MacLean states that his results are based on five years' experience of this method, and it is possible that he has obtained lasting cures thereby, but he produces no convincing evidence that such is the case. In his present paper he quotes at length four cases, every one of which has only been treated for four months or less, and in his previous paper in January only one had come under treatment for a period of longer than a year. Now if there is one point in the symptoms of chronic ulcer which has been appreciated by surgeons, it is that there is a definite periodicity, and that many patients may remain absolutely free from symptoms without any treatment whatever for periods up to six months or a year. Hence it is wholly incorrect to state that because these patients have remained well since the alkaline treatment was instituted they were permanently cured. Moreover, the continuation of such medical treatment is associated with very considerable danger. Since Professor MacLean's paper was published there have come under my care four cases in which the so-called "MacLean treatment" has been carried out in the larger London hospitals without any relief, and when I operated upon them they were found to have inoperable carcinoma. It is only begging the question to say that chronic ulcers do not become carcinomatous, an opinion with which many—including myself—do not agree. The fact remains that many conditions diagnosed as ulcer become or are carcinomatous.

That the danger of perforation and hæmorrhage is not overcome by alkaline treatment has long been realized, and my experience has been in exact accord with that of Sir Berkeley Moynihan—namely, that the majority of cases upon which I operate have undergone many courses of such medical treatment, only to have a recurrence, often with dangerous symptoms. As against this, one has to consider what are the results which are to be obtained by surgical treatment. In an article now in the press, which I have written for the *Nelson Surgery*, I have investigated all my cases of ulcer that have been operated upon up to date; these number some 1,200, and the results show that between 80 and 90 per cent. of them are cured, but the investigation of a series of cases varying from one to fifteen years is very difficult to estimate with accuracy. From this point of view the statistical inquiry concerning cases operated upon from 1920 to 1924 which is being carried out by the British Medical Association will be of very great value, and it is to be hoped that it will institute a similar investigation of the value of medical treatment. The analysis of my own cases for this report has been much more laborious than I had anticipated, and hence I have only completed up to date the group of pyloric ulcers, but these show that 86.5 per cent. of the total are cured, or, eliminating three cases that have been lost sight of, 90.6 per cent. are cured.

Unfortunately some dispute has fallen upon the surgical methods by reason of some curious figures which have been published, as in Mr. Pannett's paper in your last issue (p. 623). There is no doubt that the immediate mortality and the incidence of complications are inversely proportional to the technical skill of the operator, and therefore it is not fair to accept Mr. Pannett's statement that the mortality for gastro-enterostomy is from 4 to 5 per cent. In my earlier cases the mortality was between 2 and 3 per cent. for simple gastro-enterostomy, but in my last series of 150 cases there has been no death. In the same way errors of technique, such as the use of Murphy's button or of silk sutures, greatly increase the incidence of gastro-jejunal ulcer. I have frequently shown that, taking all ulcers, the incidence of this complication is 1.8 per cent., while for duodenal ulcers it is about 3 per cent.

It is also curious to note that Mr. Pannett states that "the liability to haemorrhage from a gastric, but particularly a duodenal, ulcer is about as great after an operation as before." This statement is difficult to accept. I have shown that in my own series haemorrhage occurs with duodenal ulcer in about 25 per cent. of the cases. I have never known a duodenal ulcer persist after a well-performed gastro-enterostomy, and every case of haemorrhage that has occurred after an operation has been due to a gastro-jejunal ulcer—that is, it occurs in 2 per cent., or less, of the total. With the growing demand for operative treatment and the increase in the number of smaller hospitals these operations have unavoidably to be carried out by those whose opportunities for performing them occur but seldom, and since with us all experience does much to decrease both the mortality and the frequency of after-complications, the results so obtained must of necessity be relatively poor; but it is unjust to blame the operative measures for such complications. The results of carefully performed operations are based upon large series of figures, and at present no evidence has been produced that they can be equalled by medical treatment.—I am, etc.,

London, W.1, April 16th.

A. J. WALTON.

### THE HEALING OF PERFORATED ULCERS.

SIR,—Mr. Pannett, in his interesting address, states that probably about 50 per cent. of perforated gastro-duodenal ulcers are cured by simple suture. I am inclined to think that the percentage is considerably more. For many years I did not do primary gastro-enterostomy in these cases, but told the patients to return in about six weeks for the anastomosis to be made. In nearly all there were still signs of ulceration or thickening.

At last a man was not readmitted until three months after the perforation. I opened the abdomen intending to do a posterior gastro-jejunostomy, but could find nothing to warrant it. There was no trace of ulcer, thickening, or pyloric stenosis. The only sign of the previous condition was the patch of gastro-hepatic omentum which had been fixed over the line of suture. The abdomen was closed and the patient was discharged in three weeks, looking and feeling quite well. He was told to come back if he had any trouble, but has not done so.

Since then I have done very few second operations in these cases.—I am, etc.,

Lancaster, April 16th.

A. S. BARLING.

### THE EXPECTANT MOTHER.

SIR,—In view of Dr. Barford's plea in the *Journal* of March 31st (p. 571) for further efforts on the part of local authorities, I think the experience of the Bristol Royal Infirmary may prove of interest.

In 1919 an ante-natal clinic was established in connexion with the maternity department of this institution and became an immediate success. I need not enlarge upon the great benefits it has conferred on the patients, or the importance of the teaching facilities to the medical students (attendance is compulsory) and pupil midwives. There is, in addition, an infant welfare centre and post-natal clinic conducted by specialists. During last year 1,400 new patients were seen and practically all of them attended regularly; 1,200 were treated during their confinement by the Royal Infirmary—700 in the wards and 500 in the district. The remaining 200 were accounted for by premature labours, removal from Bristol, and about 120 "consultation cases" from private doctors and municipal clinics.

As the total birth rate registered by the city authorities is below 7,000 it will be seen that the Royal Infirmary deals with about one-fifth of the expectant mothers of Bristol at this clinic. Dr. Lily Baker has been appointed special assistant physician in charge of the ante-natal work.

I approached the local authorities in hopes of getting some help in this important work, but was met with a blank refusal for two years. I then applied direct to the Ministry of Health, who were most courteous and helpful, and sent Dame Janet Campbell to look into the situation. She expressed the opinion that we ought to get "a good

annual grant and a capital sum to start off with." Letters to that effect are in the possession of the secretary to the Royal Infirmary.

After much delay I again approached the local authorities and was asked to explain the situation to a meeting of the health committee. At the end of a long discussion it was proposed that the health authorities should pay £200 per annum and close one of their own clinics, which cost that amount annually, sending these cases to the Royal Infirmary. This very feeble offer was accepted as being better than nothing. The infirmary clinic is held three days a week, and if the municipal rate of salary of £1 1s. per clinic was paid to Dr. Baker it would leave about £40 a year towards the Royal Infirmary in its ante-natal work. Dr. Baker generously offered to hand over the salary to the treasurer of the Royal Infirmary.

To my surprise, when the agreement came to be signed it was made a condition that the town council should have a member placed on the Royal Infirmary committee, and that the municipal patients should not be seen by students. The infirmary committee did not see their way to accept these conditions, and the offer lapsed. I understand from Professor Rayner that exactly the same thing happened at the Bristol General Hospital, where some 800 cases are dealt with annually.

While I know that the municipal clinics are most efficiently and carefully run, and are doing excellent work, I feel sure that everyone will agree that ante-natal clinics at teaching hospitals, where it is possible to send the patients to cardiac, dental, and other clinics, are at any rate equally efficient, and equally deserving of help and support. I then applied once more to the Ministry of Health, pointing out that the Royal Infirmary and General Hospital together saw one-third of the expectant mothers of Bristol, many of the cases being "consultations." I received a most sympathetic letter, which showed that the local health authorities were the cause of our receiving no help in spite of the strong recommendations of the Ministry in London.

In view of my experience I feel that Dr. Barford is unlikely to see his excellent suggestion carried out when local authorities can disregard the advice of the Ministry of Health, unless he is so fortunate as to have an enlightened health committee to deal with, as in the case of Cardiff, where, I am told by Professor Maclean, about £2,000 a year is received by the Cardiff Royal Infirmary to enable them to do their best for the maternity work among the poor of the city.—I am, etc.,

R. S. S. STATHAM, M.D., Ch.M.,  
Honorary Gynaecologist, Bristol Royal Infirmary.

April 4th.

### TREATMENT OF ACUTE PNEUMONIA.

SIR,—As one who has also read with pleasure the letters of Dr. Mallow and Dr. Thompson, I wish to record my belief that the sentiments which the writers express are shared by the majority of medical practitioners, and in this district at any rate the practice is on the lines which Dr. Thompson advocates.

It is in pneumonia more than in any other disease that the physician is called into consultation, and so gets many opportunities of seeing what form of treatment is being carried out.

I find very little use being made of oxygen, or powerful or nauseous drugs or vaccines or serums. In nine cases out of ten the doctor avoids disturbing the patient for purposes of examination, having once made his diagnosis. As for the discomfort of the bed-pan, it is now quite common to find that no special anxiety is felt about the bowels acting at all during the height of the fever.

Yet satisfactory as it is to stand by whilst Nature performs her cure, I think we are all alive to the possibility that one of these days some remedy will be forthcoming which will reduce the present mortality of pneumonia, and I fail to see how any remedy or preventive can be proved unless someone is prepared to try it. A spirit of enterprise tempered with caution and an honest endeavour to do no harm should not be discouraged.—I am, etc.,

Birmingham, April 14th.

LEONARD G. J. MACEY.

## GLAND GRAFTING AND INHERITANCE.

SIR,—If Dr. Norman Haire will carefully reperuse my letter in the *Journal* of March 31st (p. 570), he will, I think, realize the non-justification of his statement in the following issue (p. 610) that I had "written under a complete misapprehension of the nature of the various testicle-grafting operations." The main purport of my letter was to suggest that, even if either of the two suppositions of Dr. Voronoff and his followers—that the "new testicular material replaces or reinforces the physiological action of the animal's own testis"—be true, the fact does not constitute evidence of the transmission of acquired characters. Incidentally, I pointed out that if the *modus operandi* be the first of the two hypotheses advanced, the fertilizing agents, wherewith the rejuvenated hull Jacky sired nine calves must have had their origin in the imported gland tissue. If, as Dr. Haire says, this is not the case, then clearly the alternative hypothesis of Dr. Voronoff and his school—that the foreign gland replaces the physiological action of the animal's own gland—must be ruled out of court, and there remains as explanation of the alleged inheritance phenomena a mere tonic effect upon the latter of the introduced glandular tissue.—I am, etc.,

CHARLES M. BEADNELL,  
Surgeon Rear-Admiral, R.N.

Aberystwyth, April 8th.

ACHALASIA OF THE CARDIA (SO-CALLED  
CARDIOSPASM).

SIR,—I have no hope of persuading Dr. Brown Kelly of the error of his views, but his last letter (April 7th, p. 610) so seriously misstates the evidence in favour of achalasia and against cardiospasm that it calls for a reply.

It is not clear what he can mean by cardiospasm, as he denies the existence of a cardiac sphincter. But whereas the greater part of the oesophagus always has a potential lumen, the lowest inch, which constitutes its intra-abdominal portion, is closed and forms a physiological sphincter, as can be easily seen with the *x* rays, and as Dr. Brown Kelly apparently realizes when he speaks of a "cardiac canal." That this represents an anatomical sphincter has been demonstrated by Poulton, myself, and others.

The inflammation and subsequent degeneration of Auerbach's plexus found by Stokes and Rake, and more recently by Cameron, must result in failure of the sphincter to react to stimuli. The sphincter cannot, therefore, perform its normal function of relaxation nor its rarely exercised power of contraction; it consequently remains closed—that is, in its normal position of rest. This, with secondary dilatation of the oesophagus, is what occurs in animals when the vagi are divided. The changes found by Cameron in Dr. Brown Kelly's fatal cases are obviously incompatible with his theory of spasm.

In the vast majority of cases reported both in England and abroad no hypertrophy of the sphincter was present. In a severe case of mine in which the patient was cured by longitudinal incision of the sphincter, Mr. R. P. Rowlands, who operated, was astonished at the extraordinary tenuity of the muscle, and he demonstrated to all who were present the absence of any spasm in the closed sphincter, which was over an inch in length and extended from the opening in the diaphragm to the stomach. I expect that the exceptional cases in which hypertrophy is found represent those mentioned in my last letter (March 24th, p. 521), in which secondary temporary spasm occurs as a result of the accompanying oesophagitis in the earlier stages, before the degeneration of Auerbach's plexus is complete.

When spasm is present considerable resistance is felt to the passage of the mercury tube, which is tightly gripped when it eventually enters the stomach, exactly corresponding with what occurs in anal spasm—a most appropriate comparison. This is in striking contrast with the complete absence of resistance and gripping noted by all observers in uncomplicated cases, and in the rare cases with temporary spasm when the latter is overcome as a result of treating the oesophagitis.

Dr. Brown Kelly apparently regards the forced passage of a rigid oesophagoscope in the recumbent position under

an anæsthetic as a more natural method of examination than allowing a flexible mercury tube to be dropped by the patient himself through his sphincter. As a matter of fact, the mercury tube closely approximates to what happens under natural conditions, because the closed sphincter gives way when the column of food in the oesophagus exceeds a height of about eight inches, closing again as soon as the eight-inch level is reached. It is in this way that nutrition is maintained. The weight of the mercury tube is about the same as that of the column of food in the dilated oesophagus. On the other hand, it is difficult to pass a rigid instrument past the angle formed by the sphincter with the rest of the oesophagus, particularly when the latter is so dilated that its lower extremity is actually below the entrance to the sphincter. It was for this reason I introduced the mercury tube to replace rigid bougies, which could only be passed with great difficulty. I have no doubt that Dr. Brown Kelly has mistaken the spasm of the diaphragm caused by the pressure of his instrument for spasm of the cardiac sphincter, which is actually within the abdomen and not within the thorax. Many of the earlier oesophagoscopists recognized that the spasm was diaphragmatic, and actually regarded this as the cause of the condition.—I am, etc.,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest,  
April 9th.

## THROMBO-PHLEBITIS MIGRANS.

SIR,—I read with great interest in your issue of April 7th (p. 586) the account given by Professor Moorhead and Dr. Abrahamson of a condition which they call "thrombo-phlebitis migrans." The authors say they can throw no light on the etiology, though they state that the method of spread suggests forcibly the presence of a blood infection.

I might mention that in an essay on "influenza in general practice," written in 1925, I drew attention to the commonly observed occurrence of venous thrombosis in practice ever since "influenza" returned in 1918. In the same place I described the pulmonary and mesenteric phenomena now mentioned by Drs. Moorhead and Abrahamson, and showed that the former were often wrongly diagnosed as "pneumonia" and "pleurisy," and the latter were often confused with appendicitis and intestinal obstruction. I attributed the pulmonary symptoms to infarction and the abdominal to mesenteric embolism. Further, I noted that cerebral, coronary, and renal (nephritis and haematuria) embolism were often associated with influenzal attacks, or occurred during influenzal seasons. It is true that thrombosis in peripheral veins was not seen in all my cases, but I assumed that there must have been thrombosis somewhere in these cases. The process must be the same, and it is only a matter of accident where the thrombosis occurs. In some of my cases of pulmonary infarction (or thrombosis) jaundice and intense anaemia were observed; both these phenomena strongly suggested the presence of a haemolytic streptococcus.

As jaundice and anaemia were often seen in cases of influenza with no sign of thrombosis, it was natural to suppose that the thrombotic cases were related to influenza. In fact an initial diagnosis of influenza was made in most of the thrombotic cases. A chronological study over ten years of these thrombotic and embolic cases settled the matter beyond doubt. The fact that they almost invariably occurred when the influenza curves rose, and were rarely seen when influenza became scarce, seemed conclusive evidence of the importance of influenza in the production of venous thrombosis and embolism. In the ten years 1918-27 there have only been three (1920, 1921, and 1925) without an epidemic; it is not to be wondered, therefore, that venous thrombosis is fairly common. Yet I believe the symptoms produced by it are often not appreciated by those unacquainted with epidemiological happenings.

It is of interest to note that Dr. Whittingdale of Sherborne, Dorset, reported seeing in general practice in the twelve months prior to March, 1926, a large number of cases of phlebitis of the lower limbs with a "large proportion of pulmonary infarcts," and, in one case,

"multiple cerebral emboli." Dr. Whittingdale, like myself, looked upon the pulmonary and cerebral complications as being due to embolism. Drs. Moorhead and Abrahamson are at pains to show that embolism was not present in their cases. Most of the pulmonary cases I have seen have come on rapidly with acute chest pain, pleural rub, and the spitting of characteristic blood-spit, and were certainly instances of pulmonary embolism. Many of them, further, have occurred in close chronological proximity to cases of pulmonary embolism after operation, confinement, etc.

I have seen a very large number of these pulmonary mesenteric, cerebral, and renal thromboses (or embolisms) in the last ten years, so many, indeed, that I wrote in 1926 an essay with the title "The infective factor in embolism"; this has not been published, but most of the points now raised by Drs. Moorhead and Abrahamson appear in it. I would suggest that thrombo-phlebitis migrans as described by the latter is not unconnected with the influenza which every panel doctor knows only too well to be constantly with us.—I am, etc.,

ARMORSE W. OWEN, M.D., B.S. Lond.

Aberdare, April 7th.

#### THE CAUSES OF ALCOHOLIC INEBRIETY.

SIR,—The interesting discussion on this subject which was reported in your issue of April 7th (p. 594) leads us to give some details of the experience obtained here. Obviously the essential cause of inebriety is the actual drinking of alcoholic beverages. Never to have taken alcohol in any shape means never to have come under the primary cause. No total abstainer ever becomes alcoholic. Then follow a large number of causes: heredity, habit, stress and strain, a psychomotor stimulus to obtain a euphoric affective tone, the assuaging of conflict, and the attainment of freedom of expression for repressed forces.

From a survey of the many hundreds of patients who have passed through the two institutions of the Norwood Sanatorium—Beckenham and Rendlesham—it is clear that heredity is a decided cause, not a mere conjecture. It is this hereditary influence, "the inborn soil ready for the seed," which has given rise to the rather exaggerated belief that "the alcoholic is, before he even touches a drop, an abnormal person." Persons with an alcoholic parentage should remain total abstainers, if they would remain free from danger. But it is another hereditary factor that also appears again and again—namely, that which is popularly called the "nervous" or "unstable" type of individual. Here again total abstinence is the dictate of "safety first."

Habit undoubtedly, together with ease of access, plays a large part in many a downfall. But there have been quite an appreciable number in whom heredity and habit seemed to be absent as causal factors. These have been those who have had recourse to alcohol "as a drug to overcome stress and strain, or to drown distress and pain"—in short, for its narcotic action. It is here also that the psychomotor stimulus to obtain a euphoric affective tone is so powerful, and, once started, the desire for more may become overpowering. A man—a weak man, and often a lazy one—takes alcohol because it does seem really to assuage conflict, and to allow him to perform those repressed actions with "a clear conscience."

In the methods of treatment adopted the first aim should be to rid the inebriate of all alcohol; the second to bring him back, as far as possible, into a healthy state of mind and body, and then to re-educate his will to a higher plane of living. It is here that treatment away from friends and business has in so many cases proved permanently successful.

Investigation is still being carried out as to any histological and chemical changes in the blood of the inebriate, and it is possible that results may indicate further causal factors and improved lines of treatment.—We are, etc.,

A. W. GEORGE.

GEORGE F. VINCENT.

#### THE ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—Every year, almost contemporaneously with the advent of the cuckoo, I am assailed by letters soliciting my vote for one or other of the candidates for election to the Council.

These may be divided into four categories: (1) From a Fellow that I know well about a Fellow that I know well; (2) from a Fellow that I know slightly about a Fellow that I know well; (3) from a Fellow that I know well about a Fellow that I know slightly; (4) from a Fellow that I know slightly or not at all about a Fellow that I know slightly or not at all.

Most of them are typewritten, but many have appended to them, by way of signature, a hieroglyphic which can only be decoded by reference to the printed address and the *Medical Directory*. This is perhaps not surprising if, as would sometimes appear to be the case, the writer is circularizing all the Fellows of the College.

Apart from occasional references to the advantages which would, in the writer's opinion, accrue from the presence of a provincial surgeon or of a specialist on the Council, the tenor of these letters is peculiarly consistent. It is to the effect that the Fellow in question is an excellent surgeon, is an admirable teacher, is consumed by a passion to spend his days in sitting on committees, and would be an ornament to any society of which he might be elected a member. I am prepared to believe that in every case these statements are wholly true, but I doubt if they have ever affected the result of an election in any appreciable degree. It is obvious, for instance, that letters in the first two categories are supererogatory, and it is unlikely that a letter in the last would induce a conscientious voter to reconsider a course of action upon which he had already decided. I believe, therefore, that this output of propaganda is to all intents and purposes valueless, and I am convinced that it would be more dignified to conduct the election without it.

I would like to add that it is not many years since the electorato of Chicago was approached by similar methods. But when it was discovered that canvassing by post had little or no effect its place was taken by the throwing of bombs into the houses of the opposing candidate or candidates. American methods have before now been known to permeate this effete Continent, and if this one succeeds in doing so I shudder to think what life may be like in Harley Street in a few years from now.—I am, etc.,

London, April 13th.

IVOR BACK.

#### TREATMENT OF PROSTATIC ENLARGEMENT.

SIR,—In reply to a letter of Dr. J. Curtis Webb in the *British Medical Journal* of December 3rd, 1927 (p. 1053), referring to the treatment of enlarged prostate by x rays, I would like to say that I have had a similar satisfactory experience. If he will refer to the *Australian Medical Journal* of May, 1911 (pp. 214-18), and of December, 1912 (pp. 817-18), he will find reports by me on a series of cases so treated.

For two years or more, up to the time I left Ballarat, no prostatectomies were performed at the Ballarat General Hospital, all cases of enlarged prostate being referred to the x-ray department for treatment, so successful were the results of x-ray treatment.

Since starting in Melbourne after the war I have had several cases, and all have been relieved. The last case astonished me. The patient was over 70 years of age, with large calculi in the lower end of both ureters. He declined operation, but was so much relieved by the treatment that he was able to discard his catheter, that had become absolutely necessary to him, and left for the country, where he lived. His health was greatly improved. Since then I have not heard of him.

Why this method of treatment is not more universally employed I cannot understand, as relatively small doses only are necessary to achieve the desired result. (I give about one-fifth or a quarter of a unit skin dose or less, twice a week, at 100 kilovolts through a 4 mm.

aluminium filter, the patient sitting on a special chair with a tube under it.) As a rule relief begins on the tenth day after the first raying. If no improvement is manifest in a fortnight operation can be performed without the treatment in any way complicating it. I found that patients over 60 years of age give the quickest results, but with more penetrating radiations I should think the treatment would be equally effective in younger patients.

It is interesting to note that my early successes were achieved with a 12-in. coil, one milliamperes of current, and a 6-in. spark gap through a filter of one only millimetre thickness of aluminium or glass.—I am, etc.,

Melbourne, Feb. 14th.

CHAS. E. DENNIS, O.B.E., M.D.

#### DELAYED NOTIFICATION OF TUBERCULOSIS.

SIR,—Much has recently been spoken and written regarding the late notification of cases of tuberculosis, and statistics have been published indicating that in the county of London an average of 47 per cent. of cases of tuberculosis die either unnotified or within three months of notification.

I have attempted to throw light on the subject by looking into the figures for the borough of Lewisham, and have to report as follows:

During 1927 there were 175 deaths from pulmonary tuberculosis and 20 from other forms of tuberculosis in the borough—a total of 195. Of this number 37 cases of pulmonary tuberculosis and 20 cases of non-pulmonary tuberculosis were either unnotified or notified within three months of death—a total of 29 per cent.; that is to say, nearly a third of the deaths were notified late or not at all. Going into detail, I find that of the 20 non-pulmonary cases 14 died from tuberculous meningitis, 2 from acute peritonitis, and 4 from tuberculosis of other regions, none of the 20 having been ill for three months prior to death. Of the 37 pulmonary cases 31 were notified within three months of death, while 6 died unnotified. Of the 31 dying within three months of notification 12 died from acute phthisis (3 of them suddenly), 7 had never previously attended a doctor, 3 were strangers, having only recently removed to the borough, and 4 were wrongly diagnosed—1 as bronchitis and emphysema, 1 as bronchitis and asthma, 1 as pleural effusion (sudden death), and 1 as a wasting child (died from military tuberculosis). Five had been ill and had attended a doctor—2 for six months, 1 for a year, 1 for two years, and 1 for forty-five years. Of the 6 unnotified cases 1 had been notified three years previously, had left the borough, and then returned without the knowledge of the authority, 1 died from a sudden haemorrhage, 1 was diagnosed at the necropsy, 1 was not previously diagnosed, and 2 had been under doctors for three months and many years respectively.

Thus of the 57 cases, only 7 could reasonably have been notified at an earlier date, bringing down the figures from 29 per cent. to 3.5 per cent. It would be interesting to know whether these figures tally with those of other districts.—I am, etc.,

ROSE JORDAN, M.D., D.P.H.,  
Tuberculosis Officer for Lewisham.

Catford, S.E., April 3rd.

#### THE "CURE" OF PULMONARY TUBERCULOSIS.

SIR,—There appear to be three distinct lines of action in Dr. W. M. Crofton's method of treating pulmonary tuberculosis: (1) tuberculin therapy, (2) vaccine treatment of so-called secondary infection, and (3) the use of iodine.

It is only in respect of Dr. Crofton's use of tuberculin that the following remarks are offered. H.T.S. (human type tubercle bacillus solution) is stated to contain 1 mg. of dissolved tubercle bacilli in each cubic centimetre. The bacilli are dissolved in benzoyl chloride. "The largest dose of this solution required is .01 mg." (I quote from Dr. Crofton's book). If this figure refers to the weight of dissolved tubercle bacilli it indicates that Dr. Crofton works with quantities of bacillary substance under a maximum of 0.01 mg.; if the figure refers to the solution itself it indicates a very much smaller quantity. In either case there is here a crucial departure from Koch's method, in which the greatest importance is attached to high dosage, and in which the maximum both with T.R. and B.E. is 20 mg. solid bacillary substance—a dose two thousand times greater than the maximum dose of 0.01 mg. mentioned above. Koch himself states that "at the

beginning of immunization such small doses are given (0.002 mg. T.R.: 0.0025 mg. B.E.) that no immunity worth speaking of is to be expected, and that first when one arrives at larger doses of 1/2 to 1 mg. unmistakable evidences of immunization present themselves." Again, "in the immunization of the sound and the treatment of the sick it all comes to the use of as large doses as possible." And in his last pronouncement, made in 1909 in the preface to the third edition of Bandelier and Roepke's textbook, he expressly declared "that it is beside the purpose to stand still with the minimum doses which are often employed, one must not forget that it is a matter of active immunization, and that it can only be advantageous for the sick if not too small a degree of immunity is reached."

Another important point is Dr. Crofton's departure from Koch's classical method of comminution of the bacilli in favour of the application of benzoyl chloride as a solvent. This interesting method, which was first developed some twenty years ago by Deycke in his search for a solvent or activator of nastin, the leprosy tuberculin, may or may not be an improvement on Koch; it would be interesting to have the results of comparative experiments. But the only evidence on this point which Dr. Crofton offers is that "the clinical results with tubercle bacilli dissolved in benzoyl chloride have been so satisfactory."

Considering the dosage employed, the complexity of the treatment, and the complexity of the problem, one feels that some further body of evidence will require to be produced in favour of these two important departures from Koch's classical methods to entitle them to preferential consideration.—I am, etc.,

Wandsworth, S.W., April 7th.

ROBERT CARSWELL.

SIR,—The letters of Drs. Crofton and Weatherhead are interesting as showing that the subject of tuberculin is still alive and that work is being done. Neither writer distinguishes between the two great classes of pulmonary tuberculosis victims; it is on this vital point that many investigators stumble. The first class includes cases in which the disease is acquired in infancy or early childhood, and the second those in which it is acquired after puberty. Patients who have survived after an early infection which may have shown itself as a bronchitis, pneumonia, marasmus, or retarded growth are benefited by injections of bovine tuberculin (P.T.O.), and after puberty by Koch's "old tuberculin."

Patients infected after puberty recover, if the disease is not too far advanced, when removed from the source of infection. If circumstances do not permit removal an increased resistance may be obtained by weekly injections of Koch's "old tuberculin." Observations on this subject are of doubtful value when the date and source of the infection are not ascertained. I think the following instances are worthy of record. Two families of children under my care remained more or less stationary while receiving weekly injections of tuberculin, the younger ones taking P.T.O. and the older ones O.T. At my suggestion the mothers submitted themselves for injections; both were substantial heavy women in the early forties. One two-hundredth of a cubic centimetre of Koch's "old tuberculin" gave in each mother a profound reaction, and sloughing at the site of the injection, which ended in improvement in both families. Though I have seen definite cures in advanced cases, I have also encountered disasters; my best results occur when the source of the infection has been more or less definitely ascertained and, if necessary, treated.—I am, etc.,

Buxton, April 8th.

R. CRAWNSHAW HOLT.

#### THE HAEMORRHAGIC DIATHESIS.

SIR,—Dr. H. L. Tidy, in his interesting and enlightening article on the haemorrhagic diathesis (April 7th, p. 583), considers it impossible to say whether the reduction in platelets precedes the increase of haemorrhages or vice versa, and mentions Forster's case in which, although the haemorrhages ceased spontaneously, there was no rise in platelets until three days later. May it not be that all

the platelets produced by the marrow became adherent to defects in the capillary endothelium, and that until these defects required no more platelets, no increase would appear in the blood? So long as the platelets were being massed as fast as they were made, the microscope would not show any appreciable increase, and because haemorrhages had ceased it does not follow that no further massing of platelets was necessary. Then again, in Foerster's patient the marrow might have been taxed to the point of exhaustion just at the time of cessation of haemorrhage, and three days were necessary for recovery. Had Foerster given his patient an injection of some solution to destroy the platelets just after the spontaneous cessation of the bleeding he might have found that the haemorrhages recurred. If, however, they did not reappear, then he might conclude that the platelets did not bring about the cessation of haemorrhages.—I am, etc.,  
Yelverton, South Devon, April 8th.

R. DAVIS, M.D.

#### CLINICAL OPPORTUNITY FOR MIDWIFERY.

Sir,—In recent discussions on maternity problems the point of view of two quite important people has not emerged. I refer to the maternity patient and her husband. In this village working men consider it a point of honour to provide their wives with a doctor's services at confinement, hoping thereby to secure for them greater alleviation, and perhaps a more speedy and secure delivery. The accoucheur whose bag contains the chloroform bottle will always retain a considerable part of ordinary midwifery practice. But the medical student's clinical experience is lessened because midwifery opportunities are given to C.M.B. candidates who desire the qualification, but do not intend to practise.

If more opportunity for the medical student is desirable, a stricter rationing of clinical material is surely necessary.—I am, etc.,

Peppard Common, Oxon, April 2nd.

E. L. CARLING.

### Medico-Legal.

#### STANDARDS OF SOBRIETY: MORE MAGISTERIAL DICTA.

A FURTHER case illustrative of the difficulty of obtaining any clear legal definition of what constitutes drunkenness was heard in the Marylebone police court on April 16th, when a man was charged with being drunk in charge of a motor car. The divisional police surgeon gave details of his examination, and stated that he formed the opinion that the man was drunk; he admitted, however, on cross-examination, that if this had been an ordinary case of a person charged with drunkenness he would have said that he was sober. The magistrate, Mr. Bingley, thereupon remarked, "Well, that is the end of this case." The police surgeon said the man's incapacity depended on what he was charged with doing, and Mr. Bingley replied, "You are totally wrong. That is not the law." When the witness stated, "A doctor has no means of determining whether a man is drunk unless he is considering the particular thing the man was doing, or failed to do," the magistrate said, "If that is so you need not bother about all these tests." Giving his decision, Mr. Bingley said that the law used the expression "drunk," and in a case before the superior court the Lord Chief Justice stated that "drunk meant drunk." All he (the magistrate) had to do was to be satisfied that the man charged before him was or was not drunk. It might be advisable that the law should be altered. All sorts of phrases could be imagined to describe that culpable condition, but the law as it stood said "drunk." The doctor had said at the end that he thought the man was too drunk to drive a car; but that was not the law. It had nothing to do with the doctor whether the man was in charge of a car or was lying in the street; the sole question was whether he was drunk. In view of the doctor's evidence he was not satisfied beyond all reasonable doubt that the charge had been proved, and the accused would be discharged. A similar view was recently expressed, also at Marylebone (reported in the *Journal* of March 31st, p. 573), by another magistrate, Mr. Hay Halkett, in a case of the same kind.

#### HUSBAND'S RESPONSIBILITY FOR WIFE'S TREATMENT.

AT Common Law a wife can pledge her husband's credit for necessities suitable to the position he allows her to assume, and his Honour Judge J. W. McCarthy, in the Harrogate County Court, has recently held that treatment received by a wife in the private ward of a hospital comes within the category of a necessary where the husband is a man well able to afford to pay for it. The defendant was Mr. Norman Hudson of The Gables, Pannal, a landowner and a member of the Bramham Moor Hunt, and he refused to pay for his wife's treatment for scarlet fever in a private ward at the Harrogate, Knaresborough, and Wetherby Joint Isolation Hospital. Mrs. Hudson was placed in a private ward at her own request, and when the matron showed her a letter in which her husband repudiated liability shortly after her admission, she observed: "It is just like him. I am his wife, and he will have to pay. He is a well-to-do man." The defendant was a most unsatisfactory witness on the relevant evidence as to his means, but ultimately he had to admit that he hunted twice a week, kept a large stable, owned a large car, and was co-owner with his brother of a large amount of land in the neighbourhood of Harrogate. From these facts it appeared evident to the judge that treatment during illness in a private ward of a public hospital rather than in one of the public wards at the expense of the rates was a necessary suitable to the wife's position in life. His Honour found it difficult to express in measured terms his opinion of the conduct of a sporting landowner trying to force his ailing wife into a public ward of a hospital rather than pay six guineas a week for accommodation and treatment suitable to her station and habits in life.

#### Obituary.

RICHARD LANE JOYNT, O.B.E., M.D., F.R.C.S.I.,  
Surgeon to the Meath Hospital, Dublin.

WE much regret to announce the death, on April 4th, from pneumonia of Mr. Richard Lane Joynt, the distinguished Dublin surgeon. A native of Limerick, he received his early medical education at Trinity College, Dublin, obtaining the diploma L.M. in 1889, and graduating M.B., B.Ch., B.A.O. in the following year; he proceeded M.D. in 1892, and obtained the Fellowship of the Royal College of Surgeons of Ireland in 1894. Election to the surgical staff of the Meath Hospital and County Dublin Infirmary followed, and at the time of his death Mr. Lane Joynt was senior surgeon to that institution. He was a member of the Council of the Royal College of Surgeons, and had been for some years one of its examiners in surgery. During the war he served in the Royal Army Medical Corps with the rank of lieutenant-colonel, and for his war services, more especially in connexion with orthopaedics, he received the O.B.E.

We are indebted to Sir THOMAS MYLES, F.R.C.S.I., his lifelong friend, for the following appreciation of the man and his work.

By the death of Mr. Richard Lane Joynt the surgical profession has lost one of its most remarkable personalities. To the general public he was merely a surgeon of repute, discharging quietly and efficiently his daily work in a large clinical hospital, the Meath, and amongst his private patients. Within the surgical profession itself he was much better known, and the respect and admiration felt for his remarkable talents were both intense and profound. He was indeed a remarkable personality. To a thorough knowledge of his profession he added a most intimate acquaintance with the technicalities of almost every kind of handicraft. He was a metallurgist and mechanician of a very high order, and possessed extraordinary skill in the manipulation of the tools of craftsmen who work in wood and metals. This skill and knowledge were ever at the disposal of his friends and colleagues, and many of the most successful results in the treatment of grave injuries in the Dublin hospitals were due to apparatus, often quite original in design, not merely suggested by him, but actually made with his own hands in his own workshop. During the great war his capacity and aptitude in this

branch of surgery was brought under the notice of the Imperial Government, and he was gazetted a lieutenant-colonel in the R.A.M.C. and appointed general inspector of orthopaedic factories in Great Britain and Ireland. Sir Robert Jones, the great orthopaedic specialist, who was principal medical officer in charge of the maimed victims of the war, soon learned to appreciate the rare gifts of his subordinate, and set him the task of designing apparatus, often of the most complicated character, to meet the very diverse demands which the tragedies of the war had produced. Many maimed victims of the war who have lost more than one limb have had their lives made tolerable and their capacity for useful work increased a hundredfold by the apparatus designed, and in many cases actually made with his own hands, by this modest Irish surgeon who has just passed from us. At an earlier stage in his life he was one of the pioneers in x-ray work, and, like too many of these pioneers, paid a terrible price for his enthusiasm. Before its dangers were known, and the means for guarding against them had been developed, he was attacked in the hands, and for many years suffered agonies which he bore with his characteristic uncomplaining fortitude.

Apart from his professional and mechanical skill, he was a scholar of wide range and taste. He possessed an acute intelligence and a retentive memory, and this, with the extraordinary catholicity of his taste and studies, made him a most interesting and delightful companion. English literature had in him a most fervent worshipper. The works of Shakespeare, Goldsmith, and Sheridan were to him a constant inspiration. Intensely interested in Irish archaeology, he was a mine of information on place-names and other points of interest in his native land, which he knew from end to end as few indeed know it. Outside his professional work he was a daring and experienced yachtsman, and nothing gave him more pleasure than to leave his work behind for a month or so in the summer and sail away in one of the many boats he owned to explore the Scottish lochs, or the bays of the south and west coast of Ireland, or the sunny shores of France.

He was a member of the Council of the Royal College of Surgeons of Ireland, and for many years one of its examiners in surgery. Had he wished it, his many friends would have gladly elected him vice-president, but his modesty forbade his acceptance of the responsibilities of such an office. As a clinical teacher he was immensely popular with his students, and by his colleagues in the Menth Hospital and by his brother surgeons everywhere his memory will be held very dear.

F. B. WILLMER PHILLIPS, M.A., M.D., D.P.H.,  
Medical Officer of Health, Bedford; Consulting Physician,  
Bedford County Hospital.

WE regret to announce the death, which took place suddenly on March 23rd, of Dr. Willmer Phillips, medical officer of health for Bedford since 1905, and honorary consulting physician to the Bedford County Hospital.

Francis Barclay Willmer Phillips was born at Brighton in 1853, and entered as an undergraduate at Balliol College while Jowett was Master. He received his medical education at Guy's Hospital, and obtained the diploma M.R.C.S.Eng. in 1883, graduating M.A., M.B.Oxon. and B.Sc.Lond. two years later, and proceeding to the degree of M.D.Oxon. in 1889. In 1902 he obtained the D.P.H.Camb. Soon after qualifying he successively held appointments as resident obstetric surgeon at Guy's Hospital, assistant medical officer at the Eastern Smallpox and Fever Hospital, London, and as resident clinical assistant at the East London Hospital for Children; and about forty years ago commenced practice in Bedford, taking a prominent part in the evolution of the County Hospital there.

In 1905 he succeeded the late Dr. C. E. Prior as medical officer of health, and in 1914 received a full-time appointment in that office, with the additional duties of medical officer of schools and police surgeon. Later he became also medical officer of the infant welfare centre and medical superintendent of the isolation hospital. During the war, when there was a very large concentration of

troops at Bedford, he acted in close co-operation with the military authorities, served as an officer in the local volunteer training corps, and acted as medical officer to Bedford Prison during the absence of the holder of that post.

In the affairs of his profession Dr. Phillips played a considerable part. He was a member of the Royal Sanitary Institute and a Fellow of the Royal Institute of Public Health, and in the British Medical Association served as a member of the South Midlands Branch Council in the period 1896-97. His main interests otherwise were scientific and cultural; he was a keen classical scholar, and at the same time was devoted throughout his life to mathematical and biological studies, yet found opportunities in his later years to extend his knowledge in the fields of palaeontology and Russian literature. For many years he was associated with the Mathematical Association, the London Mathematical Society, and the Bedford Arts Club. The interment was at Hove. At a funeral service held earlier in St. Paul's Church, Bedford, there were present the Mayor and Corporation in state, representatives of almost every civic department and of many other organizations, and a large number of members of the medical profession, the British Medical Association being represented by Dr. E. R. Fasnacht.

#### CHISHOLM WILLIAMS, F.R.C.S.Ed.,

Formerly Electrotherapist, West London Hospital.

WE regret to announce the death, which took place suddenly at Finchley on April 10th, of Mr. Chisholm Williams, one of the earliest in this country to foresee and develop the medical uses of x rays, and one who, like many of those pioneers, suffered gravely from the effects of handling this then dangerous medium. George Chisholm Waldemar Williams began his professional career as a student at St. Thomas's Hospital, and obtained the diplomas L.S.A. in 1891 and M.R.C.S., L.R.C.P. in 1892. In 1898 he obtained the F.R.C.S.Ed. From his earliest days as a practitioner he was keenly interested in the application of electricity to medical practice, and devoted his spare time to experimental work. In 1895, seven weeks after Professor Roentgen had announced the discovery of the rays which were named after him at the time, Chisholm Williams succeeded in repeating the original experiments, and in making an x-ray photograph of his own fingers. Thereafter his devotion to the development of this discovery was unbroken, and he gave particular attention to the employment of the rays in the treatment of tuberculosis and cancer with a considerable degree of success. He was appointed surgeon to the City Orthopaedic Hospital, London, in 1894, and gave his services to that institution for some fourteen years. From 1903 to 1908 he was in charge of the x-ray department of the West London Hospital, and lecturer in radiology to the West London Post-Graduate College. In 1906 he joined the staff of St. John's Hospital for Skin Diseases.

From 1916 to 1919 he served with the R.A.M.C. in the rank of captain as electrotherapist to the Eastern Command Depot. It was at this period that the evil effects of the years of exposure to x rays, at a time when neither the need for nor the means of protection were known, became fully apparent. The condition of his hands had been severely aggravated by contact with septic cases during his war service, and a prolonged series of operations became necessary; after years of suffering the whole of one hand and two fingers of the other were amputated. As a result he was forced gradually to relinquish all active work. It was only last year that his services to science and his sufferings in its cause obtained recognition. In June, 1927, he received from the hands of the Duke of Connaught, at the prize-giving ceremony in connexion with the St. Thomas's Hospital Medical School, the bronze medallion of the Carnegie Hero Fund, the highest award of that body, given "for heroic endeavour to save human life," together with a cheque for the first instalment of a pension awarded him by the Fund. A few weeks later he was granted a Civil List pension in recognition of his self-sacrificing and devoted services in the application of x rays to the diagnosis and treatment of disease.

## THE LATE DR. A. E. NORBURN.

A COLLEAGUE sends us some further personal details about the late Dr. Albert Edward Norburn of Bath, of whom a short obituary notice appeared on December 17th, 1927. After graduating, Dr. Norburn acted as surgeon in the Union Steamship Company, and the large number of voyages he made between this country and South Africa proved of great benefit to his health; he secured many life-long friends, and his clear judgement and strong personality won for him the confidence of all. When he settled later in Bath he quickly established a large practice. His numerous activities then and during the war told adversely upon his health, and he was several times obliged to take long periods of rest. Mention has previously been made of his services to the Bath and Bristol Division; it will also be recalled that in connexion with the Annual Meeting at Bath in 1925 he was closely concerned in the work of preparing and arranging the admirable *Book of Bath*, written specially for that meeting. Besides taking a prominent part in this editorial work he contributed the chapters on "Present-day Bath" and "Later ecclesiastical history." The book was considered one of the best and most complete of its kind ever issued. Last autumn Dr. Norburn went on a visit to Italy, and appeared to have benefited much in health, but a fortnight after his return home he became ill with appendicitis and died early in December. The large attendance at the funeral service testified to the esteem in which he was held by his colleagues, patients, and friends. Dr. Norburn was unmarried.

Dr. RICHARD WILSON MULLOCK, who died in a nursing home at Norwich on March 23rd, in his fifty-third year, spent the greater part of his professional life at Southwold, Suffolk, where he was one of the best known among local practitioners. He received his medical education at Trinity College, Dublin, graduating M.B., B.Ch., B.A.O. in 1900, and proceeding M.D. in 1902. After obtaining his first degree he took part in the war in South Africa, serving as civil surgeon with the Royal West Kent Regiment. Subsequently he commenced practice in Southwold, where he was an active worker in connexion with the local hospitals. He was honorary medical officer to Southwold Cottage Hospital, medical officer to St. Felix School, honorary medical referee to the British Hospital for Incurables, Streatham, and held also a number of other appointments. The work of the British Red Cross attracted him, and he devoted much time and energy, as commandant of the Southwold V.A.D., to its activities. During the war, in addition to maintaining his instructional work with the V.A.D., he acted as chief medical officer at a temporary hospital established at Henham Hall, and to the heavy strain imposed upon him by these labours, added to the work of his practice and at the civil hospital, is attributed the illness which ultimately caused his death. Dr. Mullock was a member of the Medical Officers of Schools Association and of the British Medical Association. In the latter body he served as chairman of the North Suffolk Division in 1922, and was president-elect of the Suffolk Branch when he died. His widespread professional activities did not leave much time for other public affairs. He was for three years a member of Southwold Town Council, being elected in 1905, but on completing his term of office did not seek re-election. In Freemasonry he took a considerable interest. During recent years shooting was his chief recreation, but in his student days he was a keen oarsman and rowed for his college. Dr. F. W. BURTON-FANNING writes: Suffolk has again sustained an irreparable loss in the death of Dr. Richard Mullock of Southwold. Four years ago he had a severe attack of pneumonia, and although he returned to full work, it is probable that his health was never wholly restored. Two months ago he was found to be suffering from a hopeless malady, but he continued to work until he was forced to give in. He had won a remarkable position for himself in the district, and his large practice allowed him little rest. But, perhaps his best work was done at the Southwold Cottage Hospital. To serve this institution he had trained himself in operative surgery and in

radiology, and for many years his beds were kept full with patients sent for operation from the surrounding districts. He devoted himself heart and soul to the hospital, and its welfare was his chief hobby. Dr. Mullock was not passed fit for service abroad during the late war, but no one could have done more useful work than he did as chief medical officer to Henham Hall Hospital and as commandant of the Red Cross branch. The town of Southwold gave evidence at his funeral of the estimation in which he was held both as a friend and as a doctor. His grave in the cemetery is overlooked by the hospital, where he has left such a blank. Equally loved by his patients and by his colleagues, he was to have been president of the Suffolk Branch of the British Medical Association this summer, and he had busied himself with preparations for the meeting at Southwold. He leaves a widow and two sons and a daughter, for whom the greatest sympathy is felt.

Dr. CAVENDISH FLETCHER, who died on March 3rd, at the age of 45, obtained his medical education at the Westminster Hospital, graduating M.B., B.S.Lond. in 1906, and obtaining the diplomas M.R.C.S., L.R.C.P. in the same year. After qualifying he served for a time as house-physician at the Westminster Hospital, and later as assistant medical officer at the County Asylum at Leek. Subsequently he was appointed resident pathologist at the Royal Southern Hospital, Liverpool, so beginning that work in connexion with clinical pathology with which his name is most closely associated. In 1908 he joined the staff of the Laboratories of Pathology and Public Health in Harlow Street, and for the past eight years was director of that institution. He was also honorary pathologist to the King Edward Memorial Hospital, Baling. A colleague writes: By the death of Cavendish Fletcher clinical pathology has lost one of its ablest exponents. Engrossed in its pursuit, his sole preoccupation was with its advancement and with the perfecting of its technique. While a thorough master of all the present manifold ramifications of pathology he excelled especially as a morbid histologist, and his verdict on the interpretation of histological features was seldom falsified by the subsequent history of the patient. Much of the intense labour which he devoted to technical problems will never be known to the world, but those whose privilege it was to have him as a colleague and co-worker gained immense help from him. He leaves a widow and one son and one daughter, with whom much sympathy is felt.

Dr. JOHN ARCHIBALD CAMPBELL, who died in Glasgow on April 6th, was a native of Inverness-shire, but spent the greater part of his life in Glasgow, where he received his medical education at the Anderson College of Medicine, obtaining in 1900 the diplomas L.R.C.P., L.R.C.S.Ed., and L.R.F.P.S.Glas. Throughout his professional career he devoted himself to teaching and to bacteriology, and for nearly thirty years was connect Royal Infirmary. Until 1914 he was assistant bacteriologist and in that year he was appointed bacteriologist, a position he held at the time of his death. He was also lecturer on bacteriology in St. Mungo's College. At an earlier period he served on the staff of the Anderson College of Medicine, where he was for ten years, as senior demonstrator in anatomy, associated with the late Professor A. M. Buchanan, and for a time he was pathologist to the Ministry of Pensions Hospital at Bellahouston. He acted in a consultative capacity for a number of local authorities in the West of Scotland. Dr. Campbell, who was regarded as one of the pioneers in the use of vaccines, was a member of the Glasgow Medico-Chirurgical Society. A former colleague, Dr. ELIZABETH F. BUTLER, writes: As one who for many years worked with Dr. Campbell in the bacteriological laboratory of the Glasgow Royal Infirmary, I should like to testify to one aspect of his character and activities which I had exceptional opportunities for observing. I refer to his eager willingness to give his time, his labour, and his kindly consideration to all in need who came to claim them. It might be a student going up for

an examination; a doctor in difficulty over a case, a penniless invalid wanting a vaccine, a "rusty" practitioner from the wilds requiring to "brush up" his bacteriology—to each and all he gave his time, his thought, his work, with an air of cheerfulness which made it utterly impossible for the recipient to suspect that he was trespassing on another's magnanimity. There must be many to-day in the four corners of the earth who ponder these things with feelings of very grateful recollection.

Dr. ALFRED THOMAS TUCKER WISE, who died suddenly in a London nursing home on March 23rd, was born in 1847 and spent his early manhood in the Royal Navy, from which he retired in 1871 to enter the medical profession, beginning his studies at St. Mary's Hospital, London, and pursuing them later in Brussels and Geneva. In 1876 he obtained the diploma M.R.C.S.Eng. and graduated M.D.Brussels; a year later he obtained the L.R.C.P.Lond., and in 1891 the Swiss Federal Diploma in Medicine. Soon after qualifying he held resident appointments at St. Mary's Hospital, and was in practice for a short time in London. The development of a keen interest in tuberculosis and its treatment, however, led him to undertake specialized work in Switzerland, and after spending some time in the Engadine he settled down in practice in Montreux, where he remained for many years. During the war he was medical superintendent of the Devon County Sanatorium, Hawksmoor, South Devon, and afterwards he retired from active work. At one time he served for a period as visiting physician to the Infirmary for Consumption, Margaret Street, London. He was for many years a member of the British Medical Association. On retiring Dr. Wise took up his residence at Strete, near Dartmouth, spending the winters in Montreux, where, two years ago, he had a paralytic stroke from which he never fully recovered.

Dr. THOMAS AUGUSTUS DAVIDSON, who died in a nursing home in Belfast on March 28th, as the result of injuries received in a tramcar accident, was one of the best known medical practitioners in the city. He obtained the diplomas L.R.C.P., L.R.C.S.Ed., and L.R.F.P.S.Glasg. in 1887, and soon afterwards commenced practice in Belfast, where, apart from the interruption caused by the war, he spent the remainder of his life, taking a considerable part in professional affairs, notably in connexion with health insurance. Although well over military age he volunteered for service during the great war, and after acting as a civilian medical officer in Belfast received a commission as captain in the R.A.M.C., holding various appointments in Liverpool and being for a time in charge of the military hospital at Seaforth. On demobilization in 1919 he resumed practice in Belfast, and also served as a medical referee under the Ministry of Pensions. In addition to his professional activities Dr. Davidson had a keen interest in social and sporting affairs. He had travelled extensively on the Continent and in the Mediterranean, and was a keen student of languages; he took considerable interest also in Masonry. As a young man he gained prominence as a sprinter and as a racing cyclist; in his later years he was a keen motorist. Deep sympathy is felt for Dr. Davidson's two sisters, who were his constant companions.

Major CECIL HENRY ELMES, C.B.E., V.D., died of double pneumonia in Sunny Bank Hospital, Cannes, on March 26th, aged 55. He was educated at Edinburgh, where he graduated as M.B. and Ch.B. in 1900. Immediately after he served as a civil surgeon in the South African war. After practising at Tynbridge Wells for a time he went to Calcutta, where he was surgeon to the Royal Calcutta Turf Club, and also to the Calcutta Scottish, a volunteer regiment. During the war he entered Government service, and after serving as residency surgeon in Kashino in 1916-17, was appointed port health officer of Calcutta, a post which he held till his retirement in 1923. He then settled at Cannes, where he went in for yachting. In 1907 he married Katherine Tyson, who survives him.

The following well-known foreign medical men have recently died: Dr. K. V. HOON, professor of ophthalmology at Budapest, aged 68; Dr. JOSÉ MORENO, professor of therapeutics at Buenos Aires; Dr. LEONOLDO RIZZO, professor of clinical surgery at Naples; Dr. RICARDO BOTRY, an eminent oto-rhino-laryngologist, of Barcelona, aged 78; Professor CARLO FREDERL, director of the Instituto of Medical Pathology at Pisa, aged 76; Dr. MIRANDE, editor of the *Journal de Médecine et de Chirurgie Pratiques*; Dr. A. ANTIEAUME, secretary of the French Medico-Legal Society and author of a work on kleptomania and numerous other subjects connected with psychiatry and medical jurisprudence; and Dr. AUGUST SZEKELY, professor of infectious diseases and director of the Pasteur Hospital at Budapest.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

DIPLOMAS IN PUBLIC HEALTH, HYGIENE, AND TROPICAL MEDICINE AND HYGIENE (Part I).—B. J. Aiwani, M. S. Batra, \*C. F. Brockington, Bertha M. Butters, R. C. Dineen, I. K. Gayid, Margaret A. Glas, N. Gupta, \*G. A. Mossli, Joan H. Morton, R. A. W. Proctor, Effie S. Stephen, J. N. Vasudeva, Donella A. F. Watsoo, Dorothy Watterson, P. C. Wickromosingho, \*K. C. Yeo.

\* Distinguished.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on April 12th, when the President, Sir Berkeley Moynihan, was in the chair.

The best thanks of the Council were given to Dr. William Hunter for presenting to the Museum his collection of specious illustrating diseases and disorders of blood-forming tissues.

#### Jacksonian Prize.

No award was made for the Jacksonian Prize for 1927. The subject for the Jacksonian Prize for 1929 is "The pathology, diagnosis, and surgical treatment of diseases of the salivary glands."

#### John Hunter Medal.

The John Hunter Medal in bronze, with the triennial prize of £50, was awarded to Mr. Victor Ewings Negus, M.S., F.R.C.S., for his investigations into the comparative anatomy and physiology of the larynx and the anatomy of the bronchi in their relation to surgery.

#### Election to Fellowship.

The following Members of twenty years' standing were elected to the Fellowship: Charles Thurstan Holland, Ch.M., and Lieut.-General Sir Matthew Henry Gregory Fell, K.C.B., C.M.G., Director-General A.M.S.

#### Primary Fellowship Examinations in Oversea Dominions.

A letter was read from Dr. Primrose reporting the approval by the Executive Committee of the Canadian Medical Association of the revised scheme for conducting Primary Fellowship Examinations in Canada, and conveying the thanks of the committee for the very efficient and generous provisions made.

#### Revised Scheme for Primary Fellowship Examination to be held in Canada.

1. The Canadian Medical Association to be appointed the authority in Canada representing the Royal College of Surgeons in connexion with the proposed examination, and to be responsible for the arrangements to be made in Canada to enable the examiners of the College to conduct the examination in that country.

2. The Council of the Royal College of Surgeons at Toronto at the end of the year to select the secretary of the examination, and to determine the number of eligible candidates to be examined by the College to warrant the holding of an examination in Canada.

3. Two examiners in anatomy and two examiners in physiology, who shall be present or past members of the Board of Examiners in Anatomy and Physiology for the Fellowship, to be sent by the College from England.

4. A professor of anatomy and a professor of physiology, or such other persons as may be nominated, to be appointed by the College from names submitted by the Canadian Medical Association to act as assessors to the examiners.

5. The examination, written and viva voce, of each candidate in each subject to be conducted by two English examiners and one Canadian assessor.

6. The Canadian Medical Association to be invited to appoint suitable persons to act as assessors to the examiners in Canada, and the viva voce examination as soon after as convenient.

7. The examination to be held by the Board of Examiners in Anatomy and Physiology for the Fellowship at the Royal College of Surgeons in England, on the arrival of the examiners in Canada, and the viva voce examination as soon after as convenient.

8. The results of the examination to be determined and announced by the Board of Examiners in Anatomy and Physiology for the Fellowship at the Royal College of Surgeons in England, in such other way as may be thought desirable.

Paragraph 11 recites the ordinary regulations for the examination. A letter was read from Mr. A. L. Kenny, honorary secretary and treasurer of the College of Surgeons of Australasia (which includes

New Zealand), reporting that the Council of the College of Surgeons of Australasia most strongly approve and most earnestly hope to have put into practice at the earliest possible moment the proposal to provide for the Primary Examination for the Fellowship of the Royal College of Surgeons of England being held in States of the Commonwealth of Australia and in the Dominion of New Zealand, and stating that any assistance it may be in the power of their College to give in furtherance of that proposal will be most fully and willingly given. The matter was referred to a committee for consideration.

#### Hallett Prize.

The Council being desirous of showing appreciation of the services of Sir Frederic G. Hallett, O.B.E., in connexion with the examinations for the Fellowship and the Licence in Dental Surgery from 1877 to 1927, and Sir F. Hallett having expressed a wish that the personal gift which it was proposed to make to him should take the form of the endowment of a prize to bear his name, it was agreed that stock be purchased by the Treasurers of the College on behalf of Sir F. Hallett, and that they be authorized to reinvest the fund at any time if thought desirable; and that the interest from the fund so established be expended on a prize called the Hallett Prize, to be awarded under such regulations as the Council may from time to time determine.

#### Regulations.

The Hallett Prize shall be open to candidates admitted for the first time to the primary examination in anatomy and physiology for the Fellowship conducted by the Board of Examiners in this country.

The prize at each examination shall consist of a sum of five guineas with a certificate of the award of the prize.

The prize shall be awarded to the eligible candidate, if any, obtaining the highest marks, who shall have reached a standard considered by the examiners sufficiently high to justify the award of the prize.

If two or more candidates are found to have reached the required standard and to have been allotted the same number of marks, the highest obtained by any eligible candidate, it shall be open to the examiners to take such steps as they may think desirable to enable them to adjudicate in the matter.

#### ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the President and Fellows, held on April 13th, the following members nominated on January 5th—Robert Wallace Nesbitt, M.B., and O'Donel Thoruley Dodwell Browne, M.B.—were duly elected Fellows of the College.

Frederick John Ryan, L.R.C.P. and S.T., was stated to have completed the examination for the Diploma in Public Health of the Royal College.

The following candidates, having passed the Final Conjoint Examination in Medicine, Surgery, and Midwifery, were formally admitted by the President to the Licences in Medicine and Midwifery of the College: G. F. A. Condon, P. Daly, E. P. Mahood, F. L. G. Malone, R. J. McCloskey, J. F. Power, P. B. Walsh.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons reassembled on April 17th, when the Army and Air Force Annual Bill was passed through committee and read a third time after a debate on the retention of the death penalty for cowardice. On April 18th the House went into committee on the Equal Franchise Bill. The Edinburgh Corporation Bill, which asks Parliament to grant that corporation further powers for dealing with venereal disease, was set down for second reading on April 19th. The Government had agreed not to put its Whips on in opposition to the bill, a course which had previously been threatened, but a group of members, as well as outside organizations, issued appeals to members of Parliament to oppose the measure. On the previous day the Conservative Health and Housing Committee was summoned to hear the bill expounded by Sir Patrick Ford, an Edinburgh member.

#### Venereal Disease Clinics in Scotland.

On April 17th Sir J. GUMOUR, replying to Mr. Buchanan, said that the number of towns in Scotland with a census population of 10,000 or over and without a public clinic for dealing with venereal diseases was twenty-six, of which seven had a population of 20,000 or over. These burghs, in order of population, were: Clydebank, Falkirk, Airdrie, Rutherglen, Dumbarton, Port Glasgow, Inverness, Musselburgh, Hawick, Renfrew, Saltcoats, Peterhead, Galashiels, Johnstone, Alloa, Kirkcaldy, Barhead, Montrose, Buckhaven, Methil, and Innerleven, Rothesay, Dunoon, Cowdenbeath, Lochgelly, Fraserburgh, Boness, and Gourock. In three of these burghs—Falkirk, Inverness, and Rutherglen—provision for a venereal disease clinic was in course of being made, or under active consideration. Four of these burghs—Airdrie, Port Glasgow, Musselburgh, and Gourock—were so conveniently situated for the clinics of adjacent larger towns as not to require independent provision. The remaining nineteen burghs were served to a greater or a less extent by the nearest available clinics of other towns. In eleven of these burghs the Scottish Board of Health had not thought the question of providing a local clinic to be sufficiently urgent to call for pressure by them upon the local authorities, having regard to the facilities available in neighbouring towns. In the case of the remaining eight burghs—Clydebank, Dumbarton, Hawick and Galashiels, Peterhead and Fraserburgh, Saltcoats, and Kirkcaldy—the question

of establishing a burgh clinic or a joint clinic had been considered by the responsible local authority, and remained open. The development of the schemes in all areas was being carefully watched and reviewed by the Board.

#### Tetra-ethyl Lead in Motor Spirit.

On April 17th the House of Commons considered the Petroleum (Amendment) Bill on the report stage. Clause 4 of this bill authorizes the making of regulations concerning classes of petroleum likely to be dangerous or injurious to health. To this clause Mr. HANNE moved an amendment giving the Home Secretary power to prohibit the sale or use of petroleum spirit which he might, by order, declare to be so dangerous or injurious to health that precautions for the protection of persons employed or engaged in handling or using such petroleum spirit were impracticable. He said that the amendment referred to tetra-ethyl lead in petrol.

Sir W. JOYNSON-HICKS said he would accept the amendment. Tetra-ethyl lead in petrol was now the subject of an inquiry, and if the Home Secretary should, as a result, declare that this particular spirit was injurious to health, the amendment would usefully come in.

The amendment was agreed to. The report stage of the bill was completed, and the bill was read a third time.

A copy of the report of the American Commission on the use of tetra-ethyl lead in motor spirit will be placed in the library of the House of Commons.

#### Pensions.

Answering Dr. Drummond Shiels, on April 3rd, Major TAYNOR said he was not aware of deep resentment among panel practitioners at the scant courtesy with which their certificates and opinions were regarded by the Ministry of Pensions. It was certainly incorrect to say that the supposed reduction in the necessity for hospital accommodation in Scotland was due to the fact that many ex-service men were being refused treatment which they required.

Major TAYNOR told Mr. Bowerman, on April 5th, that the closing of the Ministry of Pensions clinic at Camberwell was not contemplated. The clinic at Bulging Street, Westminster, had, however, special facilities for surgical treatment not available elsewhere, and in their own interests certain cases living in other parts of London were on occasion summoned to it.

**National Insurance: Mileage and Drug Costs.**—Answering questions put on April 4th by Sir Robert Thomas, Sir KINGSLEY WOOD said there was no special contribution per head among insured persons towards the cost of mileage and drugs. The amount available for meeting this cost was 3s. 3d. per insured person in each county, but as the total expenditure on mileage and drugs in Wales exceeded that amount, the Act authorized payment out of the National Health Insurance Fund (England) to the Welsh National Health Insurance Fund to meet the excess expenditure. It had never been considered necessary that the Association of Welsh Insurance Committees should be represented as such on the Medical and Pharmaceutical Committees, which were charged with apportioning among Insurance Committees the sums available to defray the cost of medical treatment and drugs in England and Wales. There were Welsh representatives on the committees.

**Eye Diseases in the Navy.**—Asked by Sir Robert Thomas to explain the fact that in 1922, of 1,726 invalided out of the navy, 336 were on account of diseases of the eye, Colonel HEADLAM said that 345 of these cases were due to congenital deformities—long sight, short sight, and astigmatism. Five men were invalided for defective colour vision, three for injuries, three for cataract, and the rest for chronic inflammatory or degenerative conditions. No special inquiry seemed necessary. It was in consequence of the more frequent and rigorous examinations after a man had joined the service that latent errors of vision were detected.

**Third Party Indemnity Insurance.**—On April 17th Mr. ATKINSON introduced a bill to provide for third party indemnity insurance. He said the bill provided that it should be the duty of an insurance company, in so far as they were liable for third party claims, to pay those claims direct to the injured person. The bill was read a first time.

#### Notes in Brief.

At the end of February, 1927, 102,864 houses were under construction in England and Wales, and 125,611 had been authorized but not started under the Acts of 1923 and 1924.

Mr. AMERY, replying to a question on April 17th, said that seventy-one cases of dysentery had occurred among the prisoners in the Sinarango Prison Camp, Malaita, and there had been eight deaths. Seven cases were still under treatment on April 2nd.

Sir KINGSLEY WOOD states that measures are being taken to prevent floods from the Thames in the county of London in accordance with the report of the recent committee.

Sir KINGSLEY WOOD informed Mr. Kelly, on April 17th, that inquiries were proceeding into the effects of artificial silk manufacture on the health of the people resident in the neighbourhood of such factories.

The reports of the Government Inspector of Mines for Cornwall show that the health conditions of Cornish tin mines are generally satisfactory and have improved of recent years. The health conditions at Cornish china clay works are good, and no cases of disease due to the conditions of employment have come to the notice of the inspector.

## The Services.

### INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Wednesday, June 20th, at 7.15 p.m., under the chairmanship of Major-General Sir R. Havelock Charles, Bt., G.C.V.O., K.C.S.I. Price of dinner tickets, 16s. 6d. to subscribers and £2 to non-subscribers. Further particulars may be obtained from the joint honorary secretary, Major Sir Thomas Carey Evans, M.C., I.M.S.(ret.), 31, Wimpole Street.

### AUXILIARY R.A.M.C. FUNDS.

THE annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 2.30 p.m. on April 27th, at 11, Chandos Street, Cavendish Square, W., when the annual report and financial statement for the year ended December 31st, 1927, will be presented, and the officers and committee for the current year elected.

### DEATHS IN THE SERVICES.

Lieut.-Colonel Andrew Watson Cook Young, I.M.S.(ret.), died in a nursing home at Aberdeen on February 7th, shortly before his fifty-second birthday and just a week after his retirement was gazetted. He was born on February 25th, 1876, and educated at Aberdeen, where he graduated as M.B. and Ch.B. in 1898, and also took the D.P.H. in 1899. In 1906 he took the London Diploma in Tropical Medicine, with distinction. Entering the I.M.S. as lieutenant on January 29th, 1901, he got a brevet lieutenant-colonelcy for his services in the war on June 3rd, 1916, and became substantive lieutenant-colonel on July 29th, 1920, retiring on January 29th last. All his service was spent in military employ, except for a few years before the war, when he was medical officer of health for New Delhi. He served in the Tibet campaign of 1903-4, when he took part in the operations round Gyantse, and in the march to Lhasa, was severely wounded, and received the medal with a clasp. This wound was received from the sword of a lama while Young was assisting a brother officer. It was a head wound, which nearly killed him, and for it he received a permanent wound pension. In the recent great war he served in Russia in 1914, Gallipoli 1915, Egypt and Mesopotamia 1916-17, was mentioned in dispatches in the *London Gazette* of October 19th, 1916, and gained a brevet lieutenant-colonelcy. Young was a well-known sportsman, in his earlier years a keen polo player, and since the war had gone in for racing, at which he had been successful in winning many trophies, notably the blue riband of military racing, the Lucknow Army Cup, in 1919. He was a fine type of the now extinct regimental medical officer, popular with both officers and men.

Captain William Haig Ferguson, M.C., R.A.M.C., died in a nursing home in Edinburgh on March 5th, aged 37. He was the elder son of Dr. J. Haig Ferguson of Edinburgh, his maternal grandfather being the famous Edinburgh surgeon the late Sir Patrick Heron Watson. He was born on January 11th, 1891, and educated at Cambridge, where he took the degree of B.A. in 1913, and at Edinburgh, where he graduated M.B. and Ch.B. in 1916. Immediately afterwards he took a commission in the Special Reserve of the R.A.M.C., and on April 3rd, 1916, became lieutenant in the R.A.M.C. He was promoted to temporary captain on June 1st, 1918, and confirmed in that rank from October 3rd, 1919. He served in the recent great war, was mentioned in dispatches in the *London Gazette* of January 12th, 1918, and received the Military Cross on September 16th, 1918.

Surgeon Lieut.-Colonel Alexander Minto, R.A.M.C.(ret.), died in London on January 3rd, a few days before his 85th birthday. He was born at Kennethmont on January 13th, 1843, and educated at Aberdeen, where he graduated as M.B. and Ch.B. in 1864. Entering the army as assistant surgeon on March 31st, 1864, he became surgeon major after twelve years' service, and retired on July 16th, 1890. He served in the Ashanti campaign of 1873-74, and in the Afghan war of 1878-80, receiving the medals for these two campaigns. His surname was originally Minty; he changed it by deed poll to Minto in 1872. In the old regimental days he served as assistant surgeon in the 90th Foot, now the 2nd Battalion of the Scottish Rifles, and in the Rifle Brigade.

Surgeon Commander John St. John Murphy, R.N.(ret.), of Bournemouth, died at Cairo of pneumonia on February 22nd. He was educated at Queen's College, Cork, and in the Edinburgh Extramural School, and took the Scottish triple qualification in 1897. After filling the posts of resident surgeon of Cork North Infirmary and of assistant medical officer at the West Riding Asylum, Wakefield, he entered the navy as surgeon, became surgeon commander on February 26th, 1904, and retired after the war.

## Medical News.

THE annual conversazione of the West London Medico-Chirurgical Society will be held at the Kensington Town Hall at 8 p.m. on Friday, June 15th. At 8.30 o'clock the Cavendish Lecture will be given by Dr. Reilher of Lyons on "The thornpoutic, preventive, and social value of heliotherapy in surgical tuberculosis."

THE next social evening of the Royal Society of Medicine has been arranged for Monday, May 7th, at 1, Wimpole Street. The guests will be received by the President and Lady Berry at 8.30 o'clock, and at 9.15 Mr. P. B. Tustin will give an illustrated address entitled "Milk—from cow to consumer."

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, Cavendish Square, W., on Thursday, April 26th, at 8.30 p.m., a paper will be read by Dr. John Glinister, jun., on hair, considered medico-legally, which will be followed by a discussion. The meeting on May 24th will take the form of an exhibition of specimens of medico-legal (not solely pathological) interest.

AT the meeting of the Illuminating Engineering Society to be held in the lecture theatre of the Home Office Industrial Museum (Horseferry Road, Westminster, S.W.) on Tuesday, April 24th, an informal discussion on "Daylight, artificial light, and artificial daylight: their merits and drawbacks," will begin at 6.30 p.m. Copies of the introductory paper may be obtained from the honorary secretary, Mr. J. S. Dow, 32, Victoria Street, S.W.1.

AN announcement appears in our advertisement pages of a course of lectures on pathological research in its relation to medicine, to be given at the Institute of Pathology and Research, St. Mary's Hospital, London. The course opens with a lecture by Sir Almonroth Wright, principal of the Institute, on April 26th, and closes on June 14th. The lectures are free to members of the profession and medical students.

A SESSIONAL meeting of the Royal Sanitary Institute will be held in the Guildhall, Worcester, on Friday and Saturday, April 27th and 28th. On the first day the chair will be taken at 4 p.m. by Professor A. Bostock Hill, when there will be a discussion on river pollution, followed by a second discussion, to be introduced by Dr. Mabyn Wood, on infant mortality in Worcester from 1895 to 1925. On the second day, after a discussion on the Worcester activated sludge plant, a visit will be made to the sewage works. At a further sessional meeting, to be held at the Guildhall, Preston, on Saturday, May 5th, a discussion will be opened on the present position of the milk supply, by Professor F. E. Wynne. The chair will be taken at 10 a.m. by Dr. R. Veitch Clark. In the afternoon visits will be made to several points of interest, including the new tuberculosis hospital, in the neighbourhood.

THE Fellowship of Medicine and Post-graduate Medical Association announces that in addition to a number of special courses already in progress a special course at the Maudsley Hospital will begin on April 30th and continue for one month; it will consist of lectures and clinical instruction in psychological medicine. Full particulars may be obtained from the secretary, Fellowship of Medicine, 1, Wimpole Street, W.1, who will also provide information concerning the general course of work, which continues throughout the year, and consists of attendance at the ordinary practice of some forty or fifty London hospitals associated with the Fellowship.

THE Royal Institute of Public Health has made arrangements for a post-graduate course of lectures on judicial evidence, forensic medicine and toxicology, medico-legal pathology, and crime and insanity to be given in London during May, June, and July. The various subjects may be taken separately or as a whole. Further particulars can be obtained from the Institute, 37, Russell Square, W.C.1.

SIR JOHN BLAND-SUTTON, Bt., presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on April 16th. The Council recorded its profound regret at the death of its chairman, Lord Cave. On the recommendation of the Scientific Advisory Committee the Council approved the following grants: £200 for one year to Dr. Louis Cassidy, to be applied through the new National Cancer Campaign (Ireland); £300 for one year to Mr. Harold Burrows, working at the Cancer Hospital, London; £300 to Mr. C. F. W. Illingworth for one year for work to be carried out at Edinburgh University, and £1,000 for the ensuing year for work to be carried out under the supervision of Mr. F. C. Pybus, at Newcastle-on-Tyne. On the recommendation of the Executive Committee the Council also granted a sum of £400 to St. Mark's Hospital, City Road, and £100 to the Medical Society of London towards expenses incurred in the preparation and publication of statistical investigations. The Council received reports from the various committees in

charge of the preparations for the International Conference on Cancer, which, as announced in our last issue (p. 640), is to be held next July in London. Already forty acceptances have been received from foreign representatives, and over one hundred delegates have been nominated by universities, medical schools, and scientific and medical societies of the British Isles and the Dominions overseas.

THE Management Committee of King Edward's Hospital Fund for London, acting on behalf of the General Council of the Fund, have passed a resolution expressing deep regret at the death of Lord Cave. In paying tribute to his many services to the voluntary hospitals the resolution recalls that he was chairman of the special committee of inquiry set up by the Minister of Health during the crisis of 1921, when many of the voluntary hospitals were threatened with bankruptcy.

SIR VIVIAN HENDERSON, M.P., Parliamentary Under Secretary to the Home Office, on March 25th discussed with a deputation from the Council of Industrial Medicine the projected Factories Bill. He gave an assurance that the points of detail raised would receive sympathetic consideration in drafting the measure, and stated that it was not the intention of the Home Office that medical officers connected with industrial undertakings should be excluded as such from becoming "appointed doctors" for the purposes of the Act, and that every encouragement would be given to the appointment of medical officers by individual firms for the general supervision of the health, safety, and welfare of their workers.

THE minutes of the evidence taken by the Royal Commission on Local Government are being published from time to time as the inquiry proceeds, and Part X, which has now appeared and which is obtainable from H.M. Stationery Office at 6s. net, contains evidence given by a number of witnesses on behalf of the Rural District Councils Association and the County Councils Association. The Commission is now engaged on the second part of its inquiry, the task being to investigate the relations between the various types of local authority, and generally to make recommendations as to their constitution, areas, and functions. In its first report the Commission dealt with the constitution and extension of county boroughs.

THE Hospital Saving Association, which now has 425,000 subscribing members, has inaugurated a campaign to increase its membership to 500,000, and is inviting employers to assist by forming business or factory groups, while householders may arrange for domestic servants to join as individual members. The association does not ask for contributions from employers, funds being obtained by a small levy on working-class subscribers, and in return it meets any hospital charges which its members or their dependants may be called upon to pay in respect of treatment. Particulars may be obtained from the chairman, Viscount Hambleden, 77, Cambridge Terrace, W.2.

UNDER the auspices of the Royal Institute of Public Health a tour for medical practitioners has been arranged from May 19th to 28th, the places to be visited being Paris, Vichy, and Aix-les-Bains, while extensions are possible to the sanatoriums of Switzerland and to the Italian Riviera. In each place important medical institutions will be visited: in Paris these include the Salpêtrière, the Hôpital de la Pitié, Laennec, Necker, the Val de Grâce medical military school, the Cochin Hospital, and the Faculty of Medicine of the University of Paris. Leading members of the medical profession in France will meet the party. Further information may be obtained from Dr. T. N. Kelynaek, 37, Russell Square, W.C.1.

MR. GEOFFREY KEYNES has prepared *A Bibliography of the Works of William Harvey*, with eight collotypes and numerous facsimiles in line. The volume will be published by the Cambridge University Press in a limited edition of 300 copies, to celebrate the tercentenary of the publication of Harvey's first and greatest work, *De Motu Cordis*.

UNDER the presidency of Professor Rossetti of Lausanne the first International Congress on Light, from the physical, biological, and therapeutical points of view, will be held at Lausanne and Leysin from September 4th to 7th; at the same time there will be celebrated the twenty-fifth anniversary of the special work in this connexion by Dr. Rollier. The subjects to be dealt with at the congress will be announced later, and further information may be obtained from Dr. G. Murray Levick, 73, Harley Street, W.1.

THE ninth international congress against alcoholism will be held at Antwerp from August 20th to 25th. Further information can be obtained from the World Prohibition Federation, Lawson House, 190, Vauxhall Bridge Road, S.W.1.

THE fourth congress of Oriental medical practitioners, under the patronage of the Government of Prussia, will be held at Prague on May 27th.

THE sixth conference of the International Union against Tuberculosis will be held in Rome from September 25th to 27th, 1928. The subjects of discussion will be: filterable elements of the tubercle virus, the diagnosis of infantile tuberculosis, and the organization of tuberculosis prophylaxis in rural districts. Conferences on special subjects will also be held.

THE tenth congress of the association of the French-speaking medical profession of North America will be held at Quebec, under the presidency of Dr. Dagneau, from September 5th to 7th, when there will be discussions on puerperal fever and diphtheria. The meeting will coincide with the celebration of the twenty-fifth anniversary of the foundation of the association.

THE Dutch Industrial Exhibition, which will be held at Rotterdam from June 1st to September 15th, will include a section of industrial pathology and hygiene, which has been organized by a committee under the presidency of Dr. Josephus Jitta. Further information can be obtained from Dr. J. Sanders, Heemradsingel 240, Rotterdam.

A COLLECTION of articles upon the physical and medical aspects of ultra-violet ray therapy appears in a supplement to *Nature* this week (April 21st). They include papers on the physical basis of light therapy, by Professor F. L. Hopwood; on the biological action of ultra-violet rays, by Professor Leonard Hill; on the physiological action of ultra-violet radiation, by Dr. W. Kerr Russell; on ultra-violet radiation for domestic use, by Professor S. Russ; and on medical aspects of "artificial sunlight" in private houses, by Dr. P. R. Peacock.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 3561, 3562, 3563, and 3564** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

## QUERIES AND ANSWERS.

### RADICAL CURE OF HERPES GENITALIS.

REPLYING to Dr. D. S. Pattanay's inquiry (April 14th, p. 650), "O. S." writes: Having been a sufferer in boyhood from a recurring herpes of the glands and prepuce, associated with a tight foreskin, the attacks being accompanied at times with herpes labialis and general symptoms, may I suggest that in addition to rigid cleanliness with a weak sulphur-lanolin ointment locally, investigation be made of the influence of a food factor in the causation? In my own case sugar invariably precipitated an attack.

### CONSERVATIVE TREATMENT OF ENLARGED TONSILS.

"A. B." asks for the formula of a paste or application used at intervals of two or three weeks by some laryngologists for reducing the size of chronic enlarged tonsils in adults who dread operation.

\* \* \* In a letter published in the *British Medical Journal* of September 17th, 1927 (p. 516), Sir James Dundas-Grant spoke favourably of an application consisting of iodine 5 grains, acetic ether (acid-free) 2 fluid drachms, and glycerin up to 1 ounce; the paint to be well shaken and brushed into the tonsils. The acetic ether appears to carry the iodine into the depths of the tonsillar

crypts. Sir James Dundas-Grant also referred to thymol water as a useful prophylactic gargle, and recommended the clearing away of caseous masses filling the tonsillar crypts by means of a fine dental syringe, with the point bent at a right angle, charged with hydrogen peroxide (equal parts of the ten volume solution and warm water).

#### PAROXYSMAL ORYZA.

"W. M. M.," in reply to "F. D. J.'s" question about the treatment of paroxysmal mucous nasal discharge, suggests the administration of calcium and parathyroid extract, or thyroid extract.

Dr. LINDLEY SEWELL (Manchester) offers the following recommendations: (1) A fruit and vegetable diet, including milk, eggs, meat, and fowl. (2) Taking some calcium preparation for a considerable time and with regularity. (3) Painting the middle turbinate and middle meatal region of the nose with 3 per cent. silver nitrate solution once a week for five or six times. (4) A change of residence to some seaside place, such as Weston-super-Mare or Grange, where mudflats are left at low tide. (5) A careful search for any possible source of irritation, such as fowls, feather beds or pillows, dogs, cats, new paint.

#### INCOME TAX.

##### Replacement of Car and Instruments, etc.

"W. T. C.," bought a Morris Cowley car in 1923 for £250 and in 1927 sold it for £40, buying a Morris Oxford car for £215. What claims should he make, and what is the position with regard to expenditure on books and instruments?

\* \* As regards the car he should claim obsolescence allowance, as a professional expense of the year 1927, as follows: £180 (or rather, the exact cost in 1927 of a Morris Cowley car of similar type to the one replaced) less £40, say £140; also depreciation allowance for 1927-28, £215 at 15 per cent. = £32. The position with regard to books and instruments is that expenditure on their replacement is admissible, but the cost of improvement, as compared with the original value of the old article, must be excluded. There is the further difficulty that until the old instrument or book is definitely "scrapped" the new one represents an addition and not a renewal; if the former is useless it is obviously advisable from the income tax standpoint to get rid of it altogether, and thereby avoid a possible objection to the claim.

##### Motor Car Transaction.

"G. W. M.," bought an 11-h.p. car in 1922 for £330 and sold it in January, 1927, for £65, when he bought a shop-coiled 14-h.p. car for £443. In the last two years he has had 15 per cent. on £40 depreciation allowance for the old car—say £12 in all.

\* \* Obsolescence allowance, £330-£65 = £265, as an expense of the year 1927. Depreciation allowance for 1927-28, 15 per cent. on £410 = £66.

#### LETTERS, NOTES, ETC.

##### LECTURERS ON SOCIAL HYGIENE.

Dr. A. H. HARKNESS (honorary medical secretary, British Social Hygiene Council) writes: Owing to the numerous calls the British Social Hygiene Council is in need of the services of additional medical men: (1) Those who would be willing to leave London and to undertake from three to ten days' lecturing with public health films in the provinces; (2) those with experience in popular speaking willing to address general industrial audiences on problems of social hygiene in London and the Home Counties area. Full particulars are given in an advertisement in this week's issue.

##### TREATMENT OF PNEUMONIA.

Dr. J. W. DUNCAN (Birmingham) refers to Dr. D. Hennessy's letter on the treatment of pneumonia by polyvalent antistreptococcal serum (March 31st, p. 572), and reports six cases, three of which were treated with antistreptococcal serum and vaccine and recovered, while the three other patients died. He adds that there is nothing sensational in the use of the serum; the temperature, as a rule, does not fall, but there is no crash at the crisis. His point is that injections of serum, followed by small doses of vaccines, seem to be very beneficial in these cases.

##### THE PULPLESS TOOTH.

Mr. A. P. BERTWISTLE writes: I thank you for your references (at p. 637 of the Journal) to my paper on "The role of dead and infected teeth in autogenous infections." There are, however, two pulpless teeth are the cause of 70 per cent. of I stated that the most important sign on clinching the jaws and on percussion, not "on eating."

##### STARTING POINTS FOR A TUBERCULOSIS CAMPAIGN.

Dr. GORDON TIPPETT (London, S.E.) suggests that as a preliminary to a general campaign to stamp out tuberculosis it is necessary to determine the following points: Is food infection by tubercle bacilli harmful, and, if so, why is it not prevented? Does not exposure of food lead to contamination by human tubercle bacilli? Is any case ever too early for treatment? Some further

lost (he says) is required to prove definitely the presence of living tubercle bacilli in the body. Some bacteriological procedure is necessary so as to make it clear whether the treatment has been successful or otherwise, since physical examination may be misleading. Dr. Tippet considers that such a criterion of cure is essential, because otherwise it is impossible to be sure that any form of treatment is effective. He adds that the examination of sputum for tubercle bacilli should only be undertaken by a bacteriologist, who should be a fully qualified medical practitioner, and should report on conditions other than the mere presence or absence of these bacilli.

##### SURVIVAL OF QUADRUPLETS.

Dr. KENNETH J. FRANKLIN (Pharmaceutical Laboratory, Oxford) writes: The following extract from Henley Register (Diocesan Transcripts) has been shown to me by Mr. C. R. Oldham of Oriel College, and, in view of the rarity of survival of quadruplets, I am sending it on to you. It may also suggest to the curious a possible source of further information on such subjects. The entry in the register is:

"Cath. Pnlocha, aged 36, died in childbed, with four children born alive, bur. 16 Feb. 1799."

##### FIVE GENERATIONS ATTENDED BY ONE DOCTOR.

Dr. L. J. HOOD (Melbourne, Australia) asks whether any other medical practitioner has had what he considers the unique experience of attending five generations in the one family. Dr. Hood writes: The great-great-grandmother is now aged 90, and has been a patient of mine for nine years. Her married daughter and granddaughter have both been under my care for some years. The great-granddaughter was married last year, and is now the mother of a bonny boy, both of whom I attended.

##### THE GORILLA AT HOME.

LIEUT.-COLONEL CLAYTON LANE, I.M.S. (ret.), referring to "Notes on the gorilla," a recent article in the *Proceedings of the Zoological Society* by Dr. Neville A. Dyce Sharp, West African Medical Service, writes: "The varied opportunities for adding to knowledge in unexpected ways which fall to officers in our medical services abroad is illustrated from West Africa. In the Mamfe division of the Cameroons the gorilla is hunted and eaten by man, and attacks man at sight. Not a few hunters owe their lives merely to the remote position of the gorilla's thumbs, so that from his uncertain grip a man may wriggle. Such unfortunate manners make it no light task to observe the creature's habits, but Dyce Sharp's information and observations warrant the following statements regarding gorillas and chimpanzees. In that locality the chimpanzee is a timid, monogamous, widely distributed herd animal, both sexes making small untidy holes, like storks' nests, 30 ft. to 50 ft. up in the trees. The gorilla is a fierce, polygamous, family animal, living on steep terraces 1,200 ft. to 5,000 ft. above sea-level, and together with his four to six wives and their children, and perhaps an elder son not yet thrust out to fend for himself, patrolling an area of twenty to forty square miles. The head of the family is not arboreal, but makes for himself, of stout bent saplings, branches, twigs, and leaves, a luxurious bed on the ground, perhaps 9 ft. across and 12 in. to 18 in. deep, as nearly resembling a spring mattress as the materials permit. It is said by the natives that the 'old man' allot to each wife her own tree fork, where she builds, as he does from material within arm's reach, a bed 3 ft. or 4 ft. in diameter. Dyce Sharp has repeatedly verified the fact that the head of the family, reclining at ease against the tree trunk adjacent to which his bed is built, can watch the arboreal nest of every wife. No bed is used for more than one night. The gorilla, though fond of grubs and caterpillars, is essentially a vegetarian, eating mainly the growing points and stems of a sugarcane-like sotaman, and that in prodigious quantity, as will be clear from the estimate that the amount of undigested faecal residue beside, but not on, the bed of a single male was estimated at 25 lb. to 30 lb. It is interesting to speculate on the feelings of a human being who daily lost the equivalent of 2 stone between bed and breakfast. The day's life, particularly for the head of the family, must be little else than a strenuous search for food, the making of a bed and of a toilet, and the perpetuation of the species. But this routine may be abruptly terminated by the violent irruption of a stranger—some new-grown male who purposes, through a grim and bloody fight, to appropriate the harem and feeding grounds of the gorilla in possession."

##### NEW LIGHTING LAWS FOR MOTORISTS.

FOR the convenience of motor owners and drivers the Automobile Association is issuing a booklet epitomizing the various changes in the law relating to lights on vehicles. In addition to the Road Transport Lighting Act, which comes into operation on April 22nd, there are certain changes which are to be the subject of regulations issued under that Act, and immediately these regulations are issued the A. A. booklet will be available, free of charge, to any motorist on application by postcard to the Secretary, Automobile Association, Faum House, New Coventry Street, W.1.

##### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 53, 56, 57, 58, and 59 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 54 and 55. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 136.

## An Address ON THE CAUSES OF THE DECLINE IN TUBERCULOSIS MORTALITY.\*

BY  
SIR ROBERT PHILIP, M.D., LL.D.,

PROFESSOR OF TUBERCULOSIS IN THE UNIVERSITY OF EDINBURGH;  
PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

LET me crave indulgence for the introduction of a brief personal reference which has bearing on the significance of our discussion to-day. While tuberculosis has been known from all times it has, during the past fifty years, assumed a new aspect. Throughout the latter period we have come to realize, as never before, what we are up against. It so happens that my medical history covers that period of fifty years almost to a day. During the first four years, as an undergraduate in medicine, one became familiar with the general helplessness and hopelessness of medicine in respect of tuberculous disease. Pathology had revealed much regarding the morbid anatomy of tubercle, but little regarding the natural history of the disease. Diagnosis was limited to pronounced cases; prognosis was, for the most part, pessimistic; and treatment empirical. Tuberculosis remained, as I ventured to call it in my graduation thesis, the opprobrium of medicine.

Although the old-time conception of its infective character had already received scientific confirmation in the seventies by the prolonged investigations of Villemin, it was in 1882-83 that bacteriology demonstrated, once for all, the causal organism. I remember vividly the repercussion of Koch's pronouncement. To those of us who were working in laboratory at the time it called for pause. Microscopical work on other lines was arrested in favour of a consideration of the new clinim.

### *Fresh Horizon.*

It was the coming of that event at that particular moment which determined the interest of a lifetime—an interest as fresh to-day as when it was kindled. Combined laboratory and clinical observation compelled one gradually to the conclusion that the attitude of medicine to tuberculosis was wrong. Attention had been concentrated on end-results, and these especially in the lung. The physician waited until the disease presented itself in aggravated form.

The basal fact of infection having been accepted, it seemed clear that the principles which governed the detection and control of other infections might be applied to tuberculosis, and, especially, that in place of waiting until the effects of the tubercle bacillus were eloquent—often evident to the man in the street—our aim should be to search for the earliest manifestations of infection and probe into conditions which conduced to grosser disease. It was study of the nature of the infection and of the essential cause of death in tuberculosis which led to the proposal for special centres of observation and the establishment, in 1887, of the tuberculosis dispensary.

The circumstances were thought-compelling. Why was the prognosis commonly so unfavourable? Why did most of the patients die? Why were the cases under treatment so largely those of advanced disease? What was the natural history of the disease? Why, and how, was the infection contracted of which those cases were the final fruit? Why was the disease undetected at the earlier stages? Answers to these questions were gradually evolved. It emerged that the advanced stage constituted but the last scene in the long drama of infection. It became evident that the earlier stages of infection must be sought for. The infection must be traced to its source and the commencing stigmata of disease determined. Observations on those lines led to the conception of tuberculosis as a household disease and, presently, to the systematic examination of the household group and of the home itself and other environmental conditions. Thus came to be instituted the examination of contacts and domiciliary visitation.

\* Introductory to a discussion at a meeting of the Society of Medical Officers of Health held at Bath, April 20th, 1928.

Gradually the problem extended. Tuberculous infection was seen to be widespread throughout civilized communities. For the most part it was contracted in childhood. Varying degree of resistance to the infection was offered by different individuals. The resultant of the infection depended on the amount of the infecting dose and its repetition, and on the resistance offered by the individual. The degree of resistance was influenced greatly by environment—interpreting that term in a wide sense—and to some extent by racial quality. In consequence of this the outward manifestations of the infection differed much in character and degree.

All this meant a revision of the medical outlook. Attention had to be directed: (1) towards the detection of the infection at the earliest possible moment; (2) towards detubercularization of the tubercularized individual as speedily and thoroughly as might be; (3) towards the elimination, or at least progressive lessening, of environmental conditions which fostered the advance of infection by lowering individual resistance; (4) towards securing sufficient duration of efficient treatment in presence of pronounced disease; (5) towards the limitation of the spread of infection from advanced cases.

### *Evolution of the Tuberculosis Scheme.*

In order to meet the different issues there evolved progressively the several elements in what is now described as the tuberculosis scheme, generally applied throughout the land. In so far as it has really met the issues and been efficiently handled the machinery has proved serviceable. If experience has shown that the quality and temper of the machine, as erected in different areas, have not always been equal, nor the standard of the personnel in charge, that is only what was to be expected.

### *Specialized Training.*

Time is improving both the machinery and the personnel. The purposes and hang of its different parts are becoming better understood; the training of the officers in charge is being progressively adapted to the needs. Thus, at the University of Edinburgh the undergraduate in medicine has a course of thirty meetings on tuberculosis. The course is practical and compulsory, and tuberculosis is included among the subjects for the final examination in medicine. Candidates for the Diploma in Public Health attend a further course of twenty meetings, and the subject forms part of the examination for the diploma.

The Departmental Committee on Tuberculosis recognized and enforced the need for special training and experience in dealing with the disease. It seems singularly inopportune that, just when the machinery is getting into motion throughout the country, the proposal has been made to replace the specialized staff by officers in the public health service who happen to have time, but may have little experience of or interest in the complex problems. The issues involved are critical. It is not good policy to swap horses in crossing the ford.

### *Decline of Mortality: Accelerating Drop.*

Turning to the subject more definitely before us to-day, the title of the discussion assumes that there has been a decline in mortality. One wonders whether the extent of the decline is quite realized. Judging by loose statements in the press, it is clear that there is need to emphasize its remarkable extent.

The graphs showing the decline in mortality from tuberculosis in Scotland from 1871 up to the present date tell their own story. The remarkable decline has been continuous throughout the period. This is, however, not all. Closer examination reveals that the rate of decline has been an accelerating one. This is evidenced by the sharp downward trend of the line of mortality. Had there been no increasing rate of drop throughout the period the downward trend of the curve would have been less steep. As the Registrar-General for England (Annual Report for 1920) says:

"Not only is the absolute fall (of mortality) greater, but, as compared with the lower level of mortality prevalent at the present day, the relative fall is very much greater than would have

resulted from an equal absolute fall at an earlier period, had it ever occurred.

"The uniformity of the average annual decrement of mortality represents an ever-increasing acceleration of the rate of fall, when measured in proportion to the total extent of mortality remaining."

The acceleration of the drop of the death rate of all tuberculosis for England and Scotland respectively is illustrated in Tables I and II. The numbers on the tables are five-yearly means, centring on the year selected. If, in the case of England, we compare successively the death rate of each of the years 1881, 1891, 1901, 1911, and 1921 with that of ten years before, the 1881 death rate in England shows a drop of 14 per cent., the 1891 death rate a drop of 15 per cent., the 1901 death rate a drop of 19 per cent., the 1911 death rate a drop of 21 per cent., and the 1921 death rate a drop of 20 per cent.

The corresponding figures for Scotland are: the 1881 death rate shows a drop of 17 per cent., that of 1891 a drop of 21 per cent., that of 1901 a drop of 9 per cent., that of 1911 a drop of 21 per cent., and that of 1921 a drop of 31 per cent.

The figures from Ireland (as shown in Table III) are similarly instructive.

#### *In Excess of Decline from Other Causes.*

All very well, says the critic; but the decline in tuberculosis mortality is in line with the drop in the general death rate, of which it is but part expression.

This is not so. The accelerating drop in the tuberculosis death rate exceeds greatly the drop in mortality from all diseases throughout the same period. The extent to which the decline in the death rate from tuberculosis (all tuberculosis, pulmonary tuberculosis) has exceeded that from all diseases is illustrated likewise in Tables I, II, and III.

If we take the last complete decennium, 1911-1921, the drop in the all tuberculosis death rate in Scotland (Table II) amounted to 31 per cent., and the drop in the pulmonary tuberculosis death rate to 27 per cent., as against a drop of 7 per cent. in the death rate from all diseases. Taking the entire period of fifty years, the death rate from tuberculosis was reduced by two-thirds, while that from all diseases was reduced by rather less

than one-half; or, viewed in another way (Table IV), while in 1871 the deaths from all tuberculosis constituted 16.8 per cent. of deaths from all diseases, in 1921 the deaths from all tuberculosis constituted only 9 per cent. of the deaths from all diseases. And, similarly, while in 1871 the deaths from pulmonary tuberculosis constituted 11.8 per cent. of deaths from all diseases, in 1921 they constituted only 6.2 per cent. of the deaths from all diseases.

The next point that occurs to one is, How does the decline in mortality from tuberculosis stand in relation to mortality from other groups of killing diseases? The facts are so well known to you that detailed statistics are unnecessary. Broadly speaking, if we compare (Table V, Scotland) the mortality of 1891 (mean of three years round 1891) with the mortality of 1921 (mean of three years round 1921), we find, that, of a total annual saving of life in respect of all causes of death of 557 per 100,000 of the population, the decline in tuberculosis mortality is responsible for a saving of 126. Compared with this, the group of heart diseases shows a negligible saving only, while kidney and vascular diseases show an actual increase of mortality, and cancer a marked increase.

The next point that occurs to one is, How does the decline in mortality from tuberculosis stand in relation to mortality from other groups of killing diseases? The facts are so well known to you that detailed statistics are unnecessary. Broadly speaking, if we compare (Table V, Scotland) the mortality of 1891 (mean of three years round 1891) with the mortality of 1921 (mean of three years round 1921), we find, that, of a total annual saving of life in respect of all causes of death of 557 per 100,000 of the population, the decline in tuberculosis mortality is responsible for a saving of 126. Compared with this, the group of heart diseases shows a negligible saving only, while kidney and vascular diseases show an actual increase of mortality, and cancer a marked increase.

#### *Not Uniform Throughout the World.*

A comparison of the mortality from tuberculosis in Great Britain with that of other countries is instructive. The mortality records in different lands vary much, and the decline in the death rate is correspondingly various. If we take Paris, as representing France, and Vienna, as representing Austria, attention is at once arrested by the high death rate from tuberculosis prevailing in these old centres of civilization. Incidentally, these high figures are illuminating in view of the suggestion frequently made that diminution in mortality from tuberculosis throughout the world is the result of an advancing immunization of civilized populations against the disease. In Paris prior to the war the death rate ran about 400 per 100,000, and in Vienna apparently about the same number. After the war France began to look into the matter, and during the past few years there has been gradually instituted an anti-

FIG. 1.—SCOTLAND.

#### *TUBERCULOSIS — DEATH RATES — 1871 to 1923.*

tuberculosis movement. In 1921 the death rate for Paris was 286 per 100,000. In 1920 the death rate for Vienna, where medical endeavour was much disorganized, was reported as 405 per 100,000.

Taking the several arrondissements (districts) of Paris, M. Henri Sellier, of the Office Public d'Hygiène Sociale du Département de la Seine (Rapport présenté au Conseil Général de la Seine, Décembre, 1927), indicates that considerable differences are beginning to show themselves in the mortality rates, and that these differences are referable to the differences in respect of antituberculosis activity.

The variation in death rate, and the amount of its recent decrease (or increase) in the several arrondissements is illustrated in the chart of Paris (p. 705) prepared by M. Marcel Moine, statistician to the Comité National.

A similar observation has been published by Professor Courmont in relation to the city of Lyons, where antituberculosis measures have been applied for some twenty years.

Of countries which hold a conspicuous place in respect of concerted effort against tuberculosis we may take as an example from Europe (apart from Great Britain) Denmark, and from outside Europe the United States.

In Denmark an intensive campaign has been maintained for some twenty-five years, with large contributions on the part of the Government. In 1801 the tuberculosis mortality of Denmark was 210 per 100,000, and in 1922 it was 95 per 100,000. Professor Knud Faber of Copenhagen, whose judgement is worthy of high consideration, states that at the present time Denmark has the lowest death rate from tuberculosis in Europe, and traces this decline to the highly concerted effort directed against the infection.

Taking New York as typical of American antituberculosis work, for the initiation of which the late Dr. Hermann Biggs was especially responsible; the figures are striking. Thus, in 1907, at the commencement of a special effort to

FIG. 2.—SCOTLAND.

TUBERCULOSIS—AGE DEATH RATES.

TABLE I.—ENGLAND AND WALES.

Deaths from All Causes, from Tuberculosis, and from Pulmonary Tuberculosis.

(Numbers are five-yearly means centring on the year named.)

Year.	All Causes.	Tuberculosis.		Pulmonary Tuberculosis.		
	Both Sexes.	Both Sexes.	Males.	Females.	Both Sexes.	Males.
<i>Number of Deaths.</i>

co-ordinate antituberculosis activities, more particularly by a combination of the institutions concerned with the dispensary control of tuberculosis, the tuberculosis death rate was 238 per 100,000. In 1921, notwithstanding an increase in population of a million and a half, the death rate from tuberculosis stood at 106 per 100,000.

From the cities and counties in Great Britain various illustrations might be cited. For the present purpose one will suffice. The administrative county of Lancaster, with

a population of nearly two million, has, by common agreement, one of the most comprehensive schemes, with whole-time consultant tuberculosis officers. The following table compares ten years pre-war, when there was no complete tuberculosis scheme, with nine years post-war, when the tuberculosis scheme was more developed.

Year.	Pulmonary Tuber- culosis Death Rate per 100,000 of Population.	Average Death Rate.	Year.	Pulmonary Tuber- culosis Death Rate per 100,000 of Population.	Average Death Rate.
Pre-war.			Post-war.

1912	85		1926	64	
1913	82		1927	61	
1914	87				

These examples might be multiplied. Enough has been cited to support the view that, where special anti-tuberculosis work is undertaken, results follow, and that, conversely, in proportion as a *laissez-faire* policy is pursued, little happens. Taking the map of the world, it seems fair to say that the more striking decline in mortality from tuberculosis is to be found in those countries where co-ordinated measures against tuberculosis have been continuously applied throughout a sufficiently prolonged period. Where there is no marked decline one may pretty surely predicate the absence or slackness of concerted effort.

A further interesting comparison is to be found between urban and rural districts. It is frequently stated that tuberculosis is a disease of cities and that country areas are relatively exempt. This is doubtless true for the most part. Referring to the point, however, a recent writer in the *American Review of Tuberculosis* (October, 1927, p. 535) says that, while it was true at the beginning of the century, "there is now evidence that in rural New York (State) the mortality from tuberculosis has since 1920 been in excess of the urban mortality, and that this excess has increased year by year"; and with reference to the same point, the editor of that review says, "We are justified in the assumption that the antituberculosis campaign, immeasurably better carried on in the cities, is beginning to tell, is therefore fundamentally sound and effective, and must be organized to more purpose in the

country." In keeping with this are the present high mortality rates recorded from the islands of Scotland in comparison with those of the country as a whole.

Interpretation of Decline: Contributory Factors.

The facts relating to the decline in mortality are very remarkable. How, then, are they to be interpreted? What has caused the decline? In seeking to formulate an answer, let me put it to you that it is likely that there have been numerous contributory factors. We shall all agree that every influence which has made for the physiological welfare of the community has played its part in the reduction of the tuberculosis death rate as of the general mortality rate.

There can be no doubt that the wave of awakened interest in sanitary matters, which commenced in Britain some eighty years ago and resulted in the appointment of the Royal Commission of 1869, was a primary factor of first importance. The report of that Commission in 1871, and the establishment of the Local Government Board, meant a practical awakening throughout the land. The powerful wash of the wave is well illustrated by the remarkable words of Lord Beaconsfield at Manchester in 1872: "After all, the first consideration of a Minister should be the health of the people." It is noteworthy that the great statesman looked beyond disease to the goal of health.

Another significant influence has been the general education of the people during the past fifty years. This has meant a wide diffusion of knowledge hitherto restricted to a limited portion of the community. Alongside of this we note the various movements for the betterment of housing and working conditions, the associated rise of the standard of living, better wages and better supplies, and the regulation of working hours, with greater facilities for regulated rest and open-air activity.

Among measures directed particularly towards the maintenance of health should be included the National Health Insurance Act and the medical examination of school children. The health interests of the insured portion of the community were placed more definitely in the hands of the general body of the medical profession, and the child was submitted at an important stage of his development to the trained medical eye of the school officer. With this should be linked the more recent direction of attention to problems of maternity and child welfare. By these several avenues it has been possible to approach and anticipate the beginnings of disease in a way previously impossible.

Those influences—and the brief catalogue might be extended—have tended to increase communal vitality and to limit the tendency to, and the ravages of, disease. They have been the cause of the gratifying drop in the general death rate of the country, urban and rural, and in the mortality rate registrable in special groups and areas. It is impossible to emphasize overmuch the sanitary advantages which have accrued from the establishment throughout the country of a uniform co-ordinated health service composed of highly trained graduates in medicine, under the inspiration of, and responsible to, a

department of the State, which in turn functions and directs in obedience to the demand of enlightened public opinion.

Those wide influences, which have been reflected in the reduction of the general mortality bill of the country, have no less certainly played their part in the decline of tuberculosis mortality. The more the natural history of tuberculosis is comprehended, the more freely will their value be admitted. No serious worker in tuberculosis will fail to give them their proper place.

Specialized Direction of Effort.

None the less, the student of tuberculosis cannot but believe that those general influences would not have brought us to the fortunate position in which we stand to-day, apart from the more definite direction and concentration of effort towards the special problem of tuberculosis. Indeed, this concentration of study with regard to an infection whose blighting properties may be traced

from the cradle to old age has actually impelled many of the advances in hygiene which our generation has witnessed. The tracing of tuberculous infection to the home, and the determination of its early manifestations in the child and of its presence in other contacts, the recognition of prejudicial influences in certain occupations, the revelation by the sanatorium of the marvellous influence of open air and sunlight, have widened the horizon of preventive medicine. The recognition and application of those principles has led to progress in other fields beyond tuberculosis.

In an address urging the establishment

of sanatoriums at the first British Congress of Tuberculosis in 1901 I ventured to say:

"It seems to me that we are on the threshold of a still wider development in the application of the open-air principle. In our treatment of disease we want to realize more fully that the action of pure fresh air is directly curative. In the adaptation of the system to other medical conditions there seems to exist the potential of successes comparable to, if not so striking in character as, those obtained in surgery through the adoption of aseptic measures."

Only the other day Professor G. M. Robertson of the Royal Edinburgh Hospital for Mental and Nervous Diseases, in pleading in his annual report for a larger outlook on mental disease, says:

"How comparable is this new psychiatric crusade to the successful campaign against tuberculosis. . . . Forty years ago patients were sent to hospitals with cavities in their lungs and in the last stages of the disease. Arrangements were therefore made to discover the disease at an earlier and more hopeful stage; out-patient clinics and dispensaries were instituted; finally, the family and the home came under review for early and preventive treatment. Let psychiatrists go and do likewise, and may they be as successful."

The forward march of preventive medicine during the past fifty years, in which members of this society have had an honourable place, has led to numerous triumphs. These have been achieved by many means—sometimes by the application of general physiological principles which, in proportion to success in application, negative disease,

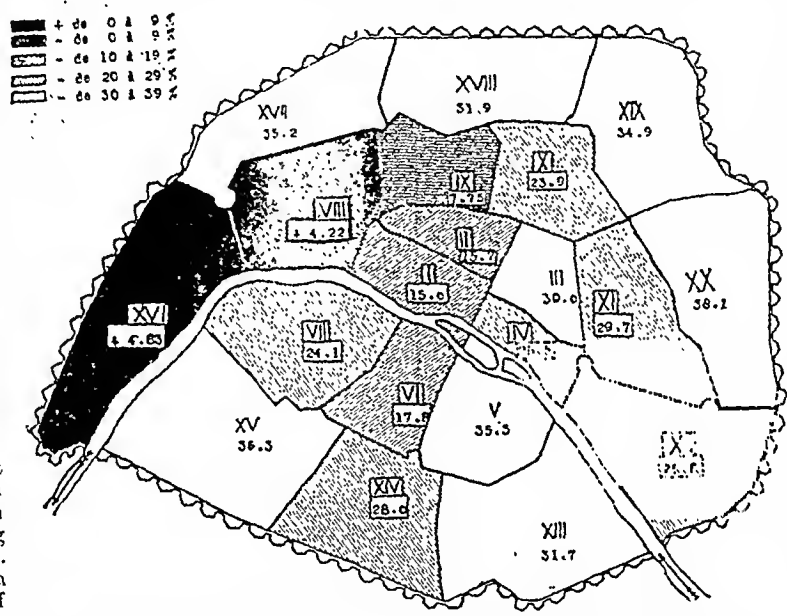

FIG. 3.—Decline of annual mean death rate from pulmonary tuberculosis in the various districts of Paris between the periods 1909-13 and 1919-23.

sometimes by specialized determination of effort towards particular issues. In relation to tuberculosis both lines of approach have tended towards the decline of mortality.

#### *A Tubercle-free Herd.*

My view regarding the control of tuberculosis in the human species is in keeping with the lines on which the farmer can establish and maintain a tubercle-free herd. When the Tuberculosis Trust of Scotland resolved to form such a herd procedure took two directions: (1) towards the elimination of infection within and the exclusion of risk of fresh infection from without; (2) towards the maintenance of the herd under completely physiological conditions of environment. The first requirement was met by the institution of careful antituberculosis measures and application of tuberculin tests, and the second by scrupulous regard to air, sunlight, space, nutrition, cleanliness, and the education of farm and dairy hands. Incidentally, it may interest members of the society to know that the young immature stock (prior to milking age) passed the whole of last summer—wet though it was—and the whole of this winter—cold and stormy as it has been—on a hill pasture at an elevation of 800 to 1,000 feet, in the open air, day and night, without one case of sickness. We began operations five years ago, and for the last three years the entire stock, numbering 109, has stood the rigid tests imposed by the chief veterinary inspector of the city.

In handling the more complex problem of tuberculosis in man, medicine has in view both sides of the shield: first, the limitation (exclusion?) of infection; second, increase of resistance. The tuberculosis scheme, as built up in this country, rests largely on these foundations. On the one hand, every fact in the natural history of the infection comes to have value, along with facts from comparative study of other endemic and epidemic diseases. On the other hand, the great physiological principles which preventive medicine has known how to harness and hitch to her wagon on other roads have been adapted to the problem of tuberculosis, and have been expanded by the convincing lesson of the sanatorium and open-air school.

#### *Scientific Patience.*

For the appraisalment of results patience is necessary—scientific patience. It is essential to remember that tuberculosis differs from other infective diseases in respect of duration and of clinical expression. It is a disease of a lifetime—it may be from infancy to old age—and its protean manifestations change with the seven ages of man. Assuming that our antituberculosis measures are sound, we cannot expect the entire effects to be registered quickly. The gains can be gradual only, with acceleration of the pace as time goes on. More marked reduction is likely to be evident at certain ages in relation to certain aspects of intensive activity. That is pretty much what we are finding—a postponement of death, a saving of life in childhood and in early adult life.

The Registrar-General for Scotland, Dr. J. C. Dunlop, to whom I am indebted for invaluable co-operation on the statistical side, has drawn my attention to the remarkable fact (Table V) that, out of a total saving of life in Scotland between the ages of 15 and 35 during the year 1921, as compared with 1891 (three-year mean), more than half was due to reduction in mortality from pulmonary tuberculosis.

To me, as a fairly seasoned hand, the outcome appears satisfactory. In so complex a situation it is hazardous to attach rigidly cause to effect. Rather than try to credit the result to this or that particular factor it is, in my opinion, more just and sound to admit that there have been numerous contributory factors. The continuous decline in mortality, the recent acceleration of that rate of decline, and the displacement of tuberculosis from chief place in the list of killing diseases, have been due to a combination of influences and activities which have found practical expression in the tuberculosis schemes of the country. To this it should be added that, when all is said and done from the side of medicine, another factor of governing importance must not be lost sight of—namely, the determination of the nation to face the issue, cost what it may.

## THE TREATMENT OF ACUTE APPENDICITIS.\*

BY

H. H. RAYNER, M.B., F.R.C.S.,

CONSULTING SURGEON, MANCHESTER CHILDREN'S HOSPITAL; SENIOR ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY.

In a consideration of the treatment of acute appendicitis it is relevant to point out that the number of deaths from this disease in England and Wales has not diminished during the past fifteen years, yet it is certain that the proportion of favourable cases—that is, the early cases—that are submitted to operation is much higher now than it was fifteen years ago, and also it is fair to assume that the improvement in operative technique during the same period must have helped to reduce the case mortality.

It may be suggested, therefore, that the maintained national mortality rate is due to an increase in the number of cases—an actual increase or an increased recognition of the disease. An examination of the annual statistical reports of the Manchester Royal Infirmary shows a steady and substantial increase in the number of these cases during the last fifteen years, but during the same period at this hospital the case mortality of the disease has fallen to such an extent that the gross number of deaths per annum at the end of the period is much less than it was at the beginning. Thus in the practice of one of the largest general hospitals in the country a steady increase in the number of cases during the past fifteen years synchronizes with a substantial fall in the actual number of deaths from this disease, and, that being the case, the maintained national mortality rate of acute appendicitis ought to be a matter of concern to the surgeon, particularly if he is also a teacher of surgery.

The foregoing remarks are based on the following statistics.

#### *Acute Appendicitis and Perityphilitis in England and Wales.* (From the Registrar-General's Returns.)

Average annual number of deaths per million persons during the four years ending 1914=70.

Average annual number of deaths per million persons during the four years ending 1926=72.

#### *Manchester Royal Infirmary.*

(a) In the three years ending 1915 the average annual number of admissions of acute appendicitis = 550, or 5.4 per cent. of the total admissions to hospital.

Average annual number of deaths from acute appendicitis in same years=69.

(b) In the three years ending 1926 the average annual number of admissions of acute appendicitis=830, or 7.6 per cent. of the total admissions to hospital.

Average annual number of deaths from acute appendicitis in same years=48.

#### POLICY OF IMMEDIATE OPERATION.

An account of the treatment of acute appendicitis cannot ignore the divergence of opinion among surgeons on the policy of immediate operation in all cases irrespective of the duration and pathological development of the disease. Surgeons in this and in all other countries in which appendicitis is prevalent agree in advocating removal of the appendix in all cases in which the disease is still limited to the appendix, before perforation or before the onset of a local or spreading peritonitis, and no one with any experience of abdominal surgery, I think, would venture to criticize this policy. It may be asserted with confidence that there is no more beneficent operation in surgery than the removal of a gangrenous or tightly distended appendix whilst this is still intact. So, too, at the other end of the scale, when a case is seen for the first time late in the course of the disease, and on the one hand there is clearly an abscess, or on the other hand the disease is manifestly subsiding without suppuration, no one would dispute the propriety of operation for evacuation of the abscess in the one or of a policy of masterly inactivity in the other. But it is in between these two stages that the surgeon first encounters the great majority of his cases; in this large group peritoneal infection has taken place which may be localized or diffuse, and even if

\* A paper read before the Manchester Surgical Society on December 6th, 1927.

localized the intensity of the infection varies considerably according to the type of appendicular lesion. It is in the treatment of cases in this group that there is some difference of opinion: though it is probably correct to say that the great majority of surgeons advocate immediate operation, and that those who advise postponement of the operation are decidedly in the minority.

The advocates of postponement, amongst whom are Sherren,<sup>1</sup> McNeill Love,<sup>2</sup> and some of the surgeons of St. Thomas's Hospital, advise that in those cases of acute appendicitis which come under the notice of the surgeon only after perforation and the onset of peritonitis, local or spreading, no operation should be performed until the patient's response to careful non-operative treatment in hospital or nursing home has been observed; that approximately in two out of three such cases the disease either will subside entirely or will terminate in a well-localized abscess which may be safely and simply evacuated after the acute phase has passed; and that those cases in which, after a period of one to three days, the disease appears to be extending, the operation can be carried out without more risk to life than obtains when the operation is carried out at once. In all those cases in which the disease subsides without operation, appendicectomy is carried out as soon as it appears wise to do so. In support of this policy of delay is urged: (1) that the mortality rate in this large group as a whole is reduced; (2) that the incidence of post-operative complications is substantially reduced; (3) that the period of illness and disability is shorter and less trying to the patient.

My own opinion in this matter is largely influenced by the experience of a recent series of 245 consecutive cases of acute appendicitis, all of which have been under my care and have been closely observed by me. No cases which were manifestly settling down at the time I first saw them have been included in this series. In 52 of these the operation was postponed, and it should be said that in selecting these at the time of the first examination I chose them from the large group of local peritonitis cases, and in no case was operation deferred for spreading or diffuse peritonitis. All of them were treated in hospital or nursing home. The results in these 52 can be grouped in three classes:

A.—Twenty-eight settled down completely within one to two weeks. All but 3 had appendicectomy performed a few weeks after settling down. There were no deaths and no complications. There is no doubt in my mind that many of these cases scored heavily by this policy.

B.—Twelve cases terminated in the formation of a local abscess which required operation for drainage; in 8 of them it was impossible to remove the appendix, but of these all save one submitted to appendicectomy a few weeks later. There were no deaths and no serious complications in this group, though the healing of the drainage track occupied four to six weeks in three of them.

C.—Twelve cases required operation during the acute stage after periods of delay varying from one to four days. There were 3 deaths; of these, 2 were due to intestinal obstruction, which in one case was present at the time of operation and was the reason for the operation, and in the other it developed three weeks after the operation when the patient was ready for discharge from hospital; one death was ascribed to acute toxæmia a few hours after operation; in this case the operation was not performed by me, but as I advised delay in this case, and two days later advised operation, it is right to include it. Of the 9 cases that recovered the appendix was removed in 8. In one of them the condition of the patient unquestionably became much worse during the period of delay, owing to toxæmia from a progressive abscess and to associated ileus. He was only retrieved by operation for evacuation of the abscess and mobilization of the terminal ileum, followed by assiduous after-treatment.

In 193 cases (approximately four-fifths of the whole series) the operation was performed without delay after the first examination irrespective of the duration or stage of the disease. These may be grouped into the following types.

#### GROUP A.—Appendix not Perforated (65 Cases).

Many of these cases were instances of gangrenous appendicitis, and several yielded a history that covered more than two days—the conventional duration of the pre-perforative stage.

There was one death from pulmonary embolism eleven days after operation, in a stout woman of alcoholic habits.

Complications.—One patient developed panophthalmitis twenty-eight days after operation; two weeks after operation, when apparently well, he was allowed to get up; the temperature rose the same night and assumed a septicaemic type for the next four weeks. The eye was eventually removed. In the notes on the operation made by me the same day it is stated that the appendix, a high retrocolic one, was entirely gangrenous, and

during extraction some leakage of its contents was unavoidable; the wound suppurated a little. There was one case of minor pulmonary embolism. In 6 cases there was a mild degree of wound suppuration. There were no cases of post-operative pneumonia.

#### GROUP B.—Local Peritonitis (84 Cases).

The cases in this group had pus in the peritoneal cavity around the appendix, usually associated with perforation of the appendix, but in several there was no visible perforation.

There were two deaths, one from intestinal obstruction that began six days after operation for pelvic peritonitis—a case with a history of only twenty-six hours' illness before operation. The other death was from septicaemia (? portal pyaemia) eight weeks after operation and two weeks after discharge from hospital. This man was in good condition when discharged home, but there was a clean sinus in the wound; his home surroundings were very bad, and the dressing was done by his aged wife.

Complications.—There were 7 cases of post-operative pneumonia (4 of these were in children under 12 and all except one were on the right side). One patient had intestinal obstruction, subacute, and recovered without operation. There was one case of pelvic abscess requiring drainage by the rectum fourteen days after operation, and there was one case of subphrenic abscess.

#### GROUP C.—Spreading or Diffuse Peritonitis (31 Cases).

The condition was always associated with a visible perforation in the appendix or with a leaking appendicular abscess. In the former type the history in 17 cases did not exceed forty-eight hours; in the latter type the history clearly fell into two phases—the first phase of moderate pain and vomiting, often not causing total incapacity, and the second phase, beginning two to four days later, marked by sudden onset of very severe pain and more or less collapse. Only 2 cases could be classed as having general peritonitis, and these account for 2 of the deaths.

There were 4 deaths in this group, as follows: One case of ileus and secondary haemorrhage of undetermined origin despite post-mortem examination—case of general peritonitis. One case of general peritonitis four days after operation—case of general peritonitis at operation; post-mortem examination. One patient died under the anaesthetic—ethor convulsions. The fourth death was that of a patient with ileus plus pulmonary oedema superimposed on chronic bronchitis and emphysema. After admission of this patient to the home the operation was delayed for twelve hours because of his bad general condition; in addition to chronic bronchitis he was very fat and heavily addicted to alcohol. His condition appeared to be worse, locally and generally, after twelve hours, and I regarded his chance of recovery as very small with or without operation, but as slightly higher with operation.

Complications.—One case of acute intestinal obstruction seven days after operation; the patient recovered after enterostomy. One case of pelvic abscess requiring drainage by the rectum. One case of subphrenic abscess drained two and a half months after operation. Four cases of pneumonia of the lower lung—on the right side in three and bilateral in one. Two cases of breakdown of wound with extrusion of bowel on to the abdominal wall on the seventh and eleventh days respectively. Both were associated with severe wound infection and persistent cough. Both recovered after re-suture and support of the abdominal wall by adhesive strapping.

#### GROUP D.—Abscess (13 Cases).

This group consisted of patients with a history of seven to fourteen days' illness. There were no deaths. The appendix was removed in 4 cases only. The one complication was in a patient with a minor type of pulmonary embolism.

The summarized results in the whole series is as follows:

245 consecutive cases with 10 deaths, or mortality rate of 4 per cent.

193 cases were operated upon at once with 7 deaths, or mortality rate of 3.6 per cent. All these, except those admitted in the terminal abscess stage, had the appendix removed.

52 cases had their operation postponed with 3 deaths, or mortality rate of 5.7 per cent.

In 27 of these operation had to be performed during the acute stage or because of abscess, and in 9 the appendix was not removed.

It may be that it is misleading to compare these two mortality rates, for the cases operated upon at once include 62 in which the appendix had not perforated and in which there was no marked degree of local peritonitis, whilst all the deferred ones presented clinical evidence of local peritonitis; on the other hand, the deferred cases do not include the more severe types, for in no case was the operation postponed in diffuse or widespread peritonitis. Remove the non-perforated cases altogether and the mortality rates are 4.6 and 5.7 per cent. for immediate and deferred cases respectively.

In attempting to measure the value of the policy of delay I attach more importance to consideration of the features of the more severe cases in each group. Of the 7 patients who died in the immediate class, in 3 the duration of the illness before operation did not exceed thirty hours; 2 of these had perforated and had pelvic peritonitis, and I think it very doubtful if the advocates of delay after perforation would have elected to practise the method in

such early and severe cases; one (death from pulmonary embolism) had not perforated, and is therefore irrelevant in this argument. Of the 4 remaining deaths, one, a youth in relatively good condition, died of ether convulsions during the operation, and the 3 others presented at the operation such widespread peritonitis, coupled in 2 with a very unfavourable general condition, that there is not the slightest ground for thinking that delay would have altered the issue in any ease. As already stated, in one of them a delay of twelve hours was made on account of the patient's unsuitability for anything but imperative surgery. Now of the 3 deaths in the unsuccessfully delayed cases, one died of acute intestinal obstruction during convalescence, and his death cannot, in my opinion, be attributed to the delay in operating; but in the matter of the 2 other deaths I felt at the time that their prospects of recovery had been reduced by waiting. Then of the 9 who recovered after a delayed operation done in the acute stage, one at least ran a much greater risk than he would have done if he had been operated upon when first seen. Deterioration of the patient undergoing non-operative treatment for appendicular peritonitis is not merely due to extension of the peritonitis or an increase in size of the abscess, but often is the outcome of ileus caused by implication of the lower ileum in the walls of the abscess cavity, and to the resulting inflammatory infiltration of the bowel wall.

Of the 115 cases with local or diffuse peritonitis which were operated upon at once the majority of these made rapid recoveries (70 of them were soundly healed within two and three weeks), and all without exception had the appendix removed. It seems highly improbable that the delayed method would, if it had been employed in all of these, have given results nearly so good. I am therefore opposed to the policy of delaying operation in all those cases of acute appendicitis in which perforation and peritonitis, local or diffused, has occurred. I think any policy based on a sharp distinction between the periods before and after perforation is unsound. Some of the worst cases in which operation is urgently required are those that begin with perforation; I have operated upon several such cases within four to six hours of the first symptom and found a large perforation, whilst in the less acute types it is frequently not possible to determine with precision whether perforation has or has not occurred—particularly so in pelvic cases. So, too, any policy based on the duration of the disease—that is, a policy which lays down that cases seen within the first forty-eight hours should be operated upon at once, but that in those seen after the second day and up to the fifth or sixth day the operation should be delayed—is ill founded; observations on operations, if correlated with the history of the case, will show that time and pathological progress do not keep pace. In my belief some of the third-day cases are those in which the immediate operation is most essential, in view of the pathological conditions revealed at operation, and, in the hands of an experienced operator, the great majority of such cases do very well. To hold these opinions is not to believe that every case of acute appendicitis should be operated upon at once simply because the disease is regarded as active. It is certain that a considerable proportion of cases, even after the occurrence of peritoneal infection, will subside under proper treatment without operation, and that if we were able to pick out these cases we might in many of them defer the operation, with great advantage to the patient, to a quiescent period. But to make this distinction in all it is necessary to keep the patient under observation for one to three days, and most surgeons feel that the advantages to the patient who does settle after this period are outweighed by the increased risk to the patient who does not. However, I believe it is possible to exercise discrimination in some without adding to the risk of the others.

After all, the tendency in the past twenty years has been to put the operation for acute appendicitis almost on the same footing in the matter of urgency as the operations for acute intestinal obstruction and perforated gastric ulcer, and in 10 per cent., or possibly 20 per cent., of the appendicitis cases this is correct. But is it right on that account to abandon all effort at discrimination in regard to the 80 per cent., especially in view of the commonness

of the disease and the consequence that the operative work must therefore at times be performed by those whose training and experience do not fit them to undertake such an important and serious operation? In seeking a basis for this discrimination, though I have argued that it is unwise to attempt a hard-and-fast division into classes according to lapse of time or occurrence of perforation I think we may from our clinical experience and observations at operations recognize certain types in which it is safer, and in other ways better for the patient, that immediate operation should not be undertaken. Such for example, as the following.

1. The patient who presents a firm hard mass in the right iliac fossa, in the right loin, or over the fore part of the iliac crest; the mass is ill defined at its edges, is often extensive, and is free from marked tenderness. The history shows a duration of four to eight days, and during much of this time the patient has had insufficient or no treatment; he has been out of bed and possibly at work. Such a case will commonly subside entirely under proper treatment; much less frequently the mass will slowly resolve itself into a well shut off abscess, which can be easily and safely opened. An immediate operation in such a case is likely to prove difficult and unsatisfactory to the surgeon, and the convalescence following it will be protracted and troublesome. Furthermore, an operation performed as an emergency in this type of case will now and again disclose a mistake in the diagnosis—a mistake which may involve the surgeon in an operation for which neither he nor the patient is suitably prepared.

2. The patient in an earlier stage of the disease, with a history of two to four days' illness not marked by a severe onset, who presents an area of well-localized muscular rigidity, without extreme tenderness, over the appendicular site. His temperature is raised, his pulse moderately accelerated; the increase of both is often accentuated when first seen by recent transit to hospital or home. Such a patient is by no means always best dealt with by immediate operation, and the following circumstances should be regarded as indicating a temporizing policy in this type:

- (a) Retrocolic position of appendix as shown by position of rigid area and of maximum tenderness.
- (b) Condition of patient unfavourable for an abdominal operation without a period of observation and preparation by reason of stoutness, chronic bronchitis, especially if there is much emphysema, alcoholic habits, and senility.
- (c) History of many attacks of approximately equal severity in the few years preceding this attack.
- (d) An environment unfavourable for a serious abdominal operation and for the necessary after-care of the patient.

On the other hand, a patient of healthy type who presents localized but well-marked rigidity accompanied by extreme tenderness, and whose history indicates a severe onset or a severe exacerbation since onset, should generally be operated upon without delay. So, too, evidence of a pelvic position of the appendix or of spreading peritonitis is strong ground for the performance of an immediate operation.

Finally, I would suggest that in those cases in which the disease is allowed to subside without operation it is wise to allow an interval of three to eight weeks before undertaking appendicectomy; a long duration of the process of settling down demands a long interval before appendicectomy.

#### TECHNIQUE OF THE OPERATION.

**Incision.**—There is no incision that can be called the best of the three—the gridiron (McBurney's), the Battle, and the paramedian—which are in common use. I prefer the paramedian in most cases. I particularly employ it in cases of diffuse peritonitis and of pelvic peritonitis, and if in such cases drainage of the peritoneal cavity is required it can be satisfactorily employed through this incision without making an additional stab wound. The tube should be made to pass through a slit in the rectus muscle so as to allow this structure to fall back into its natural position. In the case of suppurative peritonitis localized in the right iliac fossa this incision may be objected to on the ground that the operation crosses the

# SOME NOTES ON DIAGNOSIS.

APRIL 28, 1928]

peritoneum to reach the infected field: as a matter of fact, an approach to an infected area which at the outset allows the boundaries of this area to be determined and maintained by suitable packing is often better than an approach which conducts at once to the centre of the affected area. The McBurney incision is well established and its advantages well realized. In easy cases it is admirable, but the clean removal of a pelvic or a high retrocolic appendix may present considerable difficulty through this incision; so, too, the exposure of the pelvis in cases of pelvic peritonitis is inferior to that obtained either by the pararectus or Battle's incision. Incision for drainage of an abscess should be made as small as is compatible with good access, and in such a position as to afford the most direct route to the abscess cavity. Pelvic abscesses which are pressing down on to the anterior wall of the rectum should be opened through the rectum in either sex.

In the performance of the operation, after the protection of uninfected areas of the peritoneum and as far as possible of the edges of the wound, and the gentle wiping away of any pus that may be present, the location of the appendix is determined. The extraction of an unperforated but friable or even gangrenous appendix without rupturing it or allowing the slightest leakage of its contents is by far the most important step in the operation for acute appendicitis in its preperforative stage; if the appendix is firmly embedded in a retrocolic or pelvic position it is generally better to remove it by first dividing its base, invaginating the caecal stump, and then dividing the appendicular attachments from base to tip. For this procedure a free exposure is required. The intact removal of a gangrenous but unperforated appendix is followed by a recovery indistinguishable from that following a quiet appendicectomy, but rupture of such an appendix during removal is likely to have a serious sequel during the period of recovery, though the association is easily overlooked. In cases of pelvic peritonitis, particularly the type in which the pus is confined to the right posterior quarter of the pelvis by the terminal ileum and its mesentery, which together overlie the appendix and surrounding pus like a hood, it is important after removal of the pus and appendix to set the ileum free from the fibrinous adhesions that bind it to the post-pelvic wall. The condition of the ileum must also be carefully inspected; in the presence of a foul-smelling abscess around a gangrenous appendix the ileum may be intensely hyperaemic and its walls swollen and rigid and here and there covered by plates of necrotic lymph; bowel so affected is often contracted and flattened. Such a state apparently indicates an absolute incapacity of the bowel to transmit its contents, but rarely is it necessary to do more than insist on a rational plan of after-treatment. There is no need to short-circuit the bowel or to perform enterostomy, but for the next forty-eight hours or more the patient should receive practically the whole of his fluid requirements by means of the subcutaneous injection of saline solution—by mouth only a minimum quantity of water to allay thirst should be allowed. After forty-eight hours gradually increasing quantities of water may be allowed as the subcutaneous supply is withdrawn. In widespread peritonitis this plan of after-treatment is also of the greatest value.

In regard to drainage of the peritoneum, the tendency of the majority of surgeons to employ drainage less and less has been a feature of the surgery of acute appendicitis during the post-war period; and it would seem that the results on the whole amply justify this tendency. Space forbids me to say more than that dispensation with drainage should depend, not on boldness of spirit, but on good technique in the performance of the operation. This subject has been ably dealt with by St. Leger Brockman<sup>2</sup> in a recent Hunterian Lecture.

## After-Treatment in Cases of Pelvic and Diffuse Peritonitis.

(a) The amount of water allowed by mouth should be severely restricted during the first forty-eight hours because of the functional impairment of the lower small intestine; fluid must be given freely, but by rectal or subcutaneous routes—by the latter more particularly when the ileum is known to be badly damaged.

(b) Purgatives should not be given; a simple enema every day or on alternate days will suffice to empty the colon of its contents.

(c) Abdominal distension, griping pains, and vomiting of intestinal contents on the third to fifth days are often due to failure to realize the importance of measures (a) and (b). In the presence of these symptoms stomach lavage should always be tried before contemplating operation. If operation proves to be necessary, then enterostomy, by a self-closing method above the highest inflamed loop of small intestine, is probably the best measure.

(d) Lastly, beware of the patient who has a persistent cough and a badly infected wound—as sometimes follows operation for a virulent and widespread peritonitis; if the sutures are seen to be cutting deep slits in the skin, then the wound edges should be firmly approximated by adhesive strapping (this is laced across the wound so that the plaster is not removed for dressings). Timely resort to this device will prevent a catastrophe.

# SOME NOTES ON DIAGNOSIS.\*

BY

CLAUDE WILSON, M.D., M.R.C.P.,

CHAIRMAN OF THE TUNBRIDGE WELLS DIVISION: LATE PRESIDENT OF THE KENT BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

WHEN invited to read a paper at this meeting I recognized an opportunity for discussing some rather unconventional views on diagnosis—views which in one form and another I have held since my student days, and which have by no means been dispelled by the great additions made to medical knowledge during the intervening years.

Diagnosis is our first object when seeing a fresh case. Our patients demand a diagnosis, and our teachers have ever impressed on us the prime importance of making one, while from time to time an eminent authority deplores the lack of diagnostic accuracy in some widely read journal in a way which would seem to imply that an accurate diagnosis is possible in every case. In hospital diagnosis is at its easiest. The cases are mostly advanced examples of well-marked disease, and the means and methods of exhaustive investigation are at hand. Yet difficult cases are seen; and, in my younger days, a fairly regular attendance in the *post-mortem* room revealed much that had not been anticipated—just as it so often does on the operating table—and I early learned that the most confident diagnostician is seldom the most reliable.

It is well to recognize our limitations as well as our advances. Unless a case is trivial or transient or obvious, we are at once in difficulties. The clinical pathologist, the radiographer, and the expert specialist often help us to a conclusion, but we are perhaps as often left in doubt. The same may be said of the general consultant, whose knowledge, experience, and authority, though of signal value in confirming an opinion already reached, or in bolstering up our ignorance, too often fail to carry us much further. Still, we may generally trust the man who is not afraid to say he does not know; when he thinks he does know he is generally right. But the pronouncements of the pundit who courts the reputation of being able to diagnose every case are necessarily unreliable; the fact being that, up to the present time, a diagnosis that is more than a guess is, at the stage of the disease when it would be most helpful, often quite impossible.

## The Relative Value of Clinical Methods.

The aspect and demeanour of the patient are sometimes so characteristic that a diagnosis can be made at a glance. No one can mistake the tabetic, the Parkinsonian, or the fully developed case of Graves's disease. The history of the patient's complaints and sensations can hardly be too carefully elicited, for the key to the trouble

\* An abridged version of a paper delivered before the Tunbridge Wells Division of the British Medical Association.

is often found here, while the family history and collateral evidence may be of equal value. Still, it is upon evidence obtained through the trained senses that one must depend in all but obvious cases. I propose to offer a few words on the kind of help which each of the senses provides, and in so doing it will serve my purpose best to begin with those which help us least and keep the most important to the end.

Taste hardly counts, though it is historically associated with the diagnosis of diabetes; and, while the olfactory senso may be conclusive, as in alcoholism, ozæna, acetonaemia, and *B. coli* abscess, its scope is strictly limited. Touch and hearing run a close race, though hearing wins easily if we include what is learned from the preliminary inquiry, and from the character of the patient's voice and utterance. In physical examination these two often help each other out, as in the tuning of a thrill and a murmur, and in the feeling of resistance which accompanies the percussion note of apical consolidation and pleural effusion. But percussion generally depends on the sense of hearing alone, and the ability to detect slight differences of sound varies very much in different individuals. I never believed that it was possible to map out the stomach by percussion, and the advent of the x-ray meal has put it largely out of court. Most misleading is the percussion of adjacent gas-filled viscera. A few weeks ago I tapped with two coins over the epigastric and adjacent areas, while a colleague moved his stethoscope about, and pronounced the stomach to be greatly dilated. But a stomach tube failed to bring off any gas, and an hour or two later the coils of an enormously distended small intestine were found to fill this area, indeed the whole of the anterior segment of the abdomen. The only thing certain about percussion of adjacent hollow viscera is that the results are uncertain. To a lesser extent, for the possibilities are less egregious, I have always held as suspect the percussion line of the left border of the heart. Very different outlines are made by equally capable observers of the same case, and I have frequently found that the radiogram is smaller than the area mapped out by percussion.

Auscultation, of course, yields invaluable information as to both lungs and heart, but it is well to bear in mind what erroneous doctrines have been taught through many decades, not because the auscultation was at fault, but because the deductions were founded on theories which have proved to be erroneous. It need not have taken about a hundred years to find out that a systolic mitral murmur was often quite harmless. Possibly the most unequivocally useful information rendered by the stethoscope is connected with the recognition of the foetal heart beat.

Coming to the tactile sense alone, and using the term in its widest significance, so as to include recognition of tenderness, heat, cold, resistance, and fluctuation, we find an immense amount of information available. Texture, irregularity of surface, foreign bodies, crepitus; the examination of the pulse and the heart; aneurysm; fremitus and friction; and the exploration of the throat and pelvic organs, carry us far. And the reflexes are probably destined to carry us much further than is as yet generally recognized.

If I have run rapidly through some points connected with the diagnostic value of what we may almost call the minor senses, it has been mainly for the purpose of bringing into contrast the overwhelming importance of the sense of sight. It has been very largely in proportion to the degree in which different divisions of clinical knowledge have been brought within the range of vision that our powers of diagnosis have increased, and, fortunately, the range is being continually extended. The general glance, which, as already mentioned, may be diagnostic, is much more often suggestive. Pallor and cyanosis, obesity and cachexia, facial expression, lameness, and similar features, give us leads which are generally true. The distortions of surface produced by fractures, dislocations, tumours, and hernia are, of course, obvious. Beyond this the skin and the tongue and the throat can be seen unaided; sputa and excreta can be inspected, and urine tested. For the rest we must rely upon instruments, and while the use of almost

all instruments requires practice, the interpretation of the results requires more, and invariably lags behind. Probably in all cases interpretation will ever be liable to revision and extension. What should we know of pyrexia without the clinical thermometer? Yet while a glance at a temperature chart, along with its record of pulse and respiration, may be in itself diagnostic, who will say that we are at the end of the knowledge which this simple, little instrument may bring? It is only quite recently that the characteristic charts of lymphadenoma and rat-bite fever have been recognized.

What would be our knowledge of the diseases of the eye and of the nervous system without the ophthalmoscope? And what should we know of the larynx if it could not be seen? What would our general knowledge of disease be without the revelations of the microscope, with its histological pathology, its blood counts, and the intricacies of bacteriology? Without transillumination a filled antrum is a sealed book, and the new knowledge of heart disease depends essentially on visible tracings.

The cavities of the body in the immediate vicinity of the orifices have for long been explored by means of specula, but the ingenious applications of electric light which provide us with cystoscopes and sigmoidoscopes, and with appliances by means of which the mucosa of the stomach and other remote internal surfaces are being brought into view, are matters of yesterday. The advent of x rays soon brought the accurate diagnosis of fractures and dislocations, and the localization of foreign bodies; the sockets of the teeth, the pituitary fossa, and the contents of the thorax were brought into the available field later; and while the exploration of the gastro-intestinal tract by means of barium meal and enema seem to have been long enough with us, the discovery of lipiodol and similar substances has recently added the bronchi, pulmonary cavities, the gall-bladder, the pelvis of the kidney, and the ramifications of sinus and fistula to the internal regions explorable by sight. The objection is sometimes raised that skiagrams may give misleading information. But this applies to all diagnostic methods, and skiagrams, like electro-cardiograms, may need expert elucidation. In obscure cases the experts themselves may be puzzled. None of the new methods has reached its zenith, and interpretation, as already stated, necessarily lags behind observation.

It is not without purpose that I have emphasized the paramount value of vision in diagnosis; it is not without purpose that I pass on to a few observations about the skin.

#### *Disease Manifestations in the Skin.*

Those parts of the body which are most open to easy and complete examination by sight and by touch ought to be those about which we know most, and in which changes due to treatment, general and local, should be most obvious. If such an area is also that most accessible to microscopic investigation, general and bacteriological, surely every facility exists for obtaining full knowledge of its physiology, its pathology, the diagnosis of its diseases, and their successful treatment. Yet if there is one part of the body which seems more puzzling than the rest, both as to diagnosis and as to treatment, I feel sure that a good many of us would think of the skin.

The experts who gather at the meetings of the dermatological societies often exhibit rarities and curiosities, and one may often notice the words "Case for diagnosis" on the agenda. Truly the skin is a humiliating structure. The limitations of our knowledge as to the essential nature of a lesion, and of its etiology, progress, and treatment, are here so obvious that it is not easy to deceive either ourselves or our patients; and many have said or thought that we know less about the skin than about almost any other system. Yet it may well be that, as should surely be the case, we do know more about the skin than about any other part; and that our ignorance of the invisible organs and systems may still be as profound as was our ignorance of the diseases of the fundus oculi before the days of the ophthalmoscope. There are but few skin diseases concerning which our knowledge may be said to be complete. One such is scabies; the cause is clear, the lesions are characteristic, and the treatment is known and is curative.

With the syphilides the case is different; the ultimate cause is known, but why should the lesions be so strangely varied? Why, again, should the ubiquitous staphylococcus have so pronounced an attraction for the skin of the adolescent? And if endocrine instability is evoked, why should it select its unfortunate victims so capriciously? Of many well-known skin diseases we really know nothing as to the essential nature or cause. Of individual lesions we know that vesicles and pustules arise from very different causes—local irritation and infection, certain drugs, small-pox, and so on; but, except in the case of burns, trauma, and local infection, we know nothing of the reason.

Transient anomalies seem, if possible, to be even more bewildering. How strange are the characteristic rashes of the exanthemata, each with its distribution and its period of incidence and decline; and perhaps still more curious are the pallors, flushings, and sweatings from emotional causes, each being part of an immediate response to purely psychic influences involving widespread nervous endocrine and circulatory adaptations in many parts of the body, but of which the skin reactions are alone in evidence. What effect does emotion have over other secretions? We know something of occasional renal response, and a good deal about tears. Emotion may cause profuse weeping or may dry up tears. What effect may it have on the gastric and biliary secretions? Doubtless profound effects, of which emotional vomiting, appetite juice, and the suggestive comments accompanying a carminative prescription are mere hints. What is the meaning of the muddy pallor with brownish wandering patches seen on the face in seasickness and in other conditions in which bile regurgitates? We see these things on the skin, but what is the liver—that immense organ which works in silence and in darkness—doing? All we can say is that we don't know. At a recent operation in which the liver was exposed I noticed little blisters which came and went and wandered, raising the capsule as they moved. What was going on within the recesses of the organ? We talk glibly about the liver being "out of order," but we do not know what is happening, and extreme cirrhosis, which had never even been suspected, may be discovered in the *post-mortem* room. One might dilate similarly upon other organs which, like the liver, work in silence and out of sight.

It is on the skin that we do see what is actually going on, and it is here that we may best gauge the extent of our knowledge and of our ignorance; and, surely, the balance is heavily weighted on the side of ignorance. And do not the grey, brown, black, and strawberry furs, and the enrious wandering rashes of the tongue, and the little ulcers and haemorrhages on the gums and on the cornea, point in the same direction? Doubtless analogous pallors, flushings, swellings, furs, ephemeral ulcers, and desquamations occur with equal frequency in unseen areas, and accompany and perhaps account for symptoms for which we have daily to invent mythical reasons.

#### What Constitutes a Diagnosis?

In discussing any question it is well to know what we are talking about. Which of us, asked to define the word "diagnosis," could supply a definition acceptable to all? In the first volume of the *James Mackenzie Institute Reports* (1922) there is a paper on the results of a collective investigation which had "the primary object of determining in what proportion of the cases met with in general practice it is possible to arrive at a diagnosis," and the first difficulty encountered was that no satisfactory definition of the word could be found. After much debate the following was framed: "The recognition in the patient of a known disease from the symptoms which are characteristic of it." If we agree to include signs under the term symptoms, as Mackenzie always did, the definition will satisfy most of us. But the difficulty which was next experienced in separating what may be fairly called "known diseases" from among "the maze of symptoms and so-called diseases in which medicine is becoming lost" was a real one, and one which we shall all do well to bear in mind. Space forbids more than the briefest epitome of the paper. A classification wide enough to embrace all cases was evolved; the "known" (diagnosable) diseases were divided into five classes according to whether the

cause was known, surmisable, or frankly unknown, while end-results, such as the valvular lesions, and secondary diseases, such as cystitis, each received a separate compartment. Of the 784 consecutive cases investigated a "diagnosis" was made in only 28 per cent., while in 22 per cent. a partial or provisional diagnosis was allowed. But just half of the cases examined did not present the symptoms characteristic of a "known disease," and were consequently scheduled as "undiagnosable." Some of these cases were simple ephemeral complaints; some were isolated symptoms, such as unexplained headache, insomnia, tinnitus, and so on. Many were examples of groups of disjointed symptoms such as we often meet with and which bring discredit on the profession, because one doctor attaches one label and another another.

"We endeavoured," says the paper, "to divide the undiagnosable class into groups—for example, intestinal toxæmia, neurasthenia, dyspepsia, etc. It might be better not to employ such terms at all, as they are apt to give an unconscious bias in favour of one theory over another. The undiagnosable cases," it concludes, "are apt to cause despair to the general practitioner, but if they are viewed rightly they present him with an invaluable field of study which is really open to him alone."

The reason why the field is "open to the general practitioner and to him alone" is that he is the only man who has the opportunity of following up his cases from month to month and from year to year. By patient observation, record, and study Mackenzie differentiated the cardiac arrhythmias, which had at first caused him "despair," and real knowledge of heart disease dates from these researches. It was only while engaged in general practice that he was able to follow up his cases as he did. But he was alone in his feelings of despair; his contemporaries were satisfied with theories now known to be erroneous.

Turning to the mass of ailments which still are "undiagnosable," how many of us are there that recognize them as such? Are they really apt to afflict us with despair? Are we not prone to think that we hold the key to the bulk of these anomalies? Did we not, thirty years ago, ascribe countless ills to "uric acid"? Was there not a time—not long gone by—when the "up-to-date" practitioner had a vaccine for almost everything? That "blood pressure" should ever have been a popular "diagnosis" seems almost as strange as the queer idea that everything could be "Coned." These things may have had their day, but many of us become obsessed by the new or revived ideas as they come along, and perhaps it is the word "toxæmia" that is now on top of the wave. Toxæmia may be obvious, or probable, or problematical, but the relegation of its origin to the colon is often no more than a guess, even when faecal analysis seems to point that way.

The colon has had a long innings, but the early canonical axiom, "Cut it out and cast it from thee," has disappeared, while the more recent advice, based on high transpontine authority, "Grease it and leave it alone," is disregarded. Sour milk had a look in some twenty years ago, and fizzled out. Possibly *acidophilus* may share a similar fate. To "change the flora" may prove as difficult as to "disinfect." But we are on firmer ground when the escape of organisms can be proved. Rowlands<sup>1</sup> has shown that the intestinal wall of rats fed on a full vitamin B diet was more than twice as thick and firmly knit as in the case of the controls; and in the few cases where he tried the treatment he found that urine which was teeming with *B. coli* "soon became sterile when the patient was placed upon a concentrated vitamin B diet." May not the well-nourished intestinal wall also prevent the absorption of toxins?

The vitamins have removed several obscure diseases from the region of bewildered speculation into the very front rank of diagnosable diseases—that is, into the small but ever-enlarging class in which the cause is definitely known. But the work by which these results have been secured has not come from the general practitioner. In endocrine disease also the best work has come from the laboratories and the schools; and, though the practitioner has by therapeutic experiment discovered various forms of sub-thyroidism, and done hopeful work with parathyroid and perhaps with other hormones, his blunderbuss work—generally the result of commercial suggestion—has been terrible. I sometimes wonder how many blunderbuss

preparations would produce any result at all if the thyroid element was cut out.

If therapeutic experiment along toxicæmic, endocrine, and similar lines can be called "investigation," we general practitioners are doing our duty nobly. But I see little of the patient laborious research to which Mackenzie devoted his life—these two kinds of inquiry lie poles asunder. Mackenzie's standard is too high for most of us; we lack the insight, even if we possessed the energy.

Is there not, however, some midway line along which we may all hope to do a little real, and possibly useful, work? There may be many; but anyone who forms the habit of taking short notes—if only of cases which are obscure or which possess some points of special interest—finds in the course of a few years that a fund of material has accumulated some of which will certainly throw light on his subsequent reading and experience. Much useful work which, among other results, helps to elucidate diagnostic problems, depends essentially on the existence of some such store. Further, if we keep our eyes open we all occasionally come across cases—or possibly cases in series—of obvious illness which, after careful investigation, are not found to conform to any known disease or even label. Such cases ought to be recorded. The work is seldom wasted, nor is it without reward.

A curious comment on the line of thought I have been pursuing is that, while a store of notes, such as I have referred to, has served me in good stead when impelled to deal with such matters as cardiac murmurs,<sup>2</sup> or the effects of opium on Cheyne-Stokes breathing and cardiac asthma,<sup>3</sup> it has been the cases I have recorded as undiagnosable which have been noticed in quarters never anticipated, and have brought me unexpected recognition. A case of sudden death in a subject who had never shown cardiac symptoms, but which proved to have been due to the rupture of an aneurysm of the ventricle,<sup>4</sup> has, I learn, been used by certain teachers in both hemispheres as an example of this (happily) undiagnosable condition; while a series of large spleens, recorded in the early nineties, presenting anomalous symptoms and occurring in three generations,<sup>5</sup> is quoted as the initial link in the chain which led to the differentiation of acholuric jaundice,<sup>6</sup> now a "known disease" with very characteristic features. These are examples of the fact that records which seem useless or lost may prove to be what some other observer is looking for, and that crumbs scattered on the waters may return to us after many days.

## VOLVULUS OF THE SIGMOID.\*

BY

GARNETT WRIGHT, F.R.C.S.,

SENIOR HONORARY SURGEON, SALFORD ROYAL HOSPITAL.

**VOLVULUS** is a comparatively rare primary cause of intestinal obstruction in this country, though in some parts of Russia and Eastern Europe it forms approximately one-third of all the cases of intestinal obstruction, while many of the cases recorded in English literature concern Indian subjects.

Rokitansky described three forms of volvulus: (1) rotation of the bowel on its mesenteric axis; (2) rotation of the bowel on its longitudinal axis; and (3) the intertwining of two coils of intestine. By far the commonest of these, so far as the sigmoid colon is concerned, is the first, and it is to this variety that I shall confine my attention.

As far back as 1878 Leichtenstern clearly described the anatomical conditions necessary for the production of this form of volvulus. These are a long mesentery with a narrow attachment to the abdominal wall. Clearly the length of the mesentery is a developmental question, and the same is probably true of the narrowness of its attachment.

\* A paper read to the Lancashire and Cheshire Branch of the British Medical Association.

Many writers have stressed the influence of chronic constipation in producing hypertrophy and dilatation of the sigmoid and in setting up chronic inflammatory changes in the meso-sigmoid leading to contraction of this structure. These changes are especially seen near the attachment of the meso-sigmoid to the abdominal wall, and lead to narrowing in this region. It is much more probable that the constipation so frequently present is the result of the anatomical peculiarities—namely, the omega loop arrangement of the sigmoid colon, which is looked upon by some authors as a mild form of idiopathic dilatation of the colon. The changes in the meso-sigmoid consist of fibrous bands on the peritoneal surface and not of fibrous changes in the structure itself, and probably result from plastic peritonitis set up by repeated attacks of partial strangulation. We shall see later on that these attacks often occur before the final acute attack takes place.

To sum up, the anatomical factors necessary are a long meso-sigmoid with a narrow attachment to the abdominal wall. Both of these may be congenital—that is, a condition of meso-sigmoid with, in some cases, an exaggeration of the normal V-shaped attachment of the mesentery. The narrowing of the base of the mesentery may be increased by repeated attacks of partial strangulation leading to the formation of fibrous bands on the base of the meso-sigmoid.

When these factors are present an attack of volvulus may be precipitated in various ways. Undoubtedly, constipation, by loading the bowel, may so increase its weight that the loop falls into the pelvis and the root of the mesentery becomes twisted. The resulting obstruction produces a distension of the bowel and the twist becomes increased. Finally, the circulation is obstructed and still further distension follows, and the picture becomes complete. In many cases the exciting cause is a powerful aperient taken to relieve the constipation. Sometimes an acute attack is produced by violent physical exertion, the movements of the abdominal wall pressing on a loaded and enlarged sigmoid and twisting it on its mesenteric axis.

It is a significant fact that volvulus is commoner in men than women owing to the stronger abdominal wall in this sex, together with the smaller capacity of the pelvis. In one of my patients the final acute attack which brought him to operation resulted from the exertion of mowing his lawn, followed by an aperient which was necessitated by several days' constipation.

Diet may have some effect, and it is said that a vegetarian diet, with its large residue, is liable to produce volvulus. Possibly this factor accounts to some extent for the geographical distribution of the condition.

## CLINICAL SYMPTOMS.

The usual mental picture of forms of volvulus is that of an extremely acute intestinal obstruction with rapid and excessive distension of the abdomen and early onset of peritonitis. This is the description which is presented in Keen's *System of Surgery*, and also by Treves and Barnard, though both the latter writers comment on the fact that vomiting is an inconspicuous feature at the onset and may be entirely absent. Both these writers state that visible peristalsis is very rarely seen.

While there can be no doubt that the final attack which leads to operation or death is of this type, it is becoming increasingly recognized that long before this takes place there may be symptoms of a more chronic and recurrent type. Fernström<sup>1</sup> discusses this aspect of the condition very thoroughly, and differentiates clearly between acute and chronic forms. In many of the acute cases an investigation of the previous history will reveal the fact that the patient has suffered from vague colicky abdominal pain from time to time, often associated with diarrhoea and offensive stools. The attacks are often terminated by the passage of a large quantity of flatus or a very large stool. In one of my patients, a man of 52 years, there was history, dating back six months, of attacks of abdominal colic with constipation. These were usually brought to a end by a dose of salts, which produced a copious evacuation of motion and flatus.

The chronic symptoms, which are probably due to slight twists rectified spontaneously, therefore resolve themselves

into attacks of abdominal colic coinciding with constipation, followed by relief with a copious stool and the passage of a large quantity of flatus. Any one of these attacks may terminate in an acute volvulus, and it seems probable that the determining factor is the circulation in the affected loop. So long as the twist is not sufficient to interfere with this there is a chance of spontaneous untwisting. The importance of this factor is illustrated by the varying way in which an acute attack supervenes. In most cases the onset is quick, but in some it is much more gradual.

Many years ago I had under my care in the Booth Hall Infirmary a mentally deficient man, aged 35 years. My attention was called to him by the attendant because he was complaining of abdominal pain. I found him not urgently ill, with a moderately distended abdomen and very evident visible peristalsis of the large bowel type all over the abdomen. His condition was not serious, and I watched him for some days before I operated. At operation there was an enormous volvulus of the sigmoid without any strangulation, and I successfully excised the sigmoid loop in two stages by Mikulicz's method. Visible peristalsis was also a well-marked feature in the case I mentioned previously.

That the progress of the final attack may be slow when strangulation is absent is also supported by the case of a mentally deficient male, aged 22 years, reported by Edward Milton Foote.<sup>2</sup> The first symptom was abdominal distension, noticed by an orderly, and operation was undertaken three days later because of increasing distension and visible peristalsis.

A much more striking example was recorded by Maurice Richardson.<sup>3</sup>

The patient, a man aged 47, congenitally deaf and dumb, had suffered from severe attacks of abdominal pain with constipation for five years. The attack which led to operation was precipitated by a dose of castor oil, and for a month after the onset there was no passage of motion. The abdominal distension gradually increased, until at the time of operation it was very great, and was accompanied by visible peristalsis. There was no vomiting. Although the attack had lasted so long there was no gangrene, but the affected loop was dark in colour. The bowel was aspirated, untwisted, and fixed in position. The volvulus recurred five months later, and was then resected successfully.

X-ray examination in patients suffering from symptoms of chronic volvulus may be of great value. A barium enema will show the greatly enlarged sigmoid loop. On two occasions I have operated in cases of this type and have successfully removed the sigmoid loop. In one this resulted in a complete cure of the symptoms, but the other patient still suffers from constipation and abdominal pain.

#### TREATMENT.

The treatment of acute volvulus is entirely surgical. Little is to be gained by wasting time with enemata, and purgatives only make conditions worse. When the loop is viable it is often possible to evacuate it by a tube pushed up from the anus guided by a hand in the abdomen. The twist is then easily undone, and, so far as that attack is concerned, the patient is cured. Many attempts have been made to prevent future twists by fixing the sigmoid to the abdominal wall or by plecting the mesentery. All of these are liable to be followed by recurrence. Indeed, one might almost say that recurrence is the rule.

There can be no doubt that the ideal treatment is resection of the sigmoid loop. This is always essential when the bowel is too damaged to recover, and I believe it is the right treatment in all cases. I have employed it in all four acute cases I have had to deal with. One patient, with a gangrenous sigmoid, died from prolapse of the small gut alongside the double-ended colostomy I had made. This happened on the fifth day, and up to that time the patient had been very well. The accident was certainly due to an error in technique. The other three patients, in all of whom gangrene was absent, recovered. The method I adopted in all four cases was immediate resection of the affected loop with a double-ended colostomy. Later an end-to-end anastomosis was made in two of these patients. The third saved me the trouble by re-establishing her intestinal canal spontaneously. This two-stage operation has seemed to me to be safer than an immediate end-to-end union. There is no doubt that immediate anastomosis gives a much cleaner and pleasanter result, and it may be, as Mr. Morley points out, that there is not the same accumulation and distension in the colon

above the volvulus as there is in cases of carcinomatous obstruction, and therefore not the same risk with immediate anastomosis as there is in these latter cases.

Finally, it is sometimes possible to recognize the presence of intermittent symptoms from chronic volvulus. When this is so, and the diagnosis is confirmed by the x-ray appearances, it seems justifiable to excise the sigmoid loop, as I have done on two occasions.

## THE PRESERVATION OF YELLOW FEVER VIRUS

BY

A. W. SELLARDS,

DEPARTMENT OF TROPICAL MEDICINE, HARVARD MEDICAL SCHOOL,  
AND

EDWARD HINDLE,

REIT-MEMORIAL RESEARCH FELLOW IN TROPICAL MEDICINE.  
(From the Wellcome Bureau of Scientific Research.)

THE study of yellow fever has recently been greatly facilitated by the important discovery (Stokes, Bauer, and Hudson, 1928) that the common rhesus monkey (*Macacus rhesus*) is very susceptible to this infection. Hitherto the necessity of using human volunteers for any experiments has prevented a very systematic study of the disease, and therefore the value of this discovery cannot be overestimated.

Unfortunately the cost of sending monkeys from India to the West Coast of Africa, and the transportation in Europe, is very considerable, as the double journey involves a very high mortality. One of us (A. W. S.) found the mortality of monkeys sent to West Africa was such that their average cost came to nearly four times that in London. Apart from financial considerations, the study of the yellow fever virus can be conducted far more readily in countries where the natural carrier of the infection is absent. Experiments in localities where *Aedes aegypti* may be present involve keeping all infected animals under mosquito netting to prevent the chance of their being bitten by any mosquito and possibly starting an epidemic. Consequently infected monkeys in such localities are always a potential source of danger to the community and involve continual attention. In temperate countries these difficulties do not arise, as even in the presence of *Aedes* the temperature conditions are such that the mosquitos could never become infective. The development of the virus in the intermediate host is extremely slow and uncertain at a temperature of 22° C., and the optimum temperature seems to be in the neighbourhood of 28° C. Consequently the disease is restricted definitely to countries where such conditions prevail, and has never become endemic in temperate zones.

Hitherto the study of the disease has been confined to the regions in which it occurs, unlike the majority of human infections, which can now be investigated in the main laboratories of Europe and America, for although the French Yellow Fever Commission (Marchoux, Salimbeni, and Simond), 1903, carried infected mosquitos back to Paris from Brazil, no method of maintaining the virus was then known.

Considering the evidence in support of the view that yellow fever is caused by a filterable virus, it seemed of interest to see whether the virus could maintain its vitality when frozen, in the same way as many other filterable viruses, and accordingly an attempt was made to transport infected material in this manner.

The strain of virus employed was isolated from a case of yellow fever in a young Syrian at Dakar (Mathis, Sellards, and Laigret, 1928). This patient suffered from a mild attack, characterized by two febrile periods separated by a short intermission. The conjunctivae were slightly jaundiced and congested, and the urine contained a trace of albumin. On the seventh day of the disease, just before convalescence, the patient showed signs of collapse, with marked cardiac symptoms. Twenty hours after the commencement of the fever sixteen mosquitos (*Aedes*

(aegypti) were fed on the patient, and at the same time 4 c.cm. of blood were collected and inoculated into a rhesus monkey. Two days later this animal had a slight fever and was found dead on the eighth day after the inoculation. At the necropsy a slight jaundice was observed, and also lesions resembling those of yellow fever. The blood and a suspension of liver were inoculated into two young guinea-pigs, which remained healthy, thus excluding the presence of *Leptospira icteroides*.

Twenty-four days after feeding on the patient the mosquitoes were allowed to feed on a rhesus monkey, which showed a sharp rise in temperature after an incubation period of three days, and succumbed to a typical attack of yellow fever two and a half days later. Another monkey was also infected by this same batch of mosquitoes.

This strain was maintained in monkeys, either by the bites of infected mosquitoes or by direct passage, for a period of nearly three months, all the animals showing the characteristic symptoms of the disease. Shortly before leaving Africa one of these monkeys was killed at the height of the infection, and some of its blood, and also pieces of liver, were collected in sterile tubes, which were then carefully sealed to exclude air, and at once frozen in a mixture of ice and salt. The sealed tubes, in metal containers, were kept frozen during the journey to London—a period of twelve days—and on arrival were inoculated into two rhesus monkeys.

The first monkey, inoculated with an emulsion of the liver, showed a rise of temperature after an incubation period of four days, and was found dead on the morning of the seventh day. Its temperature chart (Fig. 1) is reproduced herewith, and

FIG. 1.—Temperature chart of rhesus monkey inoculated with a suspension of frozen liver from a case of yellow fever. The animal was found dead on the morning of the eighth day.

it will be noticed that on the day preceding death the temperature was subnormal, a common feature of the disease in monkeys. On the last day of the disease the animal showed symptoms of jaundice, which were particularly well marked in the ears and face. At necropsy the subcutaneous fat, and especially that around the pericardium, was intensely yellow. The liver was mottled and pale, and showed marked signs of fatty degeneration. The stomach contained a quantity of the characteristic coffee ground material.

The second monkey was inoculated intraperitoneally with the frozen blood, and as it showed no rise of temperature on the fourth day it was reinoculated with infected liver material from another monkey. The following day it showed a rise in temperature, but in view of the subsequent course of the disease, as shown in the accompanying chart (Fig. 2), it is

FIG. 2.—Temperature chart of rhesus monkey inoculated with frozen blood from a case of yellow fever, and reinoculated on the fifth day with infected liver material. The animal was killed on the tenth day.

somewhat doubtful whether this first rise was the result of the blood inoculation or not. Four days after being inoculated with the infected liver emulsion the temperature showed a distinct rise, which continued the following day, when the animal was killed. At necropsy the only obvious features of the disease were slight jaundice in the subcutaneous fat, fatty degeneration of the liver, and slight inflammation of the lining of the stomach. Subinoculation into another monkey, however, produced a typical and fatal attack of yellow fever. Cultures for *Leptospira* on Noguchi-Wenyon medium, blood agar slopes, and Fletcher's medium, all gave negative results.

It is evident, therefore, that the yellow fever virus can maintain its virulence when frozen for at least twelve days, and possibly much longer, a property which will be of considerable assistance in preserving the virus and further studies on the nature of the infection.

We should like to express our thanks to Dr. C. M. Wenyon, F.R.S., for providing us with accommodation, and also for much valuable assistance.

## A FATAL CASE OF POISONING BY A NON-ARSENICAL WEED-KILLER.

BY

A. H. D. SMITH, M.C., M.B., CH.B.ED.,

HONORARY SURGEON AND RADIOLOGIST, LEANLEY GENERAL HOSPITAL.

IN the following case of poisoning by a weed-killer the effects were so profound and so rapidly fatal that an account of the clinical course would seem to be of general interest. The weed-killer taken consisted of 75 per cent. tar acids emulsified with soap; it was dark in colour, had a strong smell of tar, and formed a milky emulsion in water. The makers reported that both lysol and this weed-killer consisted of carbolic acid, soap, and water, lysol containing 50 per cent. and the weed-killer 75 per cent. carbolic acid, while the proportion of soap in lysol was larger. They also stated that the symptoms of poisoning produced by the weed-killer would be similar to those of carbolic acid or lysol poisoning.

Commercial cresylic acid, so-called liquid carbolic acid, consists of 35 per cent. orthocresol, 40 per cent. metacresol, and 25 per cent. paracresol. The effects produced by the cresols are identical with those of phenol; metacresol is the least poisonous, and paracresol the most poisonous (see *British Pharmaceutical Codex*, p. 369). In cases of poisoning by cresol the treatment for carbolic acid should be employed (*ibid.*, p. 370). Taylor, in *Medical Jurisprudence*, describes as comparatively innocuous a substance consisting of 20 per cent. cresylic acid with neutral hydrocarbon oil and resin soap; it is a dark-coloured liquid, mildly antiseptic. One instance of poisoning by it is reported in detail by Dr. Pinner, who states that the effects are not fatal.

The clinical details of the case are as follows.

The maximum amount which could have been swallowed was just over 2 fluid ounces (56.763 grams). To test the accuracy of this statement the average contents of a series of unopened tins were compared with the contents of the tin from which the poison had been taken. The patient, a well-built man, aged 32, had always enjoyed fairly good health, but had recently been greatly worried by the death of his wife. Somewhere about 10 a.m. on August 21st, 1927, he took the poison, and about 10.40 a neighbour found him lying in bed; he was groaning, but quite conscious, and refused a cup of tea. He did not complain of pain and had not vomited. When I saw him, at 11 a.m., he was comatose; there was no corneal reflex and his breathing was stertorous. He was markedly cyanosed, and his pulse was fast and almost imperceptible. His skin was cold and clammy, and he was sweating profusely. In his breath a strong smell of tar was detected, similar to that of a liquid contained in a glass by his side and in a tin of weed-killer also in the room. Careful examination revealed no sign of corrosion of the lips, tongue, mouth, or pharynx.

He was removed to hospital, and about 11.20 was receiving treatment. The stomach was washed out, and the returning fluid, milky in appearance, had a strong smell of tar; it contained no foodstuffs. After repeated wash-outs white of egg was put into the stomach, and in view of his cyanotic condition oxygen was given; atropine sulphate was also injected hypodermically. He rapidly went downhill and died about 11.40 without regaining consciousness. There were no signs of corrosion of the lips, mouth, tongue, or pharynx.

The necropsy revealed no signs of any abnormality save an old pleurisy in the left side. The stomach and oesophagus were removed and the contents sent for analytical examination. Careful examination of both stomach and oesophagus showed not the slightest sign of corrosion or excretion. The stomach contained no food, only some turbid fluid with a strong smell of tar.

The report of the analyst stated:

"The contents of the stomach smelt of phenols or tar acids and the distillate gave a strong reaction for them. No cyanides

or hydrocyanic acid were present. No mercury, lead, copper, arsenic, or tin were present. No alkaloidal poison could be detected."

In view of the assertion by Pinner as to the relative harmlessness of cresylic acid, and of the statement of the makers of the weed-killer that the toxic action of this substance would be similar to that of carbolic acid and lysol, it seems that in this case, at all events, the toxic effects were not those usually seen in a case of carbolic or lysol poisoning. The symptoms were those of a poison acting on the nervous system—the so-called narcotic action of carbolic acid and its homologues—and this action was probably due to the paracresol. It is evident that emulsified preparations of the tar acids (carbolic homologues) are not necessarily corrosive; if a 75 per cent. emulsion is tested on the lip or tongue the effect is simply a temporary smarting, whereas carbolic or lysol produces burns on even hard skin.

#### Conclusions.

My object in reporting this case is threefold:

1. To show that cresol or cresylic acid is not the innocuous substance described by Pinner, at all events when taken in a concentrated form as an emulsion on an empty stomach. Under these conditions, when the toxic cresols are present, the rapid absorption of the poison by the stomach has a profound and fatal effect on the nervous system.
2. To suggest that a substance which can have so rapid and fatal a result should be included in either Part 1 or Part 2 of the Schedule of Poisons. At present it can be sold over the counter by any person, provided it is contained in a closed vessel distinctly labelled poisonous, with the name and address of the seller and a notice of the special purpose for which it is intended.
3. To urge that more attention should be paid in textbooks to the toxic action of the cresols on the nervous system. Attention seems to be focused mainly on the corrosive action. This is true of carbolic acid, and of lysol to a lesser degree, but when we deal with the cresols (cresylic acid), the corrosive action is negligible, while the toxic effects on the nervous system are profound.

### ERYTHEMA NODOSUM AND ACUTE ENDOCARDITIS FOLLOWING TONSILLITIS:

RECOVERY AFTER TREATMENT WITH ANTISTREPTOCOCCUS  
SERUM.

BY

A. MARKSON, M.B., CH.B.,  
LIVERPOOL.

THE following case seems of sufficient clinical interest to record.

On January 20th I was called to see a girl, aged 22, suffering from acute follicular tonsillitis. A swab taken for diphtheria proved negative, and the patient was given a sodium salicylate mixture. Defervescence with amelioration of symptoms occurred, and by the fifth day the temperature was normal and the throat much better. The next morning, however, the patient was worse, and the temperature had risen abruptly to 102° F. The face was flushed, she was sweating profusely, and she complained of painful spots on the legs, pains in her joints, dyspnoea, and palpitation on moving. Examination of the legs revealed a crop of large, roundish, raised, tense swellings, of the whole thickness of the skin, along the anterior borders of both tibiae. Bright red, glossy, and extremely tender to the touch, they presented the typical eruption of erythema nodosum. The right knee, right ankle, and left wrist were painful, but not swollen. The precordial impulse was increased, the first sound at the apex was roughened, and the second pulmonary sound accentuated. I recalled the association of erythema nodosum with true rheumatism, and accordingly increased the salicylate dose to 20 grains every three hours, combined with sodium bicarbonate. A sedative lotion was also prescribed for the legs. The urine was febrile, and contained a little albumin. During the next few days the temperature ranged between 101° and 103.6° F., and fresh crops of erythematous swellings kept appearing on the legs and thighs. There was now at the apex a soft, blowing, systolic murmur, conducted into the axilla, the second pulmonary sound remained definitely accentuated, and an appreciable increase in the transverse area of cardiac dullness could be detected. There were no rigors, the spleen was not enlarged, and the lungs were clear. Severe pain continued in the joints, and now affected also those of the fingers of both hands, but no arthritis developed. The

salicylates, however, did not influence the temperature nor relieve the joint pains.

On the fifth day following the onset of the erythema nodosum and the endocarditis the patient was still very ill, with no sign of improvement. The temperature was 103° F., and the pulse 120; she was still dyspnoeic, and a fresh crop of swellings had appeared that morning on the right leg. That afternoon I injected 25 c.cm. of polyvalent antistreptococcus serum well under the skin of the flank. The result was almost dramatic. By the next morning the temperature had dropped to 99.6° F., and the pulse to 90; the joint pains had gone, the tension in the erythematous swellings was relieved, and the dyspnoea was much better. From that day no fresh crops of erythema nodosum appeared, and those already present, even the new ones of the previous day, disappeared in five days. On the third day after the injection some peritonsillar inflammation developed (until then the throat had been much better), and the temperature rose from 98.8° to 100° F. I injected a further 10 c.cm. of the serum, and twelve hours later the throat had improved and the temperature was normal. The temperature and pulse have now remained normal for a fortnight, no acute symptoms have recurred, and the girl feels much better. At the time of writing she is being kept in bed a little longer for her mitral condition.

I am aware that the connexion of erythema nodosum with rheumatism, although long debated, is not proved, but there were justifiable grounds in this case for associating the two conditions—namely, the initial tonsillitis, the joint pains, and the endocarditis. In spite of this, however, large doses of the salicylate had no effect. It is well known that tonsillitis can be an etiological factor in acute endocarditis, and, judging from the remarkable effect of the antistreptococcus serum in this case, it is possible that the tonsillitis ushered in a train of streptococcal developments, producing not only the endocarditis, but also the erythema nodosum. The etiology of the latter is still not decided, although Rosenow claims to have isolated a bacillus with coccoid forms. I am convinced that the serum had a decided beneficial effect on the erythema nodosum in my case, and, this being so, there may be here a point of etiological significance in connexion with his theory.

#### DIAGNOSIS OF "PLEURAL SHOCK" FROM COCAINE POISONING.

THE differential diagnosis of acute cocaine poisoning and "pleural shock" may be a very difficult matter, as the following report of a case shows.

A dental mechanic was readmitted to Winsley Sanatorium on March 16th, 1928, and, owing to constant bleeding, it was decided to perform artificial pneumothorax, though this was not otherwise required. I ordered a 1/4 grain of morphine to be injected half an hour before the operation, and the patient seemed unduly anxious to know what drug had been employed. When I came for the operation he asked me what local anaesthetic was used, and I told him epinephrine, each cubic centimetre of which contains epinephrine 0.0005 gram, and cocaine hydrochloride 0.02 gram. I thought the question a professional one and treated it as such. He made no comment. The injection of 1 c.cm. was given with the usual small syringe with its corresponding needle, and I "felt" the pleura; since the patient was nervous I paid particular notice to the effect of this, but he did not feel the prick. Wishing to wait for five minutes and to take his mind off the artificial pneumothorax, I talked about the war, in which he had been gassed and had suffered from neurasthenia. He suddenly became faint, and cried out "I am going"; he was at first quite limp and looked like a corpse, then there followed a spasm, the face was drawn to one side with marked stiffening of the left sterno-cleido-mastoid muscle, reminding me of the classical picture of torticollis in the textbooks. The teeth were clenched and grinding, the respirations rapid, the pulse could not be felt at the wrists, and there were only very feeble indistinct heart sounds. I thought the condition was delayed pleural shock. I administered strychnine grain 1/60 on empirical grounds, and after half an hour the whole attack was over. In the afternoon he was much better and told me he had an idiosyncrasy to cocaine; this I verified subsequently.

In his introduction to *Forensic Medicine* Dr. Burridge gives the symptoms of cocaine poisoning as—

"If a poisonous dose has been absorbed the person becomes pale, feels faint, and may fall to the ground. Convulsions followed by unconsciousness may occur. The pupils are dilated and insensible to light. The pulse may be uncountable at first. On recovery the patient complains of diminished sensibility of the hands, etc. In several cases epileptiform convulsions have occurred, followed by death in a few minutes";

and Dr. Clive Rivière the symptoms of pleural shock as—

"The symptoms have appeared as a rule with great suddenness at the moment when the needle is entering or leaving the pleural space. More rarely they come on after an interval of fifteen to twenty minutes, or even after some hours. In a typical case the patient develops a sudden pallor, loses consciousness, and soon becomes cyanosed. The pulse and respiration become irregular, the pupil large, and clonic and tonic spasms of the limbs ensue, or these occur only on the side of the pleural reflex or in isolated muscles. Some patients cry out at the onset."

This indicates the lines of differentiation. There was obviously no question of gas embolus.

Unless the bleeding is excessive I shall not again try to induce an artificial pneumothorax in this patient, and I shall not use a local anaesthetic. I have seen slight pleural shocks in other cases, and a very slight cocaine attack on one occasion. I should appreciate the opinion of experts.

Sanatorium, near Bath.

### OMENTAL CYST IN AN INGUINAL HERNIA.

THE following case seems worthy of record for its interest in regard to diagnosis.

A swelling of the left side of the scrotum about the size of a walnut appeared in an infant 6 weeks old. The swelling gradually increased in size, but had remained always easily and completely reducible until three weeks before his admission to hospital at the age of 1½ years. The child was then playing on the floor when he screamed suddenly and was unable to get up by himself. The mother noticed a slight fullness in the left groin immediately above the swollen scrotum, and found that she could not now reduce the scrotal swelling. From that time until admission the fullness of the groin continued, but did not increase in size, and the mother was able to reduce the scrotal swelling only slightly. The bowels had been regular. The smooth oval swelling was about the size of a small coconut; it was fluctuant, translucent, and dull on percussion; the scrotal skin moved freely over the swelling. It was easily collapsible on pressure, being reducible by about two-thirds. There was a little increase in the size and tension of the swelling on straining, and the slight fullness of left groin immediately above the scrotum was not reducible.

**Diagnosis.**—The obvious collection of fluid in the scrotum suggests abdomen. Its ready reducibility into the patent form suggested the presence of fluid in a ns is sometimes seen in the ascitic or in ascites from other causes, but there was no nodular thickening of the tunica vaginalis detectable, nor was there any general abdominal swelling or shifting dullness in the flanks.

**Operation.**—The left inguinal canal was opened through a left inguinal incision, and the spermatic cord appeared to be more bulky than normal. On incising the large hernial sac a second sac was found within it containing clear dark, yellowish fluid. This sac was readily drawn up into the wound from the scrotum, and, downward traction being made upon it, the walls of the sac were easily drawn down, sliding smoothly through the inguinal incision, and the contained fluid continued to gush downwards from within the abdomen. Traction was continued until the whole sac had been delivered from the abdomen; it was roughly the size of a large coconut, and contained 15 to 20 ounces of fluid. There was a smaller sac, loculated from the main sac in its upper right part, which contained about 2½ ounces of fluid. A small accessory spleen was present on the left wall of the sac near its upper limit. On further investigation of the relations of the large cyst which had thus been delivered through the hernial sac, it was found to be an omental cyst arising from the left border of the great omentum, the lower portion of which had formed the sole contents of the patent, greatly distended processus vaginalis. The cyst was tied and removed by its pedicle at its emergence from the abdominal cavity; the peritoneal hernial sac was also transfixed, tied, and removed, and the gap closed by stitching the conjoint tendon to Poupart's ligament in front of the spermatic cord. The child made an uninterrupted recovery.

I am indebted to Mr. Morley, who operated on the patient, for permission to publish these notes.

Children's Department,  
St. Mary's Hospital, Manchester.

FANNY HOWE, M.B., Ch.B.

### SCARLET FEVER: REINFECTION FROM EMPYEMA.

THE following case, in which the patient had two distinct attacks of scarlet fever within three months, seems worthy of record.

A boy, aged 6 years, was admitted to hospital on November 8th, 1927, with typical scarlatina of septic type, accompanied by marked dyspnoea. There was a history of six days' previous illness. On admission he had a very marked scarlatinal rash with severe sore throat and typical tongue. Temperature 102° F., pulse 146,

respirations 44. He was given 500,000 units of scarlatinal anti-streptococcus serum. There was marked dullness over the back of the right lower lobe extending to the mid-axillary line, marked dyspnoea, and slight cough. Four ounces of semi-purulent fluid were withdrawn. A further aspiration was attempted the next day without result. Meanwhile, the patient had become cyanosed the rash was not fading, and sores were appearing around the mouth and nares. A further 500,000 units of serum were given. By November 11th the dullness was quite "stonewall," and bronchial breathing was heard in the upper lobe. Streptococci were found in the effusion which had been removed. The rash faded on November 12th. On the following day a further five ounces of definite pus were removed from the chest, and thoracotomy was decided upon. A left otorrhoea made its appearance. Resection of a rib freed a large quantity of sero-purulent discharge. Desquamation commenced on November 17th. By this time the patient had become very septic; the pneumonia had cleared up, but he was obviously only just holding his own. Hypodermic injections of camphor in oil and rectal injections of glucose were resorted to.

A temporary improvement in the general condition began on November 21st, but was checked two days later by the appearance of enlarged cervical glands on both sides with increase of nasal and nasal discharge. About this time the empyema cavity showed evidence of "pocketing," and irrigation with enol was tried.

It was not until December 5th that any marked improvement took place, but by the end of the month the boy was well enough to run about the grounds on fine days. There was a slight bead of discharge from the sinus on the dressing each morning.

On February 1st the boy complained of sore throat and vomited three times. The temperature went up to 102° F., and a typical scarlatinal rash developed by evening, with slight pharyngitis and a strawberry tongue. A sudden increase of thin watery discharge from the empyema sinus was noticed, and in this discharge were found staphylococcus aureus and haemolytic streptococci. The amount of discharge increased until February 6th, and by the 28th haemolytic streptococci were absent. The rash had gone by the 6th. Desquamation commenced on the 11th. The boy was discharged on March 9th perfectly well, with a small discharging sinus to be dressed by his private doctor.

In this case it would appear that the acquired immunity from the first attack was soon lost, and that the boy actually reinfected himself from the haemolytic streptococci in his own empyema.

HERBERT E. MARSDEN, M.B., D.P.H.,  
Medical Officer of Health, West Lancashire  
Rural District.

### RENAL ABSCESS FOLLOWING GONORRHOEA.

THE occurrence of renal abscess as a complication of gonorrhoea is sufficiently rare to justify the publication of the following note of a case.

A sailor, aged 19, was admitted to the British Military Hospital, Shanghai, on February 2nd, with a purulent urethral discharge containing gonococci. He was put to bed on milk diet, and given irrigations of potassium permanganate (1 in 8,000) twice daily. Eight days later he had a temperature of 99.4° F., and complained of pain in the left lumbar region. His urine was acid and contained much pus with intracellular gonococci, no other organisms being seen. He was given urotropine in 10-grain doses three times a day. On February 19th he was given an injection of 1,000 million gonococci, with little or no reaction. Further injections of 2,000 million and 3,000 million were given on February 22nd and 24th, with almost similarly negative results. Bladder irrigation with 1 in 8,000 oxymercure of mercury was also prescribed. Pyrexia continued in the region of 101° F. On February 25th a swelling was found in the left lumbar region, with pain and rigidity on pressure. A diagnosis of renal abscess was made and the patient transferred to the General Hospital, where facilities for operation were available.

On March 3rd, under ether anaesthesia, the usual kidney incision was made. This exposed to view a large fluctuating kidney, from which about a quart of cream-coloured pus was evacuated. A large rubber drain was inserted and the wound was closed.

Bacteriological examination of the pus revealed gonococci, and cultivation on blood agar remained sterile, indicating the absence of secondary infection.

The patient's temperature returned to normal within two days, and convalescence was uneventful. Vaccines and urethral irrigations were again employed.

This case merits attention, I think, from three aspects: (1) the rarity of renal abscess as a complication of gonorrhoea; (2) the absence of secondary infection; (3) the question of the pathology. Did the infection reach the kidney by way of the lymphatics, or were the ureteric valves rendered so incompetent by the cystitis as to allow the gonococcus admission that way?

For permission to publish this case I am indebted to Colonel S. Pallant, R.A.M.C., and Dr. F. M. Neild (Admiralty surgeon and agent).

J. K. G. WAX, M.R.C.S., L.R.C.P.,  
Shanghai. Surgeon Lieutenant, R.N.

## Reports of Societies.

### BASAL METABOLISM.

At a meeting of the Aberdeen Medico-Chirurgical Society on April 5th, the president, Dr. THOMAS FRASER, in the chair, a paper was read by Dr. ALEXANDER LYALL on basal metabolism in clinical medicine.

Dr. Lyall indicated that estimation of basal metabolism had been of great value to the physiologist in the investigation of nutritional problems long before any use had been made of the method clinically. He outlined the methods in use for the estimation of basal metabolism, referring shortly to the method of direct calorimetry, which, he said, was too complicated for clinical work, and proceeded to a description of the method in general use where the basal metabolic rate could be calculated from the collection of expired air under standard conditions. The patient had to be perfectly at rest mentally and physically, and post-absorptive—that is, having taken no food for fifteen hours previously. The data necessary were the height and weight of the patient, the total volume of expired air over a known experimental period, the respiratory quotient, and oxygen consumption during the time of estimation. Under suitable conditions uniformity of results was achieved by this method. In one mild case of exophthalmic goitre, where the estimation had been carried out four times at three-monthly periods, the oxygen consumption on these occasions had been 254 c.c.m., 251 c.c.m., 255 c.c.m., and 258 c.c.m. per minute, with the respiratory quotient about 0.82 on each occasion. Dr. Lyall pointed out that the experimental error in the method was about *plus* or *minus* 8 per cent., but he believed the error tended always to be towards the upper side. Thus a basal metabolic rate of *plus* 10 per cent. was within normal limits, but a basal metabolic rate of *minus* 5 per cent. showed a degree of reduction upon which one was entitled to place diagnostic importance. A series of 45 cases of exophthalmic goitre had been investigated once or repeatedly by this method. The basal metabolic rate was increased from 15 to 50 per cent. in 14 cases, from 50 to 60 per cent. in 22 cases, and to above 60 per cent. over normal in 9 cases. The highest rates were *plus* 87 per cent., *plus* 97 per cent., *plus* 100 per cent., and *plus* 105 per cent. Three of these four severe cases had auricular fibrillation. The patient with the highest rate was a typical case of the fulminant type of the disease. Generally speaking, the group of cases classed as mild by estimation of basal metabolism were those likely to become good civil lives within a reasonably short period of medical treatment alone. The cases in the group of moderate severity were likely to stand operation well if there was no other contraindication. The group with basal rates above *plus* 60 per cent. made poor surgical risks. The speaker enumerated the additional factors which should be taken into account in considering the operative risk: (1) There should be no organic heart disease; (2) the blood urea should be below 50 mg. per 100 c.c.m.; (3) the patient should have already regained half the previous loss in weight; (4) the blood pressure should not vary further from normal than 140 mm. Hg systolic and 70 mm. Hg diastolic; (5) the patient should have already regained self-control in fair measure. In nine of the cases in which glucose tolerance tests had been carried out the blood sugar curves showed inability to deal properly with glucose. The condition should not be confused with true diabetes, although in this series three cases of diabetes mellitus occurred. Eleven cases of myxoedema were investigated, the basal metabolic rate varying from *minus* 3 per cent. to *minus* 42 per cent., the average reduction being 14 per cent. In four of these cases previous exophthalmic goitre had been present, and the time factor in the change from hyperthyroidic symptoms to hypothyroidic was discussed. A series of cases of toxic adenoma of the thyroid and simple adenoma had shown that the basal metabolic rate was raised in the former group of cases, but not in the latter. In puberty goitre the basal metabolic rate was not increased. The estimation had not been found of value in the diagnosis of malignancy of the thyroid gland. In summing up

shortly Dr. Lyall said that the estimation of basal metabolism was of value in the diagnosis of the less pronounced degrees of thyroid dysfunction. In his opinion it would give help in prognosis and indicate the line of treatment in established cases, and would be of value in the control of treatment, especially by x rays.

### DYSPIUITARISM.

At a meeting of the Section of Neurology of the Royal Society of Medicine, held on April 19th at the West End Hospital for Diseases of the Nervous System, Drs. C. WORTER-DROUGHT and B. W. CROWHURST ANCHER showed jointly a case of dyspituitarism occurring in a boy, aged 15.

The patient, who was normal at birth, was said to have begun to sit up and cut his teeth at the usual ages, but did not walk until nearly 3 years old. After this he increased rapidly in stature, and became much fatter than the average child of his age. He went to school at the age of 5, but made no progress; he never learned to read or write, but showed some interest in mechanical things. His general behaviour was always good. During the last year he had been unable to get about very well, owing to weakness of the legs. The appetite was always very large, and the boy was unusually fond of sweets. Thirst was within normal limits. Though there were frequent attacks of vomiting at night, sleep was fairly good; there was no trouble with headaches, and the sight and hearing were normal. Sexual development was late. His present height was over six feet, and his weight 19st. 8lb. There was pronounced general obesity with fairly uniform distribution of the fat. There was slight differentiation of the shoulder and pelvic girdles, but no padding in the supraclavicular regions or on the dorsum of the hands. The hair in the pubic region was scanty and conformed to the male distribution. The skin was normal in texture, and covered with a slight growth of fine hair. Muscular power was relatively weak. The forehead was full and prominent, the jaws large, the palate arched, and the upper teeth projected beyond the lower. The temperature was invariably subnormal and the pulse rate averaged 90; the functions of all the cranial nerves were normal, and there were no disturbances of sensation or co-ordination. The motor power in the upper limbs was fair, but below normal. The two hands were constantly held together in a position of flexion at the wrist, full extension at the metacarpo-phalangeal joints, hyperextension at the interphalangeal joints, and approximation of the tips of the fingers to each other. The lower limbs appeared to be normal, except that in standing the knees were held close together and the feet were separated. The abdominal reflexes were brisk and equal, and the other reflexes normal. The gait was slow and awkward, with the knees close together, and the feet separated. At an x-ray examination the sella turcica was found to be rather small, but scarcely outside the normal limits. The frontal sinuses were unusually large and the lower jaws big and prominent. The epiphyses of the wrist were normal, but those of the fingers had united. It was added that the mental age of the boy, according to the Stanford modification of the Binet-Simon scale, was between 6 and 8, though for questions involving simple matters of conduct it might be placed at the higher of the two levels. His intelligence quotient was about fifty.

### Charcot's Arthropathy of Both Wrists.

Dr. Worter-Drought also showed a case of Charcot's arthropathy of both wrists occurring in a painter, aged 50, who had complained of swelling of the right wrist since 1918. The onset was gradual without pain, and about a year later the left wrist became slightly affected. The clinical details were as follows.

The right wrist was irregularly enlarged and much deformed. On the dorsum, towards the ulnar side, there was a large swelling containing some fluid with bony thickening beneath; a similar, but smaller, swelling was situated on the radial side of the joint. The enlargements were not painful or tender. Flexion and lateral movement at the joint was moderate, and extension was very limited. X-ray examination showed total disorganization of the joint, the carpus having almost entirely disappeared, the lower ends of the radius and ulna being dislocated dorsally on the bases of the metacarpal bones. The left wrist was considerably swollen, especially towards the ulnar side, and was deformed. An x-ray photograph showed an early stage of Charcot's arthropathy, with little bone damage. The metacarpo-phalangeal joints of the left index and middle finger were also swollen and enlarged, but freely movable. The right pupil was larger than the left, and neither reacted to light, though each responded to accommodation-convergence tests. The other cranial nerves were normal. There was some ulnar and tendo-Achillis analgesia; the knee-jerks were present, the right being slightly brisker than the left; arm-jerks, abdominal reflexes, and ankle-jerks were normal; the plantar response was flexor, and no definite inco-ordination was detected. There was no history of syphilis, but the Wassermann reaction was positive, and the colloidal gold test showed a curve of the luetic type.

Dr. Worter-Drought said that during the past three years the patient had been treated with courses of novarsenobillon intravenously and bismuth intramuscularly. The neurological signs at the right wrist and metacarpo-phalangeal joints had remained unaltered, but the left wrist had slowly become worse.

## Rebels.

### HEREDITY.

To those who were young in the days of the Homeric battles of the Mendelians and biometricians, the perusal of such a straightforward and impartial account of the present state of opinion as Dr. Crew's *Organic Inheritance in Man*<sup>1</sup> is particularly interesting. The smoke of the battle has long ago been dissipated, and, alas! the two protagonists, Bateson and Weldon, are gone. Like most issues hotly contested between scientific men of genius, the decision has not been wholly in favour of either. If, like a boxing match, a decision were to be given "on points," no doubt the Mendelians would have it. Not only in intellectual suggestiveness, but even in the utilitarian field the investigations which sprang from the rediscovery of Mendel's work have been more fruitful than those which were promoted by the school which was at first directly hostile to the Mendelians. But it is not less true that in the field of human inheritance the splendid work of Karl Pearson and his pupils and associates—among whom the late Edward Nettleship was not the least—has demonstrated that the contempt of the earlier Mendelians for the methods of Galton and his followers was unwarranted. Dr. Crew is of opinion that the name of Thomas Hunt Morgan "will surely be added to those of the immortals of science. He does not merely stand on the shoulders of Mendel; seeing further, he has sprung therefrom to conquer a province of his own;" and a large part of this volume is devoted to an exposition of the work of Professor Morgan, based upon an intensive study of the fruit fly, *Drosophila melanogaster*.

Dr. Crew (whose book has grown out of a course of lectures intended for medical men) has taken considerable pains to make the subject clear, and has, we think, succeeded. The difficulties are of two kinds. In the first place, although geneticists often used to speak lightly of "mathematicians," to understand the possible numerical sortings-out of factors when the number of units is more than one or two really requires a grasp of the ideas of that particular branch of mathematics which rejoices in the formidable name of "combinatory analysis." In the second place, any visualization of the chromosome theory compels the reader to brush up his acquaintance with a part of cellular physiology that is not very easy to follow. Chapters II to IV of Dr. Crew's book will therefore make some demands upon the reader's attention. It might, perhaps, have been worth pointing out that the number of possible combinations of chromosomes in the zygote is the sum of the binomial coefficients (56 in the third line of the table is a misprint for 64) of  $(A+B)^n$ —that is,  $2^n$ —and to illustrate by symbolic multiplication, as well as by mere diagrams, how the frequencies of the various combinations are reached. The remaining chapters, dealing with co-sanguinity, inheritance in man, and disease resistance and immunity, are easier reading—the cynic will perhaps say because our detailed knowledge of these matters is so much less than what we know about the genetics of *Drosophila melanogaster*. But these chapters are very clearly and interestingly written, and contain very few instances of the dogmatism which is so common in writings upon human inheritance. We have only noted a few instances which struck us as in need of modification. We think that the remarks on the inheritance of left-handedness are too summary, and that the psychological complexity of this particular problem should be noticed. The remark that "the grandson of long-lived grandparents is by far the better 'risk' for an insurance company than is one of short-lived ancestry" is more dogmatic than any published evidence known to us warrants. Similarly, the statement that "there is no doubt that the principal determinant of longevity is heredity, and the average duration of life of a population cannot be modified at all profoundly by any sort of improvement in State medicine," is only true if we define the word "profoundly" in some special way.

These, however, and a few other similar dicta, do not detract from the general merit of the book, which we strongly recommend to the medical reader as a careful introduction to the subject.

The book is agreeably prefaced by a biography of the distinguished Birmingham physician William Withering, in whose honour the lectureship Dr. Crew held was founded.

### CHEMICAL PROPERTIES AND PHARMACOLOGICAL ACTION.

Drs. L. HUGONENQ and G. FLORENCE in their book *Principes de Pharmacodynamie*<sup>2</sup> have courageously attacked the difficult problem of the relation between chemical constitution and pharmacological action of drugs. The general purpose of the book is set out thus in the preface:

"The technique of physiological investigation is daily becoming more perfect; our knowledge of molecular architecture is continuously increasing and becoming more accurate; and finally, physical chemistry will doubtless bring forward all sorts of new conceptions which will illuminate the way. When all these synergic factors have produced their full effect pharmacodynamie will be a biological science, still developing, but based on solid foundations. The book is a miniature and imperfect representation of one of the first stages of this evolution, a period that is of the highest interest, as is the commencement of any subject which is destined to increase and perhaps, fated to play an important role. For, after all, surely the essential object of medical science is to relieve pain and, when possible, to heal the sick. It requires courage to pronounce this truth which is so often veiled from those workers, otherwise admirable, who are better equipped to describe than to fight disease."

The intentions of the authors deserve, therefore, the highest praise, but the task they have attempted is one of uncommon difficulty. Anyone who attempts to correlate chemical constitution and pharmacological action is faced with a vast mass of material of very varying accuracy. Here and there definite correlations occur between some structural or physico-chemical property of compounds and the intensity of the action that they produce on living tissues, but such correlations are exceptional cases scattered among innumerable unco-ordinated details.

Fränkel's *Arznei*<sup>3</sup> was noticed in our issue of May 14. It is a most exhaustive work on the subject. That encyclopaedic volume is an example of Teutonic industry, but it is essentially a work of reference, and gives no general view of the problems dealt with. The authors of the present work have kept their material within manageable limits and have produced a readable volume. They describe clearly important examples of drugs in which some recognizable connexion is apparent between chemical structure and pharmacological action. A few of the problems the authors deal with are as follows: Drugs acting on the various types of nerve endings—namely, sensory nerve endings, endings of medullated nerves and autonomic nerve endings, narcotics, antipyretics, and such specific remedies as the organic compounds of mercury, arsenic, antimony, and bismuth, and the antiseptic dyes.

The book is particularly interesting because it gives a fairly full account of the important researches in chemotherapy that have been carried out by French workers, of whom Fournieu is one of the best known. The significance of this work is apt to be overlooked, because the great majority of reference books are in German, and these tend to emphasize the work published in their own language. The volume concludes with two short but interesting chapters on war gases and anti-gas measures. The authors remark, however, that this information is out of date, because all the gases described have already been superseded by others whose composition is secret.

The authors deserve praise for their endeavour to give a coherent presentation of the difficult subject that they have chosen, but it cannot be said that they have succeeded in throwing much new light on the problems they discuss. The reason for this is that our present knowledge is unfortunately inadequate to permit of any important generalizations regarding the relation between chemical properties and pharmacological action.

<sup>2</sup> *Principes de Pharmacodynamie*. Par L. Hugoneng et G. Florence. Paris: Masson et Cie. 1928. (Med. 8vo, pp. viii + 391; illustrated. 40 fr. sans majoration.)

<sup>1</sup> *Organic Inheritance in Man*. By F. A. E. Crew, M.D., D.Sc., Ph.D. Edinburgh and London. Oliver and Boyd. 1927. (5½ x 9, pp. ix + 214; 37 figures, 1 plate. 12s. 6d. net.)

## THORACOSCOPY.

No doubt exists as to the value of endoscopy as applied to the bladder, stomach, and bronchial tubes, and it remains to be shown whether the method can be usefully applied to the pleura and peritoneal cavities. That it is feasible in the case of the pleura has been proved by Jacobaeus, who has successfully used it in his operation of division of pleural adhesions, and surgeons will welcome two excellent works on the subject—the *Atlas Thoracoscopicon*<sup>3</sup> of Dr. Felix Cova and the textbook and atlas of laparo- and thoracoscopy<sup>4</sup> by Dr. Roger Kohnsch—in which the technique of the method is described and the appearances seen in various diseases depicted.

Dr. Cova's work is purely an atlas, with brief explanatory notes on the illustrations. Of the latter it is impossible to speak too highly; the drawing and colouring are very fine, and the plates are sufficiently numerous—fifty in number—to give a good idea of the value of the method as an accessory means of diagnosis and in controlling operative procedures. Several plates exhibit the operation of Jacobaeus, and every detail of the procedure can be followed as if the operation were being conducted on the surface of the body. The descriptions of the plates (as well as the preface) are in Italian, German, and English.

Dr. Kohnsch's work has a different scope; it deals with the peritoneum as well as the pleura, and gives full details of the technique of the operations, their indications and complications, with fifteen coloured plates in illustration of the lesions; further, it enters into considerable detail relating to the pathological anatomy of the lesions brought into view, in their several stages. How far it will be considered justifiable to resort to laparoscopy as a substitute for exploratory laparotomy is at present doubtful; the former is the less serious operation, but the latter enables the organs to be handled as well as seen—a great advantage.

The two books referred to will assist the surgeon in forming an opinion on the possibilities of these new procedures.

## SANITARY LAW AND PRACTICE.

ROBERTSON and PORTER'S *Sanitary Law and Practice*<sup>5</sup> has in its sixth edition been added to, amended, and, where necessary, rewritten to keep pace with the changes of the last seven years. It now takes in the Sanitary Officers Order of 1926, the Memorandum on the duties of Medical Officers of Health of 1925, and the Public Health Smoke Abatement Act of 1926, which omits the word "black" as qualifying smoke in respect of which nuisance may be held to occur. It deals with the Public Health Act of 1925, and the various regulations as to meat and foods, including the Preservatives Regulations of 1925, which have come into operation since the fifth edition was published. The Tuberculosis Order of 1925 is likewise quoted. The Milk and Dairies Amendment Act of 1922, with the Act which it brought into operation, and relevant Orders, and the corresponding Acts and Orders for Scotland, are all duly set forth. The Housing Act of 1925 is presented and explained. The work in its present form contains sections on central and local health administration, on offensive trades and slaughter-houses, on the dairy by-laws, on infectious disease and its notification, and on tuberculosis. It treats competently of water supplies, sewage disposal, and housing. The subject of welfare is effectively presented, the mother, the infant, and the school child being dealt with in order. The concluding item is the Public Health Infectious Diseases Regulations of 1927. The work is therefore well up to date, and can once more be recommended to the student of public health as an ample and trustworthy guide.

## MEDICINE AS SHOWN IN ART.

Dr. CABANÈS has collected and published much material of an interesting and curious nature in connexion with the history of medicine and medical men; and out of his extensive store of knowledge has now brought to our notice the representations of disease in painting and sculpture in a copiously illustrated work entitled *Esculape chez les Artistes*.<sup>6</sup> Contesting the notion that science and art are incompatible, he recalls that great artists, such as Leonardo da Vinci and Michaelangelo, made very careful studies of anatomy in order to render their masterpieces more accurate, whereas Raphael's representation, in the famous picture of the Transfiguration, of a child in a fit with the museles of a developed athlete, is an example of an error which might have been avoided. Dr. Cabanès then refers to Pasteur and Chareot as artistic spirits, quoting Paul Richer's dictum that a work of art is the translation of an idea into material language.

The morbid conditions reproduced in pictures and sculpture are considered in successive chapters, the first dealing with facial affections, such as rhinophyma, asymmetry, paralysis, spasm, and one of leishmaniasis on an ancient Peruvian vase of the period of the Incas. Various dwarfs, pygmies, and court jesters are copiously reproduced, and the chapter on the great historical epidemics is rich in illustrations of bubonic plague and its great patron saint, St. Roch, drawn from the author's private collection. Leprosy also is well represented, and the picture of St. Antony tormented by the Devil, after Matthias Grunewald (1515), is reproduced, with a note about the nature of the lesions shown—syphilis, leprosy, plague, or, as the author follows J. K. Huysmans in believing, gangrenous ergotism. In the chapter on hysteria and hysteroc epilepsy, which Chareot and Paul Richer and Meige so thoroughly explored, the author points out that demonic possession was hysteria, and gives an account, with illustrations, of the well-known dancing mania of St. Guy. The phenomena of insanity and epilepsy are graphically depicted; then representations of surgery from the time of the siege of Troy are dealt with; and in the section on pathology in art urologists and dentists find a place. In an appendix on the thyroid gland Professor van Leersum's recent article in *Janus* on this subject is laid under acknowledged contribution.

This pleasantly written monograph provides a most useful store of information, which those interested in the history of disease will do well to consult.

## NOTES ON BOOKS.

As a change from the encyclopaedic catalogues of symptoms which the American medical author seems to delight in inflicting upon the reviewer, it is refreshing to meet with Dr. FRANCIS W. PALFREY's book on *The Specialties in General Practice*.<sup>7</sup> Dr. Palfrey has compiled his book in collaboration with professors and instructors at the medical school of Harvard University. Its production is justified in the preface by the obvious truism that "the total of medical knowledge has become so large that it is beyond the capacity of any one man to have a complete command of the whole in all its branches." A less trite argument is that "books on special subjects are, for the most part, written from the point of view of the specialist," often laying emphasis on rare conditions and operative procedures which are of subsidiary interest to the general practitioner. Dr. Palfrey has kept his contributors well in hand; they have summarized sanely the knowledge which the general practitioner should possess in the specialties, and have rightly avoided controversial discussion. Thus few people could object to the preface on the delicate subject of sexual hygiene with which Dr. Dellinger Barney opens his section on genito-urinary surgery. Dr. H. C. Solomon will have on his side many experienced general practitioners when he says that the prevailing idea that small doses of alcohol are helpful in the cure of alcoholism is probably incorrect. Dr. J. R. Toubert's proposition that extension of the mother's thighs diminishes the risk of rupture of the perineum may be

<sup>6</sup> *Esculape chez les Artistes*. Par Dr. Cabanès. Paris: Le François. 1928. (5½ x 7½, pp. 403; 198 figures. 15 fr.)

<sup>7</sup> *The Specialties in General Practice*. Compiled by Francis W. Palfrey, M.D., in collaboration with various authors. Philadelphia and London: W. B. Saunders Company. 1927. (6 x 9½, pp. 748. 30s. net.)

correct, but seems inconsistent with the presumably natural squatting position in parturition. The book is a readable summary of useful knowledge.

*Fighters of Fate: A Story of Men and Women who Have Achieved Greatly Despite the Handicap of the Great White Plague* is the title of a book by Dr. J. A. MYERS, Associate Professor of Preventive Medicine in the University of Minnesota, who sketches the life stories of twenty-four persons prominent in very different walks of life in order to encourage the victims of tuberculosis by showing how much can be done by others similarly stricken. The female representative is Elizabeth Barrett Browning, and among the twenty-three men Schiller, Bichat, Laennec, Keats, E. L. Trudeau, Lawrason Brown, and McDougald McLean represent the medical profession. Nicolo Paganini and Frederic Chopin stand for music, Aubrey Beardsley for pictorial art, Cecil Rhodes for statesmanship, St. Francis of Assisi for the Church, and Dostoevsky, Leigh Hunt, Artemus Ward, and others for literature. Rather curiously R. L. Stevenson is only mentioned incidentally as a patient of Dr. E. L. Trudeau, but Dr. Myers has wisely disarmed any criticism by frankly admitting his difficulty in choosing those to include. Some of the people he describes are fortunately alive, such as Dr. Lawrason Brown, Mr. Albert Edward Wiggam, who, it is delightful to hear, "plays nine holes of golf every day" and "lectures even before such medical groups as the clinical staff of the Mayo Clinic," and Will Irwin, an American author, a list of whose works is thoughtfully appended. Tuberculosis has been credited with causing mental exaltation—for example, Chopin is said to have been thus enabled to compose some of his masterpieces—but Dr. Myers considers a more trustworthy explanation is that the enforced physical inactivity provides more opportunity for mental work and output.

## Nova et Vetera.

### VILLEMIN—PIONEER.

#### A CHAPTER IN THE HISTORY OF TUBERCULOSIS.

The hundredth anniversary of the birth of Villemin was celebrated recently in Paris. He it was who convinced a large proportion, if not the majority, of the leaders of French medical thought that tuberculosis was a specific communicable disease, and through them many of the physicians and pathologists of other countries, though it needed the demonstration by Koch of the tubercle bacillus to clinch the matter and convince everybody. It may seem strange to-day that the fact should ever have been in doubt, and it is not easy fully to realize the state of confusion that existed about pulmonary consumption in the middle of the last century. The prevailing belief among the public was that it was inherited, and the current opinion in the medical profession was that it was due to a diathesis. In the Mediterranean countries there were traces of a popular belief, shared by some members of the medical profession, that it was contagious. This was sufficiently well known in France to cause experiments to be made, but these yielded negative or ambiguous results. In 1843 Klencke claimed to have produced generalized tuberculosis by injections into the jugular of certain cells he identified as tuberculous, but he failed to impress German medical opinion.

Villemin's early work was received in a critical spirit by his own countrymen. It was deemed revolutionary, as, indeed, events proved that it was. He was helped to form his views about tubercle by the study of disease in animals. He found analogies between tuberculosis and glanders, which Gohier in 1813 had proved to be contagious and inoculable from horse to horse, and Roger in 1842 to be transmissible from horse to man. Villemin had observed how glanders spread in the regimental stables, and he made use of the analogy when he wrote, "We cannot escape from the idea that in the production of phthisis the barrack is for the soldier what the regimental stable is for the horse in the production of glanders." Again, he observed that the poor man's cow feeding by the roadside escaped tuberculosis, whereas in some big dairy

farms nearly every cow succumbed. He studied his subject with great energy for years, and found many more facts of human and animal pathology all converging to the same conclusion, but he encountered also many difficulties, including the circumstance, emphasized by Laennec, that phthisis did not habitually spread in poor families living under the worst conditions, and the opinion of Virchow, whose influence was then dominant, that "caseous pneumonia" was not tuberculous.

Villemin was in no hurry to publish, but his first essay, which appeared in 1861, showed the direction in which his mind was working. It was not until December 5th, 1865, that he brought before the Académie de Médecine in Paris his conclusion that tuberculosis was a virulent specific disease. The thesis rather took the academicians' breath away, but after considering the matter for nearly a year it was seen that its consequences were too big to warrant any decision, except after experiment and ample discussion. Accordingly in October, 1866, a committee of some of the most distinguished French pathologists of the day was appointed. Its report, presented by Colin a year later, showed that its members were sitting on the fence; they confirmed the accuracy of Villemin's work, but were not prepared to reject the theory that tuberculosis might occur spontaneously. There ensued a debate which, as is the way of the Academy when it is interested, dragged on until the long vacation of the ensuing year. Colin's report was then accepted and the essential part of Villemin's contentions thus approved. Meanwhile he had assembled his observations and arguments in a book which was widely read, and he had won some powerful supporters; among the pathologists perhaps the most influential was Cornil.

Laennec had maintained what was called the "unity of phthisis," a view, as has been said, afterwards attacked by Virchow. But Laennec and the majority of the clinicians who followed him were impressed by the fact that there was little evidence of the transmission of phthisis from one adult to another. Professor Bezaucou, who delivered the principal speech at the celebration, called attention to the fact that when Villemin first promulgated his theory infantile tuberculosis was little understood. It was now realized, Bezaucou said, that it was necessary to consider separately the problem in the child and in the adult. The fact that the infant's organism was very sensitive to tuberculous infection dominated the whole pathological story. In the adult, with his more resistant organism, though infection might occur and was always to be feared, "the danger is rather in the re-awakening of a tuberculosis of infancy which had become latent"; consequently the problem was the study of the reasons why the latent tuberculosis was re-awakened rather than to discover the causes of contagion. Had Villemin been aware of this he would have had less difficulty in convincing the clinicians of his day.

There was a considerable body of opinion against him in France, Germany, and England, among pathologists as well as clinicians. It is indeed strange that so many should have blundered in their experiments and in the interpretation of them. It was, perhaps, because bacteriology was in its infancy; the fact that microbes bred true was not fully assimilated, nor the need for precautions to prevent contamination thoroughly grasped. As this new department of science developed not a few of its votaries began to make tentative experiments with tuberculous products, until Koch, the most famous of Villemin's followers, by the happy thought of the solid culture medium, and by working out a new technique, discovered the tubercle bacillus in 1881 and convinced all.

Villemin was the son of a small farmer in the Vosges, and hoped to become the village schoolmaster, but he was conscripted. His colonel sent him to study medicine at Strasbourg, and he entered the military service of the French army; quite early in life he became professor in the army medical school at Val de Grâce. He was elected a member of the Académie de Médecine in 1874; eighteen years later he became its vice-president. Professor Achard, the present general secretary of the Académie, said, during the celebration, that he would certainly have become its president but for his early death, which occurred in 1892.

## THE DECLINE OF TUBERCULOSIS.

SIR ROBERT PHILIP, in his recent address at Bath to the Society of Medical Officers of Health, printed in our opening pages this week, has turned his attention to the causes of the decrease in tuberculosis mortality. That a great decline in the mortality from the disease has occurred and is occurring in this country is matter of common knowledge. It may be readily confirmed by a comparison of the tuberculosis death rate in the middle period of last century with the happier conditions of the present day. The rate of decline has followed, on the whole, a fairly uniform course, except in so far as it may be held to have been accelerated during recent years. Tuberculosis is a disease which is prevalent in animals, from which it may be passed to man; it is capable also of being transmitted directly from man to man under certain conditions. In the human subject it usually runs a somewhat protracted course. . . . in its early non-infective stages, . . . to diagnose, to the infective lesions of its terminal phases, which are too gross to escape observation. Under such conditions it is scarcely to be expected that the variation of any single factor could have produced the progressive fall. The question of the causes which have been at work is one of considerable complexity. Tuberculosis, however, has been to Sir Robert Philip the interest of a lifetime, and he is therefore well fitted to speak with authority on the causes of its decline.

The antituberculosis campaign which developed in this country soon after 1911, aided by the funds made available by sanatorium benefit under the national insurance scheme, and by the moneys then voted by Parliament for the construction of institutions for the treatment of tuberculosis, was inspired in great measure by the linked dispensary and sanatorium system which Sir Robert Philip had established in the city of Edinburgh. He properly ascribes to this class of work a share in the credit for the reduction in the incidence of the disease, though he does not lay such exclusive stress upon it as some who have elsewhere carried on schemes modelled upon his example. Recognizing that the downward course of the tuberculosis death rate had begun long before any formal antituberculosis regime had been instituted, he seeks his solution in those causes which began to operate as a result of the movement which followed the Royal Commission of 1869. An awakened interest in sanitary matters, an improvement in the educational standards of the people, a diffusion of general and special knowledge among classes previously excluded, a betterment of housing and working conditions, higher wages, shorter hours, better feeding, the open-air life—all these contributory factors have, in his view, increased communal vitality and tended to curb the ravages of the disease.

It is probable, too, that many of these contributory factors have acted also in a direct manner by cutting across the path of infection and reducing the frequency of the opportunities for the transmission of the virus to children at young ages. The path of infection between bovine animals and man is being closed, as a result of recent milk legislation, by the sale of milk from tuberculin-tested herds, and by the Tuberculosis Order of 1925. But these specific factors, valuable

as they are, were preceded, and are still being reinforced, by that group of causes which, taken together, make up what is known as the social uplift: an influence which has, with some few exceptions, been ranged on the side of health—unconsciously hygienic during the ages when medicine itself was ignorant, consciously hygienic at the present day, when medicine, owing to its notable advances, is able to contribute in such an effective manner to the welfare of the community.

It is true that medicine in the case of tuberculosis has not yet evolved a generally accepted specific prophylactic. It is possibly true that some part of the treatment of tuberculosis as now carried out is uneconomic, when cases come under notice too late to be cured, so that expense is incurred in the protracted treatment of those who can never regain their working capacity. Even if it were so, the linked antituberculosis system is well justified of its works, for the treatment of the obviously sick is not the sole or the principal object which it serves. The tuberculous infection is followed back into the homes of the people; early associated cases are discovered and put on treatment; the pre-tuberculous are shepherded along the paths which lead to health; defective environmental conditions are rectified; and an unobtrusive, but potent, antituberculosis propaganda is set on foot, precisely in the places and among the people by whom it is most required.

Sir Robert Philip, in a personal reference with which his address begins, touches on the work of Villemin. A note on this pioneer in the study of tuberculosis which appears elsewhere in this issue (p. 720) will be read with mingled interest and regret by many who had frequent occasion, during his lifetime and tenure of office, to delight in the cogent and graceful pen of Sir Dawson Williams. In this note, written a few weeks before his death, our late Editor refers to the critical spirit in which Villemin's early work was received, and tells how the French Academy of Medicine sat firmly on the fence when presented by Villemin with an essay in which he showed tuberculosis to be a virulent specific disease. The lives of medical pioneers have too often fallen in unpleasant places. Harvey, when he discovered the circulation of the blood, lost much of his practice. Jenner's *Enquiry* was rejected by the Royal Society. Lister encountered hostility and opposition for many years. Sir Robert Philip, living in a more enlightened age, has had better fortune. His election to the Presidency of the British Medical Association, the position which he now adorns, is not only a mark of the personal esteem in which he is held by the profession, but also a recognition of the distinguished part he has played in the movement for the control of tuberculosis, of which, as he says with characteristic moderation in the closing paragraph of his address, the outcome appears satisfactory.

## THE ANAEMIA OF MALIGNANT DISEASE.

THAT anaemia is often associated with malignant disease, especially with cancer in its later stages, is a common observation. This anaemia may be of any degree of severity, and in the severer degrees may form a picture almost indistinguishable from that of pernicious anaemia, and in some cases may form so prominent a symptom as to dominate the clinical picture. This condition has been discussed and carefully analysed by Dr. David Eisen.<sup>1</sup> He finds that in

<sup>1</sup> Anaemia as a Predominating Symptom in Malignant Disease. David Eisen, M.B.Tor. *The Canadian Medical Association Journal*, vol. xvii, No. 12, p. 1506.

cases in which the anaemia constitutes a predominant symptom in malignant disease the patients' complaints may largely be referable to the anaemia, and that measures tending to its relief may sometimes result in considerable temporary improvement. He divides this class of patients into three groups, according to the relative predominance of the anaemia over the other associated symptoms. In the first group are comprised patients who present a marked anaemia of the primary type, accompanied occasionally by other symptoms of primary pernicious anaemia, but with no definite evidence of malignant disease. In this group the malignant disease present is usually cancer of the stomach, and many writers have commented on the occasional resemblance of the blood picture in this condition to that of pernicious anaemia. In the second group are included patients who present a clinical syndrome sufficiently characteristic of malignant disease to cause its presence to be suspected, but not definitely established, and in whom the associated anaemia overshadows the remaining symptoms. The third group is composed of patients who present definite evidence of malignant disease—usually of the gastro-intestinal tract—and in whom the symptoms are largely due to the accompanying anaemia.

As a typical example of the first group Dr. Eisen records the history of a man, aged 59, who was considered to be a case of pernicious anaemia even during treatment in hospital. It was only on his second admission to hospital that evidence of gastric retention was obtained, and x-ray examination then showed advanced carcinoma of the mid portion of the stomach, the patient dying two weeks later after a palliative operation. Necropsy revealed the stomach to be infiltrated by a firm colloid-like tumour undergoing ulceration, which microscopic examination showed to be an adenocarcinoma infiltrating the entire stomach wall and extending into the serosa. Dr. Eisen contends that the diagnosis of pernicious anaemia made on the first admission would seem justifiable in the presence of achylia, dorsal sclerosis, and marked anaemia of a primary type in a well-nourished man with a virtually negative roentgenogram and absence of evidences of external haemorrhage. Moreover, this diagnosis was strengthened by the apparent improvement after hospitalization.

That malignant disease, especially of the stomach, simulates pernicious anaemia has long been recognized. Minot and other writers, though admitting the association of a pronounced haemolytic anaemia of the primary type with malignant disease, will not admit that it constitutes the causative factor of this anaemia, especially in cases in which the severity of the anaemia appears to be out of proportion to the extent of the lesion. Minot, however, suggests that the pernicious anaemia may in some way predispose to the development of the malignant disease. Several writers—Sounenfeld, Naegeli, Hirschfeld, and Zadek—record cases in which cancer of the stomach has developed during the course of pernicious anaemia. Although it cannot be denied that the simultaneous presence of malignant disease and pernicious anaemia may be a mere coincidence, Dr. Eisen will not accept this as an explanation of all cases of malignant disease with a pernicious anaemia syndrome. It would be difficult on this basis, he contends, to explain why the great majority of the cases of malignant disease which offer difficulty in differential diagnosis from pernicious anaemia are cases of cancer of the stomach, in which the anaemia is usually severe. Much more

definite clinico-pathological evidence is needed to support the view that pernicious anaemia offers a specific predilection for the occurrence of malignant changes in the stomach. Further, it cannot with certainty be proved in any case that cancer of the stomach became superimposed upon pernicious anaemia, as gastric carcinoma may notoriously be present for a long time without presenting any characteristic symptoms. A typical case of the second group is also recorded in which the anaemia was the outstanding feature and appears to have been the actual cause of death. The comparatively high colour index, the extreme anaemia with leucopenia and relative lymphocytosis, in the absence of evidence of external haemorrhage suggested the diagnosis of pernicious anaemia early in the disease, and the *post-mortem* findings of increased pigment deposits in the viscera support this view. Haemolytic anaemia associated with malignant disease appears to be uncommon. The close resemblance to pernicious anaemia of the two cases cited suggests an etiological relationship for the anaemia. Whether, however, the achlorhydria played an etiological or an adjuvant role in the production of the anaemia, or whether all the phenomena were caused by a circulating toxin, is difficult to state. An illustration of the third type of patient is provided by the case of a housewife, aged 62, in whom the palliative effects of transfusion were demonstrated. This probably results from stimulation of the haematopoietic system, and may be expected to occur in cases of malignant disease with symptoms mainly referable to the anaemia. The possibility of haemolysis after transfusion cannot be ignored, as mentioned by Ewing, who considers that it is due to a toxic action on the transfused blood by haemolysins engendered by the absorption of necrosing tumour tissue, to which the patient's own blood appears resistant. It is not at all clear why such pronounced anaemia should occur in certain patients with malignant disease; probably several factors are at work, including persistent haemorrhage, impaired nutrition, absorption of necrosing tissue, and occasionally haemolysis. Aplasia of the bone marrow, except as secondary to chronic haemorrhage, does not appear to present any definite relationship to the malignant process.

To whichever of these three clinical groups the patient belongs he may expect to obtain considerable alleviation of his symptoms from the adoption of measures directed to the relief of the anaemia, chief amongst which stands blood transfusion. The danger of haemolysis of the donor's blood, however, should be kept in mind, and tests for this possibility should always be made beforehand.

#### GENERAL PRACTITIONERS AND THE DAWSON WILLIAMS MEMORIAL FUND.

IN our issue of March 17th (p. 461) we published the first list of supporters of a memorial to Sir Dawson Williams. The project began in January as a Testimonial Fund in recognition of the great services rendered to medical science and the medical profession by Sir Dawson Williams during the thirty years he served as Editor of the *British Medical Journal*. His sudden death on February 27th, less than six weeks after retirement from the editorship, prevented his many friends and admirers throughout the profession from making this public acknowledgement of their esteem and regard during his lifetime, but the Executive Committee decided, very rightly, that what had been done should be continued with the object of establishing a worthy memorial to a great benefactor of British medicine. Its

form will be decided upon, in due course, when the subscribers have been consulted. In the meanwhile we are asked to make it known that the Fund is still open, and that further contributions, small or large, will be welcomed, in order that the memorial may be widely representative of every branch of professional work and study, and not least of the great body of general practitioners, whose interests Sir Dawson Williams had ever at heart from beginning to end of his editorship. The fullest participation in this project by those whom he so often spoke of as "the working doctors of the country" would be more than fitting; indeed, without it this memorial, whatever the sum raised, would be inadequate. Many general practitioners have already subscribed generously, but the response will, we hope, soon be even more widespread. The names of all contributors will be acknowledged in these columns. Cheques should be made payable to Sir St. Clair Thomson, who is acting as Treasurer of the Fund, and sent to 64, Wimpole Street, London, W.1, and the envelopes marked "Dawson Williams Memorial."

#### NEW LIGHT ON YELLOW FEVER.

THE study of yellow fever has been greatly advanced by two recent discoveries, which throw a new light on the nature of the virus and incidentally furnish additional evidence that *Leptospira icteroides* Noguera is not the causative organism of this disease. Since 1925 the West African Yellow Fever Commission of the Rockefeller Foundation, with headquarters at Lagos, has been studying numerous sporadic cases of yellow fever in Nigeria and the Gold Coast, and a recent report<sup>1</sup> by the late Professor Adrian Stokes (who died from the disease), in conjunction with Drs. Bauer and Hudson, contains the first definite record of the transmission of this infection to laboratory animals. The common rhesus monkey, *Macacus rhesus*, and also, to a lesser degree, the Indian crowned monkey, *M. sinicus*, are found to be very susceptible to the disease, which may be transmitted either by the bites of infected mosquitos or by the inoculation of blood from a yellow fever patient. Curiously enough, the local monkeys, and even chimpanzees, were found to be immune, as well as all the ordinary laboratory animals. The disease has been carried thirty times from monkey to monkey by the inoculation of infected blood or serum, with fatal results in every case except one, when the animal recovered and was subsequently immune. In addition, twenty-two monkeys were infected by transmitting the disease from one animal to another by the bites of infected mosquitos (*Stegomyia fasciata*). Mosquitos invariably became infective when fed on infected monkeys during the first or second day of fever, and after an incubation period of not more than sixteen days remained infective as long as they lived. One mosquito produced fatal infections in two monkeys when it was fed to them eighty-five and ninety-one days respectively after feeding on an infected animal. Fortunately, the infection does not seem to be transmitted to the offspring, as large numbers of mosquitos reared from eggs laid by infected females were fed on a monkey with negative results. The course of the disease in monkeys is similar to that in human beings, and the pathological changes, including the *post-mortem* appearances and morbid histology, closely agree with those described as typical of yellow fever. In an attempt to isolate the causative organism cultures were made of infected blood in various media, including those used for leptospirae, and also the tissues of infected animals were carefully examined, but in no case was any organism found that could be regarded as the etiological factor. Moreover, guinea-pigs, which are extremely susceptible to infection with *Leptospira icteroides*,

were quite unaffected by the inoculation of material from yellow fever cases. Independent investigators have shown that *L. icteroides* is serologically identical with *L. icterohaemorrhagiae*, and it is now almost certain that the organism described by Noguera as the cause of yellow fever must have been obtained from cases of Weil's disease, or possibly from patients with a double infection. In our present issue (p. 713) we publish an article by A. W. Sellards and E. Hindle advancing knowledge of the disease a stage further. Working with a strain of yellow fever isolated in Senegal, they were able to confirm the fact that rhesus monkeys are very susceptible to the disease. They then made experiments on the nature of the virus, and found that, like vaccinia, rabies, distemper, and many other diseases caused by filterable viruses, the infective agent is unaffected by cold, and if frozen will maintain its virulence for at least twelve days. It appears probable, therefore, that yellow fever belongs to the group of diseases caused by filterable viruses, and experiments have shown that the virus in the blood can pass through Berkefeld filters V and N, but not through a Berkefeld W. The preservation of the frozen virus affords a simple method of transporting the infection, and as a susceptible animal is now available the disease can in future be studied in regions where the natural transmitting agent, *Stegomyia fasciata*, is absent, and there is no danger of the infection being spread by stray mosquitos. Although it is a little early to assume that the New World is now free from yellow fever, no cases have been recorded since the eradication of the endemic centres in Brazil by means of anti-mosquito campaigns. In West Africa, on the other hand, epidemics of increasing severity have occurred in recent years, and this region still remains a potential source of danger to all tropical countries in which the transmitting mosquito is present.

#### FRACTURED CLAVICLE.

A BROKEN collarbone is such a common injury on the road, in the hunting field, or the recreation ground, and its routine treatment has led to such satisfactory functional results, that there may seem little scope for improvement. Nevertheless it cannot be denied that, except by operation and the introduction of foreign bodies, exact anatomical restoration is very rarely attained. It is generally admitted that such operations should be reserved for very exceptional cases, and we are often left to content ourselves with a result which involves some displacement of fragments and consequent deformity, however slight it may be. Last week (p. 664) we published an article by Mr. Milroy in which he describes a modification of the method of treatment by bandaging which he has found more satisfactory than the ordinary routine proceeding. The use of adhesive strapping instead of bandaging has been advocated by some surgeons of late years, but we do not remember to have seen a report of the effects of its use in a large series of cases, until the appearance of a paper in the *Journal of the American Medical Association* by Dr. Earle Conwell of Alabama.<sup>1</sup> His ninety-two cases, which were all treated during four and a half years in the Employees' Hospital in Fairfield, Alabama, seem to have included more severe injuries than usual, for nineteen of them were complicated by injury to the shoulder-joint and four by injury to the sterno-clavicular joint, which, with nine cases of marked overlapping or displacement, seem all to have been treated by traction and abduction and external rotation while recumbent. Dr. Conwell does not say how many cases were treated with adhesive strapping from the beginning, nor does he give any records of comparative measurements of the injured and sound clavicles

<sup>1</sup> Stokes, Bauer, and Hudson: Experimental Transmission of Yellow Fever to Laboratory Animals. *Amer. Journ. of Trop. Med.*, vol. 8, No. 2, March, 1928.

<sup>1</sup> Fractures of the Clavicle: A simple fixation dressing, with a summary of the treatment and results attained in ninety-two cases. By H. Earle Conwell, M.D. *Journ. Amer. Med. Assoc.*, March 17th, 1928, p. 838.

by which some estimate of the success of the treatment might be formed. With such a wealth of material as the Tennessee Coal, Iron, and Railroad Company appears to provide, it may be hoped that at a future time Dr. Conwell will provide us with exact and valuable data as to these injuries and their anatomical results. The method recommended requires the provision of four strips of adhesive material each four feet long and four inches wide, one large axillary pad, and one small pad of felt to protect the site of fracture. One of these strips is designed to pull back the shoulder, one to pull down the ends of the fragments, another to lift up the elbow and shoulder, and the last to pull the elbow into the side, and thus lever the outer fragment outwards. It will thus be seen that the principles on which the dressing is applied are familiar. Dr. Conwell no doubt rightly concludes that no hearable ambulatory treatment can be trusted to correct cases of severe overlapping of fragments. The method which he has described is worth a trial.

#### EUROPEAN VITAL STATISTICS.

THE importance of vital statistics as the basis for any intelligent system of public health administration is now well recognized, and it is therefore somewhat surprising to learn, from a paper on vital registration in Europe which Major P. Grauville Edge read before the Royal Statistical Society on April 17th, that not only are there countries in which the collection and classification of information of this nature is still on a restricted scale, but also that in some countries, while there are admirable "paper" systems, these systems are not effectively administered. Moreover, in his investigations Major Edge has found wide divergences in practice between one country and another in such matters, for example, as the registration of stillbirths, the methods of death certification, and, most important of all, in the classification of causes of death. It is obviously most unsatisfactory for purposes of comparison that in Belgium, France, Czechoslovakia, Hungary, Germany, and in the rural areas of Scandinavian countries, the declaration of the cause of death may be made by non-medical persons. Variations in nomenclature are very considerable; the detailed international list, which has been in existence for nearly thirty years, is used only in England and Wales, Scotland, Ireland, Czechoslovakia, Holland, Germany, and the United States. In two of those countries, however, as already mentioned, definition by non-medical persons of causes of death vitiates the value of the final figures. Four European countries use the abridged list only, and a number use special nomenclatures. No uniformity exists in methods of collecting data. The practice in certain countries of having statistical summaries completed by local authorities as the basis for the national returns means, in Major Edge's words, that "technical operations requiring specialized knowledge may be carried out by people lacking either medical qualifications or the statistical training necessary to the task." Many further examples could be quoted from this source to show that extreme caution must be exercised in any attempt to compare the vital statistics of any two or more European countries; the completely conscientious statistician who desires to employ such comparisons will be forced, indeed, to begin by comparing the relative national systems, and that is no light task. Apart from the difficulty arising from differences, however, the known deficiencies in some cases rob the national figures of much of their potential value. In Great Britain the position appears to be more satisfactory than elsewhere, and Major Edge believes there is more danger of the central statistical authorities attempting to do too much than of their task suffering from neglect or bad organization. He suggested that some of the official statisticians seek to get more from statistical returns than these returns can fairly be expected to yield,

and stated that some of the proposals for improved classification which he had seen seemed to postulate in central offices a greater ability to determine accurately what caused a death than was possessed by a certifying practitioner. Many doctors will no doubt sympathize with the sentiment which Major Edge expressed in his closing remark, that "there is even a danger that, if the central authorities take too much upon themselves, medical practitioners may pay even less attention than they do at present to the official publications."

#### THE "PRODUCERS' BUDGET."

WHEN Mr. Churchill took control of the nation's finances his reputation for vision, administrative capacity, and political courage created a general expectation that his Chancellorship would prove memorable for its permanent effect on our financial policies. In his progress towards achievement on the grand scale Mr. Churchill has been impeded by the clogging weight of debt redemptions and readjustments, by the reduction in receipts which inevitably follows a reduction in the general price level, and lastly, by the upheaval and trade dislocation which followed the general strike, the prolonged effects of which raised an exasperating obstacle in the path to those large financial reforms which Mr. Churchill has now outlined. It is obvious that the Government's proposals will be subjected to criticism from many quarters, but they are evidently the result of long and careful study, and in the main appear to be wisely directed to the urgent necessity for removing the heavy pressure of local rates on the basic industries. In his Budget speech Mr. Churchill devoted more time to an explanation of the proposals for debt redemption than is usually given to that topic. The minor features of the fiscal changes will excite little opposition or enthusiasm. The additional taxes—6d. each on mechanical lighters, 33½ per cent. *ad valorem* on imported buttons "not already attached," and an additional 6d. per gallon on British wine—are not likely to arouse much indignation, nor is the hoped-for drop of one farthing in the retail price of sugar as a result of a slight reduction in the sugar tax likely to be very warmly acclaimed by British housewives. The increase in the children's allowance for income tax is welcome; to those taxpayers whose income is assessed to any considerable extent at the standard rate the additional relief afforded will be £9 8s. in respect of two or £18 12s. in the case of four children. Incidentally, one result of the change will be to raise appreciably the effective limit of assessment to tax in the case of parents as distinct from other taxpayers—a development which Mr. Churchill humorously referred to as "another application of our general policy of helping the producer." The chief interest, however, in the proposals centres round what is obviously the preliminary announcement of a bold policy for the removal of one of the serious handicaps under which the older British industries are labouring to-day—the pressure of local rates on unremunerative businesses. Mr. Churchill stated the facts concisely and graphically, and made it clear that a vicious circle has been created in many industrial localities, unemployment causing higher rates, which in their turn lead to the shutting down of additional works, more unemployment, and still higher local expenditure. The details, so far as they were disclosed, it is not possible to discuss at this stage. It is evident that Mr. Churchill anticipated, and was prepared to deal with, criticism that performance was to follow next year, and not at an earlier date. We confess that his defence for such a postponement appears sound. The problem can be stated briefly, but any satisfactory solution must take into account so many factors of a very complex situation that the fullest possible preparation and discussion of the detailed proposals are essential if success is to be achieved. The principle of forming a fund to start the new scheme before it can be put

into operation is unusual, to say the least, in dealing with this type of problem, though its application to insurance schemes will be familiar. On this point the Chancellor has shown his courage; for the sake of the soundness of the scheme he is willing to give a temporary advantage to his critics. As with so many otherwise beneficial schemes, this proposal has its disadvantage in the necessity for providing large sums which can only be raised by taxation, and Mr. Churchill has fallen back on the consumers of petrol to supply him with ammunition for his fight on behalf of our basic industries. Presumably he has been led into this step by the low level of recent prices as compared with those of a year or two ago, and, in the case of heavy lorry consumption, by the apprehension that the growing competition with the railways is leading to an uneconomic competition for heavy traffic. We are disposed to think that a *prima facie* case has been made out for the proposals in principle, but a considered view of the arguments against it has not yet been developed, and undoubtedly on points of detail further information and discussion are essential. For instance, the proposed exemptions from the duty are restricted to oil used afloat in the fishing fleets, bunker oil, and light oil used in agricultural tractors. Doubtless there will be many other claims for similar privileges, and we trust that among them the case of the medical practitioner will not be overlooked. He is a "producer" of essential services to the community—vital services literally as well as figuratively—and as such can fairly claim that he should not be seriously penalized by a producers' Budget. We are inclined to doubt whether the Chancellor has sufficiently taken into account the very great extent to which light cars are used for professional and business purposes in circumstances in which an increase in running costs by taxation would impose an unfair burden on the taxpayer.

#### INCOME-TAX RETURNS FOR 1928-29.

Most of our readers will already have received from the local inspector of taxes the form for the declaration of income on the basis of which income tax will be paid for 1928-29. The issue appears in general to have been made at an earlier date than usual, and in most cases the declaration required will probably appear more formidable than ever. We understand that the fundamental reason for these changes is the desire to avoid the troublesome multiplication of requests for declarations which in the past have been a source of very natural annoyance to those taxpayers who, as in the case of some medical men, hold an appointment or an office the income from which falls within the jurisdiction of different authorities. Whether this desire is alone responsible for the promptitude with which the forms were sent out at the opening of the new financial year we do not know, but presumably, if it should lead to speeding up of the official labours, earlier application for the amount due, and earlier payment of the tax, the Treasury would derive additional satisfaction from the new departure. It is, of course, clear that if a single statement is to be accepted it must be made in sufficient detail to enable the separate items of taxable income to be correctly assessed. We have not apparently yet reached the stage at which the authorities are prepared to assess the whole liability of a taxpayer from one office; that would clearly be the most convenient arrangement from the taxpayer's point of view, and perhaps the unification of his declaration is a step in that direction. Where there is income liable to direct assessment it may be regarded as falling either under Schedule D or under Schedule E—the latter dealing with the earnings of employment. Hitherto the authorities have supplied one form of declaration for each schedule; this year two alternative forms are in use in each case. It would seem that where the income of the particular taxpayer is thought to be

fairly simple to declare, then the declaration required—No. 11A or 12A—is restricted to a single statement of total income, together, of course, with the completion of any claims to relief in respect of children, life assurance, etc. Where, however, the income is complicated, and particularly where liability to super-tax may exist, the form of declaration—No. 11 or No. 12—has been expanded to provide, *inter alia*, for the separation of the assessable portion of the income from that which is taxed by deduction or dealt with under Schedules A and B. If this fundamental distinction be borne in mind the form will be less puzzling than it may appear to be at first sight. The severance of the assessable income from the remainder has no doubt been effected partly because of the position with regard to super-tax. For 1928-29 separate super-tax returns will apparently be required, but from 1929-30 onwards the intention is that the income-tax declarations shall serve the purpose of the super-tax, or rather of the "surtax," to give it the name it will then bear, as well as of the ordinary income tax. Unfortunately for the achievement of complete simplicity, assessable income is measured for income-tax purposes by the amount of the income of the previous year, whereas income taxed by deduction is regarded as income of the year of receipt. Bearing this in mind, and also the fact that super-tax is chargeable on the amount of income liable to income tax for the previous financial year, it will be realized that the maintenance of a line of division between the two classes of income for each year will assist the taxpayer in seeing how the amount liable for super-tax has been calculated from his declarations—for example, that amount for the year 1929-30 will be the aggregate of the assessed income for 1927-28 plus the other miscellaneous income for 1928-29. In this connexion we may perhaps point out the advisability of retaining a copy of the declaration made; duplicate forms for the purpose can be obtained by application to the inspector of taxes. The authorities have stated very definitely their desire for one complete return only, and any medical man receiving a second form—for example, in respect of some appointment or owing to a change of address—should return it uncompleted except for the insertion of particulars as to the address, etc., from which his full declaration has been made.

#### DEATH OF DR. J. A. MACDONALD.

We have to announce with sorrow the death, at Taunton, after some months of progressive ill health, of Dr. J. A. Macdonald, LL.D., one of the most popular and most respected leaders of the British Medical Association during the past quarter of a century. Dr. Macdonald became Chairman of Representative Meetings in 1906, retiring in 1909, and then held office as Chairman of Council for the unprecedented period of ten years. Since 1920 he had been Chairman of the Journal Committee, and a staunch friend of this *Journal* it would be impossible to imagine. He visited on behalf of the Association the Australian and New Zealand and some of the Far Eastern Branches in 1914, and went on a similar errand to South Africa six years later. He had been a direct representative of the profession on the General Medical Council since 1911, and for a considerable period was a member of its Executive Committee. Notwithstanding the heavy claims upon a general practitioner in single-handed country practice, he thus found time through many eventful years to give unsparingly of his best to his profession. Whenever the British Medical Association needed exceptional services, demanding sound judgement, devotion to the interests of the Association, and a commanding personality, it called on Dr. Macdonald, and never in vain. We hope to publish a memoir, with personal appreciations and a portrait, in our next issue.

## AN OFFICIAL VISIT TO SOUTH AFRICA.

BY

H. B. BRACKENBURY, M.R.C.S., L.R.C.P.,  
CHAIRMAN OF COUNCIL, BRITISH MEDICAL ASSOCIATION.

IN September last the Federal Council of the Medical Association of South Africa (British Medical Association) wrote asking the Council of the British Medical Association to send representatives to the twenty-second South African Medical Congress to be held at Bloemfontein in the week beginning March 12th, 1928. The particular occasion was not merely the twenty-second Congress, but also the first annual scientific and first annual general meeting of the Medical Association of South Africa (British Medical Association), which had been formed a year previously by the amalgamation of existing, and sometimes conflicting, medical organizations, largely through the efforts of Dr. Alfred Cox during his visit to South Africa from November, 1926, to April, 1927. It was felt that official representation of the parent Association on this occasion would help to consolidate the position that had with some difficulty been achieved, and would be an effective demonstration of the bond which now intimately unites the Association in South Africa with the British Medical Association. It would, of course, have been delightful if the Medical Secretary himself could again have been the ambassador, but it was impossible to spare him from the Central Office. It was hoped that the President of the Association (Sir Robert Philip) and Sir Robert Bolam might be able to undertake the service, but, this also being found impossible, the Council of the Association ultimately asked its present Chairman to perform this duty as its representative. It was ascertained that certain other members of the Association of suitable status and experience would be in Africa during March, and, at the request of the Council, Sir Frank Colyer, Dr. H. B. Denham, and Dr. C. D. Hatrick consented to attend the Bloemfontein meeting as official delegates of the Association.

My wife and I left England by the *Edinburgh Castle* on February 10th, arriving at Capetown early on February 27th. Our return journey was by the *Windsor Castle*, which sailed from Capetown on the evening of March 23rd. We were thus barely twenty-six days in South Africa, a time too short to see and do all that was desirable, but long enough, with everyone conspiring to make the period as full as possible, to enable us to gather some vivid impressions, to realize generally the conditions of life and medical practice, to grasp a number of interesting problems, and to experience abundant kindness and hospitality from all with whom we came in contact. We were unfortunately unable to visit Rhodesia, or any of the larger towns in the Cape Provinces, such as Port Elizabeth and East London; but we travelled, I suppose, more than 3,000 miles by train and some 1,000 by car. We spent some five days in Capetown, eight days in Johannesburg, more than five days in Bloemfontein, and four in Durban. From Capetown we visited Simonstown, the naval station, and, indeed, the whole of the Cape peninsula, certainly one of the beauty spots of the world; also Stellenbosch, which has been called the Oxford of South Africa, and which is, at all events, a very pleasant little place, with a large number of fine schools and educational institutions, and the seat of the largest purely Dutch university of the country. From Johannesburg we spent some time in Pretoria, a finely situated town of great beauty, and, of course, the administrative capital of the Union.

From the moment of our arrival at Capetown, where we were met by Drs. Leipoldt, Impey, and Marais, till Drs. Pearson and Drummond saw us off from Durban—even till Dr. Jones-Phillipson, and Dr. Leipoldt again, bade us farewell at Capetown dock—our way was made easy for us by the facts that a full and very enjoyable programme had been arranged, and quite a large number of doctors and others readily sacrificed time, work, and energy on our behalf to a degree which was really embarrassing. This was true in a superlative degree of Dr. Orenstein during our stay at Johannesburg. All this not merely enabled us to visit many interesting places and to experience many

delightful features of life in South Africa, but afforded me time and opportunity to meet individually or collectively medical men and women in all branches of the profession—in the Government medical service, in the railway service, in the service of the mines, naval surgeons, research workers, medical officers of health, members of hospital staffs, specialists in various classes of practice, and general practitioners, both urban and rural, as well as the president and some of the members of the Colonial Medical Council. Such personal converse I found most useful in helping me to appreciate the conditions, difficulties, and advantages of medical practice in South Africa. In addition I was able to address the council of the Cape Western Branch, presided over by Mr. Lindsay Sandes; the council of the Natal Coastal Branch, at the invitation of Dr. J. Drummond; the executive committee of the Johannesburg Division of the South Transvaal Branch, presided over by Dr. Harvey Pirie; two general meetings of the profession—one at Johannesburg and one at Durban—as well as the Annual General Meeting of the Association at Bloemfontein. I was also privileged to attend two meetings of the Federal Council, and to speak at two of the sectional scientific meetings of the Congress on subjects which were largely concerned with private practitioners in relation to questions of public health.

The variety of topics on which one was asked to express an opinion, and the variety of circumstances in which one was asked for individual advice, at these interviews and meetings were considerable. Beyond a few internal Association questions, such as the desirability of forming Divisions in certain areas, and the best method of securing a really representative gathering at the Annual Meetings, the two main broad matters with which there seemed to be most concern medico-politically were the position of hospitals and hospital staffs and the establishment of a national health insurance scheme. These are familiar problems in Great Britain, and, though there are many differences in South Africa which have very seriously to be taken into account, the points for determination are similar to those which have had to be decided by the Association and profession here. The latter of the two subjects was the one on which I was particularly requested to address several of the meetings referred to above, and my personal and intimate experience of matters connected therewith probably enabled me to be of some service. In connexion with these and similar matters it seemed desirable that I should attempt to acquire some further knowledge of the general political situation and movements of opinion, and of the method of administration of hospitals and other public health institutions. While at Johannesburg I was fortunate enough to be shown over the very fine and practically effective Medical Research Institute, of which Sir Spencer Lister is the director; to see the Miners' Phthisis Bureau and the work of Dr. Irvine and his colleagues, which has had such gratifying success; to visit, under the guidance of Dr. R. P. Mackenzie, the large General Hospital, whose newly opened operating theatres and x-ray rooms must surely, at the moment, be at least equal to anything of the kind to be found elsewhere; to be conducted over various compounds for native miners and miners' hospitals by Dr. Orenstein, the superintendent of the health and sanitary department of Rand Mines; and to see something of the Union Department of Public Health at Pretoria, of which Sir Edward Thornton is the medical head. At Capetown I had some talk with several politicians and civil servants of influence, and was asked to attend a special meeting of the Parliamentary Commission dealing with the questions of old age pensions and national insurance. This is a small body of members of Parliament, presided over by Mr. Pinaar, a member of the Government, which is now considering the establishment of a scheme of national health insurance. Its secretary is Mr. Collic, an eminent civil servant, and an acknowledgement is due to him of his courteous and painstaking way of dealing with the profession in South Africa in this matter. He was kind enough to come to Bloemfontein to attend one of the meetings of the Federal Council there and explain the position, and to come to the *Windsor Castle* just before its departure and say a word of farewell to us.

The actual Congress to which I and my three colleagues were the official delegates of the British Medical Association was held at Bloemfontein from March 12th to 17th. The president was Dr. Bidwell, the vice-president Dr. de Kock, and the joint honorary secretaries Drs. Alico Cox, Marion Thomson, and Louisa Tomory. To all of these, as well as to the other four members of the Executive Committee, the thanks of everybody concerned are due, for the Congress was a great success. To this all the members of the local profession and their ladies contributed, and they were greatly helped by the Mayor of Bloemfontein, the Administrator of the Orange Free State, the authorities of the Grey University College, and others. The attendance was good, especially as the nucleus of resident members was so small. The sections were all interesting, and some of the papers exceedingly valuable. The entertainments were all of them wonderfully well organized, and all of them enjoyable. The excursions were not many—mainly to neighbouring farms, for Bloemfontein, though a pleasant town, is not the centre of specially beautiful or picturesque surroundings—but one excursion to Glen Agricultural College, situated on the Modder River just sixteen miles out, was particularly interesting. The trades exhibition was opened by Dr. de Kock, and was in every way successful.

The opening ceremony in the Raadzaal was brilliant, Dr. Orenstein, as president of the Federal Council, was at first in the chair, and his remarks were both appropriate and effective. They were addressed to members of the Association as a timely reminder of their duty. The formal opening was announced by the Honourable Mr. Justico de Villiers in an admirable speech, reminding the whole medical profession of its duties to the public, and Dr. Bidwell's presidential address on practical enginics, though decidedly controversial, was an effective reminder to the public that it, too, had great responsibilities in relation to national health. These speeches are reported fully in the *Journal of the Medical Association of South Africa* (British Medical Association) of March 24th. So also is Dr. Drury's unusual and brilliant paper on inhibition, with which the section of medicine and mental hygiene was opened. It is well worth reading. Other papers and discussions particularly worthy of note were concerned with abdominal emergencies (Professor Saint), the action of solanum pseudocapsicum (Dr. Heiman), hay fever (Dr. H. Pirie), the Schick and Dick tests (Dr. Pratt Johnston), bacterial filtrates (Dr. G. Buchanan), and dental sepsis in relation to general pathology (Sir Frank Colyer). The last-named paper was illustrated by some remarkable photographic slides, and certainly made a great impression on those who heard it. Sir Spencer Lister showed a very interesting film concerned with bilharzia. All the papers, however, were judged well worthy of attention and consideration. At the annual banquet Dr. Orenstein and I had the honour of replying to the toast of "The Associations," proposed by Dr. Dreyer, but the feature of this dinner was an extraordinarily entertaining speech by Mr. Lindsay Sandes in proposing the toast of "The Allied Professions."

Looking back upon all these experiences I have the impression of an amazing country of great attraction and enormous possibilities, of a medical profession with high attainment and reasonable prosperity, of an Association united, active, and influential, led by men of great ability, of sound judgement, public spirited, and zealous. There are, no doubt, a few areas in which both unity and activity will need a delicate fostering. There are some difficulties, both of internal organization and of external relationships with communal services and Governmental proposals, but it is the tackling of such difficulties which keeps an association alive and healthy and growing. Clearly the work of Dr. Alfred Cox and of those who with him helped to found the United Medical Association of South Africa was well done, and under leadership like the present will endure and fructify. Among a number of able leaders I shall, I think, be forgiven for saying that the remarkable but diverse personalities of Dr. Orenstein, the president of the Federal Council, and Dr. Leipoldt, the organizing secretary, are an invaluable asset.

I am told that the action of the Council of the British

Medical Association in sending its Chairman to South Africa and appointing delegates to the Congress in Bloemfontein is greatly appreciated, and that what we have been able to do has been of some service. I should like to be permitted to add that the fact that my wife accompanied me has not, I think, been without its public value, for in missions such as this social reinforcement is an aid to success, and the wives of practitioners in South Africa have, I find, at least as much influence as those at home. I believe that the Association here, as well as my wife and I personally, would like to thank all those who so kindly helped and entertained us as representing the Association, and especially Dr. and Mrs. Bidwell and Dr. and Mrs. Drummond, with whom we had the great pleasure of staying in Bloemfontein and in Durban.

## Scotland.

### Glasgow Corporation Venereal Diseases Bill.

A DRAFT bill to provide for the prevention, notification, and treatment of venereal disease was considered on April 12th by the Glasgow Corporation and adopted; the bill seeks further powers of a compulsory nature in dealing with venereal disease. It proposes to make patients responsible for continuing under treatment by a registered medical practitioner as long as they are deemed to be in an infective condition. One clause requires notification to the medical officer of health of persons who default under treatment, the medical practitioner to be responsible for notifying the case. Powers are asked for the medical officer of health to take action in the case of wilful default by requesting the affected persons to resume treatment, and in the event of failure to comply by prosecuting them or removing them to hospital on the order of a sheriff, magistrate, or justice. The bill has also clauses requiring the parents of children suffering from congenital syphilis and ophthalmia neonatorum to submit themselves for examination and, if need be, treatment. Provision is made for the appointment of a medical referee by the Scottish Board of Health to whom aggrieved persons may be referred. The bill is more drastic than the Edinburgh Corporation Bill recently rejected by Parliament. It was pointed out in the corporation's discussion on the Glasgow bill that the necessity for compulsory treatment was being forced on every local authority, and that there were 100,000 sufferers from this disease in Glasgow, of whom at least 75 per cent. were innocent cases. It was suggested that money might much more profitably be spent upon its cure than, as large amounts are being spent at the present time, on the treatment of tuberculosis. A resolution to proceed with the bill was supported by a large majority of the corporation.

### The Edinburgh Chair of Forensic Medicine.

Professor Sydney Smith delivered his inaugural lecture in the chair of forensic medicine at Edinburgh University on April 20th. Principal Sir J. Alfred Ewing, who presided, referred to the great abilities possessed by the late Professor Harvey Littlejohn, and extended a welcome to Professor Sydney Smith, of whose work in Egypt since 1915 he spoke in high terms. The new professor dealt with the position in this country in regard to expert medical evidence in law courts and the training of experts in forensic medicine, saying that at the present day, in nearly every case of crime against the person, medical evidence might be the ultimate dictum which proved the guilt or innocence of the accused person. The subject was thus not to be approached lightly or without due training. Opinions must stand against cross-examination, and authority, which was once of great importance, was a diminishing quantity, so that no opinion could now carry weight unless it rested on something more substantial than authority. Expert evidence based on demonstrable facts was being utilized to a greater extent in every trial of importance in the country, and judicial authorities now demanded a high standard of professional knowledge from the experts. It was important that the medical expert should be in close contact with the investigating authority. In many parts of

the Continent the medico-legal expert with a well-equipped laboratory formed an essential part of the machine for investigation, and it was of great value to the police that they should be able to obtain scientific co-operation when they required it. In England it had been considered to be more efficient and less expensive to employ specialists in different scientific subjects from outside as they were required. This had much to commend it, but those experienced in these subjects knew well that a large amount of information was lost in certain cases. He believed that the time had arrived when an effort should be made to supply medical men trained in forensic medicine to fill the positions of police surgeons, coroners, etc., and that, to facilitate such training, the whole of the medico-legal work of a district should be concentrated in one central place. These conditions were found in Germany and France, and, in fact, in nearly every country except our own. In Egypt, the country with which the lecturer was most familiar, attached to the office of *procureur-général* there were laboratories and scientific equipment, with a personnel of medical officers—pathologists, chemists, x-ray and photographic experts—all of whom were whole-time Government officials. In this laboratory about 800 examinations of viscera for poisons and about 5,000 samples of narcotic drugs had been investigated last year. If these examinations had been made on an individual basis the cost would have been about £45,000, whereas the total cost of the whole section was less than £10,000 per year for more than 10,000 individual examinations and reports. The saving was thus seen to be relatively enormous. Such institutes might well be inaugurated in this country, with a status similar to that which had been accorded to the practice of hygiene.

#### East Fortune Sanatorium.

In the fifth annual report Dr. Charles Cameron, medical superintendent of the joint sanatorium for the south-eastern counties of Scotland at East Fortune, states that the sanatorium for a period in the past year was, for the first time, fully occupied. The demand for accommodation was, however, met except as regards the needs of children, where a certain amount of difficulty was present. The numbers of patients admitted from the contributing counties during the year were: from Midlothian 54, West Lothian 61, Peebles 9, East Lothian 37, Berwick 27, Roxburgh 15, and Selkirk 15. During the year in all 284 patients had been admitted and 252 discharged. Of those admitted, 126 suffered from tuberculosis of the lungs, and in all these cases the disease had been present for a long time before they came to the sanatorium. A large number of cases suffered from disease of the spine or of the joints; many of these had already been treated at hospitals, and afterwards passed to the local authority for sanatorium treatment. A large number required prolonged treatment, and it is suggested that admission for this type of case should be sought at an earlier stage. Of the male patients treated up to the present time for disease of the lungs and chest glands, 204 were much improved, 251 improved, 41 stationary, 373 worse, and 282 died; while among women patients 227 were much improved, 226 improved, 118 stationary, 489 worse, and 92 died. There had been no deaths in children, and 393 were much improved.

#### Prolongation of Age in Scotland.

An address on the question, "Is the health of the nation improving?" was delivered by Dr. William Robertson, medical officer of health for Edinburgh, to the Edinburgh Rotary Club on April 12th. The lecturer said that in 1861 Edinburgh had 170,000 inhabitants, with an annual death rate of 23.1 per 1,000 of the population, while last year the population was over 424,000, with an annual death rate of 14.5. More people were now living to a ripe old age than formerly. Last year, between the ages of 56 and 65 there were 931 deaths, and among those over 75 years of age there were 1,186 deaths, while between the ages of 15 and 45 only 883 persons died. It was becoming increasingly important that attention should be paid to the child population of the cities, because the birth rate had seriously declined. In 1861 the birth rate was 33.4 per 1,000 of the population, while at present it stood about 18.7.

While, however, infantile mortalities of 130 per 1,000 births were commonly encountered over fifty years ago, the death rate among infants had now been reduced to 83 per 1,000 births. Too many C3 people had been bred in the country in the past, but it was expected that a new generation of persons resistant to disease might in future be seen, so that several years would be added to the life span of every individual. If reliance were placed upon vital statistics, it seemed likely that the expectation of life, when the year 2000 A.D. arrived, might, on an average, amount to 82 years. At the present time it was between 58 and 60 years.

## Ireland.

#### Report of the Free State Commission on Clean Milk.

THE report of the Free State Interdepartmental Committee on Clean Milk, which has now been published, recommends the adoption of the "accredited herd" system in operation in the United States of America, and among other recommendations it is suggested that all milk vendors in county boroughs and urban districts should be licensed annually by the sanitary authority personally and in respect of the premises used by them for trade purposes. In the event of refusal of a licence a right of appeal to the district court might be given. The definition of milk should include buttermilk, skimmed milk, and separated milk; bottling should be undertaken only on registered premises, and the bottles used for milk should be of standard size and be stamped with the measure of their capacity. The sale of objectionable articles in the same shop as milk should be forbidden. The committee considers that a dairy employee should be made liable (in place of his employer) for an offence under the dairy regulations, if it is proved that he has deliberately neglected to use conveniences provided for the protection of the purity of milk. Provision for small loans to individual borrowers for the purpose of improving their cowsheds is recommended. Administrative action to have the Bovine Tuberculosis Order, 1926, extended to include "any cow showing clinical signs of tuberculosis and excreting tubercle bacilli" is urged. The use for human food of milk from cows suffering from specified conditions should, it is suggested, be restricted. Diphtheria in dairy employees should be included in the Public Health (Pneumonia, Malaria, Dysentery, etc.) Regulations, 1919. It is advised that a revision of the Dairies, Cowsheds, and Milkshops Order, 1908, be undertaken, with special regard to inspection of cattle, the grooming of cows, the lighting, floor construction, and drainage of cowsheds, the washing and sterilization of utensils, the wearing of clean overalls, and the observance of personal cleanliness. Urban authorities should be empowered to follow the cattle from their districts when sent to summer grazing outside, and the milk supply of urban districts should be controlled by systematic bacteriological examination. The committee feels that in view of the competition of other countries it is essential that the cattle and dairy products exported from the Free State should be of the highest standard and free from all suspicion of disease, but regards the problem, however, as one of perplexing difficulty. Complete eradication from the herds would be the ideal solution, but in view of the enormous expense that would be involved the question must be approached with due regard to the resources likely to be available. From evidence submitted it was thought probable that Irish stocks generally had a comparatively low percentage of infected animals, and that many of the small herds may be entirely free. The introduction of a system of graded milk is recommended, and it is thought that two grades should suffice at first: "Grade A (tuberculin tested)" and "Grade A." The sale of pasteurized milk should be permitted only in accordance with defined conditions, and persons employed in the production of graded and pasteurized milk should be medically certified. The proposals in regard to graded milk, which must be produced by a tubercle-free herd, if adopted, would have an important effect in the eradication of tuberculosis in cows, and it is recommended that milk producers should be encouraged to work towards this end by the provision of free tuberculin

testing by the Government until their herds are clear from the disease. Section 4 of the Infections Disease (Prevention) Act, 1890, should be amended to permit of the suspension of the sale of milk on epidemiological evidence, the requirement of a justice's warrant should be dispensed with, and compensation should be allowed in a case of unjustifiable suspension. There should be a penalty for selling dirty milk, and the cancellation of the vendor's licence should follow three convictions.

## England and Wales.

### Maternal Mortality: Proposed Committee of Investigation.

A scheme for the initiation of a systematic investigation of all maternal deaths and of all cases of puerperal fever, with a view to ascertaining more exactly the actual causes which lead to maternal mortality, is outlined in a circular (No. 888) addressed by the Ministry of Health to the authorities responsible for maternity and child welfare schemes in England. The circular reiterates the concern which the Minister feels because of the continued high level of maternal mortality, and directs attention to the report by Dame Janet Campbell, issued under the title of *The Protection of Motherhood*, which was reviewed on December 24th and 31st, 1927 (pp. 1198 and 1235), expressing the opinion that much remains to be done in certain areas to improve the maternity service. Reference is then made to Circular 517, issued in June, 1924, in which the importance of investigation of the kind now contemplated was emphasized, and it is suggested that the fact that the proposal then made has been adopted in very few areas is due to the failure of local authorities to appreciate the practical value of such inquiries. The Minister, therefore, explains that his object is to obtain a mass of information, hitherto not available, as to the causes of death in a large number of cases of maternal mortality, and mentions that the British Medical Association has expressed general approval of the objects. The responsibility for the investigations, it is suggested, should be undertaken by a medical officer of health of experience in these matters who is not himself engaged in private local practice. It is the Minister's intention to set up a representative Maternal Mortality Committee, somewhat on the lines of the Cancer Committee, which will be invited, among other duties, to draw up a questionnaire as a basis for the investigation, to collate and classify the information received from this and other sources, to formulate conclusions from this information, to indicate desirable lines of further research, and to advise what action can be taken to bring about a progressive reduction of maternal mortality. He hopes that it will be found possible to commence the inquiry at an early date, and to furnish reports, covering the results of the previous three months, to the Ministry of Health at the end of each quarter. The circular concludes by stating that to obtain results of any value the co-operation of medical practitioners, the maternity and child welfare authorities, and the Ministry is required, and that the Minister is counting upon the support of the local authorities in this effort to reduce one of the saddest features of our social life.

### A Post-Graduate Course for Midwives.

A post-graduate course for midwives—the first of the kind to be held in the West of England—was held at Plymouth from April 16th to 20th inclusive, the arrangements being made by Dr. A. T. Nankivell, medical officer of health. The course was open to all midwives of Devon and Cornwall, whether practising or not, the fee being half a crown. The Mayor of Plymouth (Mr. W. H. J. Priest) welcomed those who participated and expressed the hope that such a conference would become an annual event, so that problems could be freely discussed and modern methods assimilated. The course consisted of a series of five lectures: Dr. Nankivell spoke on how the State helps the midwife; venereal diseases were dealt with by the venereal diseases medical officer (Dr. Kettlerell), and lectures on ante-natal work and the expectant mother were given by the maternity and child welfare medical officers (Dr. M. Smellie and Dr. Mildred

Thynne). Visits were made to the various ante-natal clinics and infant consultation centres in the borough, the light clinic, and the venereal diseases clinic. There were sixty-four entrants, and fifty-eight of these obtained a certificate. In addition to the lectures there were many informal talks between midwives and medical officers, which proved valuable in promoting the interchange of ideas.

## Correspondence.

### TREATMENT OF GASTRIC AND DUODENAL ULCERATION.

SIR,—To quote actual figures in a communication dealing with a clinical problem, where scientific precision in measurement is not possible, where results are so often to be gauged only by subjective sensations, where so many factors are not within the control of the observer, sometimes tends to obscure rather than clarify the outlook.

Mr. A. J. Walton (April 21st, p. 688) objects to my estimate of the mortality of gastro-jejunostomy. His record of 150 cases without a death could only be attained by a superb operator. But however skilful a surgeon may be, certain factors beyond his control may play their part and vitiate his results: pulmonary embolism, the insufflation of a plug of mucus down the trachea, exposure to external infection after operation, may all occur. Nevertheless, Mr. Walton's results must mean that he is scrupulously careful over minor details. Possibly it is attention to the hygiene of the mouth, possibly some quite small point of technique, or it may be great care in the selection of cases to which his success is attributable. A minute description of his operative procedure from his own pen might throw some light on this question.

Mr. Walton has also been fortunate in his experience not to have seen a duodenal ulcer persist after a well-performed gastro-jejunostomy. Such persistence has been recorded, among others, by Sir John Bland-Sutton, Sir Berkeley Moynihan, von Haberer, M. Friedmann, A. Troell, E. Klein, and myself. Two recent cases may be briefly described.

*Case 1.*—A male, aged 49. Gastro-jejunostomy for duodenal ulcer was performed on October 5th, 1924, at another hospital. Symptoms returned and a gastro-colic fistula formed. A second operation was performed on February 20th, 1928. A well-placed, adequate gastro-jejunostomy was present, a gastro-jejunal ulcer opening into the colon, a scar on the front wall of the pylorus, and an open ulcer on the posterior wall of the duodenum, the floor of which was formed by the pancreas.

*Case 2.*—A woman, aged 52. Gastro-jejunostomy was performed by myself in 1924 for duodenal ulcer. She had relief for nearly a year and then a return of symptoms. At a second operation, on March 26th, 1928, the anastomotic opening was well placed, of adequate size, and functioning. Three ulcers were found to be present: (1) on the lesser curvature of the stomach, (2) on the front wall of the first part of the duodenum, (3) on the posterior wall of the second part of the duodenum.

As for the liability of hæmorrhage occurring despite a gastro-jejunostomy for the cure of a duodenal ulcer, my statement was based upon the careful records of J. Holbaum. Other observers also have noted the fact that such hæmorrhages may occur, though the figure given may be less.

If Mr. Walton would perform a series of partial duodenectomies for duodenal ulcer and compare them with a like series of gastro-jejunostomies, using the same standard of cure, he would find that the excision operation gave the considerably better results I recorded in my paper.—I am, etc.,

London, W., April 21st.

CHARLES A. PANNETT.

### GASTRIC SECRETION OF NEUTRAL CHLORIDE.

SIR,—The two papers on the above subject by Professor MacLean and his colleagues have now appeared. However, I do think that it is worth while reverting to the two pieces of work by Hausman, Day, and Clifton, and by Campbell, Baird, and Hern, that I mentioned in my previous letter (March 17th, p. 469), because, in spite of Dr. Goodhart's doubts, they do seem to me to have a bearing on this subject, and they have evidently been missed by Professor MacLean in his review of the literature.

In the first place it is clear that if the data on which Hausman, Day, and Clifton make their calculations are

correct there must be an addition of chloride to the stomach other than that supplied by the gastric juice, saliva, or by means of regurgitation from the duodenum.

In the second place Campbell, Baird, and Hern's experiment on caso M. B. in the *Guy's Hospital Reports*, vol. 74, p. 34, Fig. 5 (1924), shows that apparent neutralization of the gastric contents took place even though all the fluid in the duodenum was being removed by suction. The fact that this latter fluid was bile-stained, while the gastric contents contained no bile, shows that actually no regurgitation did take place.

There are two ways of accounting for this finding: (1) that the stomach was supplied with chloride apart from the gastric HCl, as was suggested by Hausman's calculation, or (2) that the pyloric mucous membrane itself produced alkali which neutralized the acid. It is true that the authors favour the latter view; but it is worth seeing where it leads us to by calculating the state of affairs in the gastric contents at the end of this experiment—that is, at one hour thirty-seven minutes. Taking the true or active HCl as the average of the total and free acids (as recommended by them in Appendix 2) we find that 100 c.cm. of gastric contents were equivalent to 17 c.cm. N/10NaOH, and contained 0.06 gram Cl. Similarly, there was 0.29 gram Cl as total chloride, and the mineral chloride was the difference—namely, 0.23 gram Cl; 0.343 gram  $\text{Na}_2\text{CO}_3$  would have been required to produce this mineral chloride from the gastric HCl. We will assume, with Hansman, that pure gastric juice (containing 0.5 per cent. HCl or 0.486 gram per cent. Cl) was being secreted by the stomach at this point, and that this and the alkali required to neutralize it were the only fluids present, while the fluid of the meal had been passed into the duodenum. Then the alkali must have diluted the gastric juice in the ratio of 29 to 48.6—that is, 59.6 c.cm. were diluted up to 100 c.cm., which means that the neutralizing alkali containing 0.343 gram  $\text{Na}_2\text{CO}_3$  was contained in 40.4 c.cm. of fluid, so that the stomach secreted a juice containing 0.85 per cent.  $\text{Na}_2\text{CO}_3$ . This is well above the highest estimate given for the alkali of the pancreatic juice, which surely is a *reductio ad absurdum*. Further, it is very unlikely at this time either that the gastric juice was really up to full strength, or that if it were there was not some dilution of it with the fluid of the meal, since starch had only been absent for seven and a half minutes. Either of these factors would tend to still further concentration of this hypothetical neutralizing fluid.

Turning now to the state of affairs in the duodenum, the authors found that the concentration of Cl was actually greater than in the stomach. It is difficult to see any other reason for this than that some absorption of fluid was taking place. Apart from this, the duodenal contents only varied from the stomach contents by the addition of bile and by the addition of further alkali, so that the free HCl had now disappeared. Calculation shows that 0.09 gram  $\text{Na}_2\text{CO}_3$  would be required to neutralize the remaining HCl (containing 0.06 gram Cl) in 100 c.cm. of gastric contents. Assuming that this was provided entirely by the pancreatic juice of 0.7 per cent. concentration, it would mean that 100 c.cm. of gastric juice would only require 13 c.cm. for its neutralization. Something extra might be allowed owing to the fact that the duodenal contents were probably actually alkaline; but it is impossible to imagine in this case that the stomach provided 40 c.cm. of a very strong alkaline fluid, and the pancreatic juice about one-third of this amount. One would wonder that the alkaline function of the pancreas had been developed at all if this state of affairs was at all common.

We are thus left with Hansman, Day, and Clifton's explanation, that the stomach was receiving a store of mineral chloride, as the more reasonable explanation of Campbell, Baird, and Hern's experiment.

Finally, this explanation, which surely must imply a secretion of sodium chloride by the gastric mucous membrane, is compatible with the high chloride in the duodenum found by Campbell, Baird, and Hern. I do not see how otherwise this is to be explained, apart from the impossible neutralization hypothesis detailed above.—I am, etc.,

London, W., April 19th.

E. P. POULTON.

## STREPTOCOCCI AND PUERPERAL SEPSIS.

SIR,—Professor Beattie's letter in your issue of April 14th (p. 642) raises questions of considerable theoretical and practical interest. He states that recent work conducted in his laboratory has shown that the action of antiseptics on different organisms varies in a marked degree, and that an antiseptic which may be efficient for *B. typhosus* may be quite inefficient for other organisms.

This statement affords important and valuable confirmation of a generalization published from this department by Professor Dreyer, Mr. S. G. Kriegler, and myself many years ago, and communicated to the Pathological Society of Great Britain and Ireland at its meeting in July, 1910.<sup>1</sup> Further detail of the work was elaborated and carried out by Kriegler under our direction, and was published by him in 1911.<sup>2</sup> In his paper comment was made as to the value of the Rideal-Walker test, to which Professor Beattie refers as the "usual standard."

In our work the conclusion emerged quite clearly that a test of a single organism, or group of organisms, with any given antiseptic against carbolic acid affords no criterion whatever as to the value of that antiseptic against other organisms or groups of organisms. I quote the following from Kriegler's "conclusions":

"... it is not possible to conclude that because a particular antiseptic is very active against a particular variety of micro-organism, it will necessarily be active against another micro-organism of a different variety."

It is satisfactory to learn that this important problem is again receiving attention in the work which is being done in the University of Liverpool.—I am, etc.,

E. W. AINLEY WALKER.

Sir William Dunn School of Pathology,  
Oxford, April 19th.

## THE FRACTURE PROBLEM.

SIR,—In your issue of April 14th (p. 636), in reference to the Fracture Committee of the American Medical Association and American College of Surgeons, it is stated that "until a similar inquiry has been made in this country it is not possible to state whether our methods are more satisfactory or not." The writer seems to have overlooked the fact that a committee was appointed by the British Medical Association in 1910, and the report of that committee was in due course published in the *British Medical Journal* (1912, vol. ii, p. 1505). Although the report is now sixteen years old, I venture to think that it contains much information of value, and that its conclusions are in the main still valid.

One important truth in particular was demonstrated by the investigations of the committee, and that is, the importance of securing a good anatomical result. While it is true that in some instances a good functional result may be obtained in spite of a bad anatomical result, such a happy issue is the exception, not the rule. This was summed up in conclusion No. vii of the report, which states: "Although the functional result may be good with an indifferent anatomical result, the most certain way to obtain a good functional result is to secure a good anatomical result."

The teaching that a good functional result is the ideal to be aimed at, no matter what the anatomical end-result may be, is fallacious and misleading. The ideal to be aimed at is a good anatomical result, and a good functional result will follow.

In many cases it is impossible to obtain a good anatomical result except by operative measures, and it is of interest to note that in paragraph vi of the Fractures Committee report it is stated that "In nearly all ago groups operative cases show a higher percentage of good results than non-operative cases."

As regards treatment by massage, I was one of the members of the committee who visited Paris to investigate the results of that treatment by the methods of Lucas-Championnière. It is not an exaggeration to say that we were profoundly disappointed at the results shown to us. I am quite aware that the expression "treatment by

<sup>1</sup> *Journ. Path. and Bact.*, 1911, vol. xv, p. 133.

<sup>2</sup> *Centralbl. f. Bakt., Parasit., und Infect.*, 1911, Band 59, s. 481.

massage" now means something very different from the methods used ten years ago; nevertheless, current views as to what exactly massage means are very conflicting. So far as the long bones are concerned, massage without immobilization is not a satisfactory method of treatment. The conclusion of the Fractures Committee on this matter was as follows:

"No method, whether non-operative or operative, which does not definitely promise a good anatomical result should be accepted as the method of choice. For this reason mobilization and massage by themselves have not been found to secure a high percentage of good results."

—I am, etc.,

London, W.1, April 17th.

HERBERT J. PATERSON.

\*\* We had not overlooked the Association's Report on Fractures of sixteen years ago, but on consideration we did not refer to it, because it did not seem to be relevant to the problem under discussion. If Mr. Paterson will read again the passage he criticizes he will find that it runs: "Until a similar inquiry has been made in this country it is not possible to state whether our records are more satisfactory or not"—meaning the way in which they are kept, as the context shows.

#### DEAD AND INFECTED TEETH.

SIR,—I am a little surprised that Mr. A. P. Bertwistle's admirable and exceedingly important article on dead and infected teeth has, so far as can be judged from your correspondence column, not attracted much attention. The role of dental infection in the production of innumerable metastatic bacterial diseases has long been recognized, thanks to the pioneer work of Dr. William Hunter. And yet there can be no doubt as to the general attitude of scepticism held by medical men as to the efficacy of eradicating dental disease in the treatment of these conditions: it is amply supported by the clinical experience of hordes of patients who have been edentulated without obvious benefit. Mr. Bertwistle rightly points out that it is the wrong type of dental infection that is looked for in such cases. It is not the case with profuse pyorrhoea; nor—and here I am in strong agreement with Mr. Bertwistle—is it always the case in which radiograms show rarefaction about the roots.

The stopping of teeth in which the pulp cavity has been infected is a surgical heresy, and I would like to put forward the suggestion that it is the duty of the medical profession to discountenance the procedure.—I am, etc.,

London, W., April 23rd.

C. JENNINGS MARSHALL.

#### THE TYPE OF TUBERCULOUS LESIONS IN BONES AND JOINTS.

SIR,—The article by Dr. Cobbett on the type of tubercle bacillus in tuberculous lesions in bones and joints in your issue of April 14th (p. 626) is of interest in many directions, not the least being the focusing of attention upon the practical importance of the parts played by two types of tubercle bacilli in the production of extra-pulmonary lesions in the human body.

Workers in sanatoriums and tuberculosis officers are privileged in their knowledge of families, and many children of their tuberculous adult patients pass, in course of time, through their hands. As a purely clinical observation one knows that the human type bacillus is the probable infecting organism in a majority of the cases of non-pulmonary tuberculosis seen in these children, and it is surprising in how many cases (apart from one's actual knowledge of phthisical parents) one can get a history of contact with infected adults. It is not altogether a case, as some seem to think, of a different bacillus producing a different form of disease; both can produce exactly the same clinical type of disease. It is rather a case of the different susceptibilities of tissues to a generic infection at different ages, and our knowledge on this point is vague.

The cow must be viewed in a reasoned perspective. So must the tuberculous adult (including the sufferer from lupus, whose capacity for damage is often entirely overlooked by those who treat him), and the public, unfortunately, is being educated to mistrust the former more than the latter.

The question of the relation of the numbers of tubercle bacilli in the discharge from tuberculous joints to the prognosis is of interest.

Late in November, 1925, a man 56 years of age was admitted to East Fortune Sanatorium, suffering from tuberculous disease of his right sacro-iliac joint. The history was of fairly short duration, and he died early in February of the following year. I have never known a tuberculous patient to suffer such pain as he experienced, and his course was one of progressive emaciation and asthenia. In January I obtained from a swelling on the posterior aspect of the joint some blood-stained fluid, which contained multitudes of small particles of tuberculous granulation tissue, in which tubercle bacilli were present in enormous numbers.

This patient's death was from disease of his joint. There were no complications, and, in fact, no other clinically detectable areas of disease.—I am, etc.,

East Fortune, East Lothian, April 14th.

C. CAMERON.

SIR,—Dr. Louis Cobbett's article should do much to correct the erroneous view held by so many people as to the relative importance of the human and bovine type of tubercle bacillus in bone and joint lesions.

In this connexion I should like to draw attention to an investigation<sup>1</sup> which Drs. Edington and Guest of Sheffield University kindly made at my request. They determined the type of organism in 38 of my bone and joint cases. Of these 7 were in the age group 0-5 years; 12 in the age group 5-10 years; 14 in the age group 10-16 years; 5 were adults. Only 2 cases, both in the age group 10-16 years, were infected with the bovine type of organism; thus the figures show that only 6 per cent. of cases in the age group 0-16 years were so infected.

When comparing this low percentage of bovine infection as found in Sheffield with the much higher figures given by other observers, especially in Scotland, Edington points out that this seems to have some relation, first, to the small amount of milk consumed in Sheffield, and secondly, to the lower incidence of tuberculosis in cows as evidenced by the small number of infected milk samples found in Sheffield compared with those in other areas—for example, Edinburgh.

These points are brought out in the following table:

	Edinburgh.	Sheffield.
Percentage of bovine infection in bone tubercle in children ...	26.3*	6.0
Pints of milk consumed per head per day ...	0.42	0.27
Percentage of mixed milk samples found to contain tubercle bacilli ...	20.0†	7.5

\* Griffith, 1916.

—I am, etc.,

C. LEE PATTISON, M.B.,  
Medical Superintendent, King Edward VII  
Hospital, and Surgical Tuberculosis  
Officer, Sheffield.

April 20th.

#### EARLY DETECTION OF TUBERCLE BACILLI.

SIR,—To the excellent suggestions made by Sir James Dundas-Grant in your issue of April 14th (p. 627) I would add an examination of the faeces. Frequently where there is no sputum expectorated much is swallowed. If it contains tubercle bacilli these will be found in the faeces. Tubercle bacilli in the faeces, provided food containing tubercle bacilli is not being eaten, is almost pathognomonic of pulmonary tuberculosis. There is for practical purposes no difficulty in this examination, and I have found it of great clinical value. The tubercle bacillus is the only acid-fast and alcohol-fast bacillus likely to occur in the faeces. The bacillus may occur in great numbers when there is little or no sputum, and this probably explains the tuberculous rectal fistula which may precede the obvious manifestations of pulmonary tuberculosis by two or three years.—I am, etc.,

F. G. CHANDLER, M.D., F.R.C.P.

London, N.W.1, April 17th.

#### EFFICACY OF TUBERCULIN THERAPY.

SIR,—Dr. Weatherhead (April 7th, p. 611) very rightly emphasizes the necessity of a control series in adjudging the efficacy of treatment in tuberculosis, but his implication that such investigations have gone to prove that tuberculin is useless calls for challenge.

Kremser chose 110 patients expectorating tubercle bacilli, treating 55 with tuberculin; they were not selected,

<sup>1</sup> Study of tubercle bacilli isolated from cases of surgical tuberculosis (chiefly bone and joint) in the Sheffield area, by J. W. Edington and D. Guest: *Journ. of Hygiene*, vol. xxv, No. 1, February 27th, 1926.

but were placed in the groups alternately as they were admitted. Of those treated with tuberculin, 22, or 40 per cent., lost their bacilli; of those treated without tuberculin, 16, or 29 per cent. Such an investigation would appear to fulfil the requirements specified by Professor Karl Pearson. Trudeau found that incipient cases did well with or without tuberculin; of moderately advanced cases 27 per cent. were cured and 55 per cent. arrested when treated with tuberculin; of cases not treated with tuberculin 6 per cent. were cured and 51 per cent. arrested. Turban found that of 86 patients whose sputum contained tubercle bacilli, and who were treated with tuberculin, 52.3 per cent. were capable of work one to seven years after discharge from sanatorium; whereas of 241 whose sputum contained bacilli and were not treated with tuberculin, only 39.4 per cent. gave a similar result. Ritter similarly ascertained the working capacity of patients one to four years after discharge from sanatorium. His figures are as follows:

Treated—	Percentage of Patients at Work.		
	Stage I.	Stage II.	Stage III.
(1) With tuberculin	95	82	50
(2) Without tuberculin	72	57	22

Lawrason Brown, working with large series of cases at Saranac covering a space of fifteen years, finds a small but definite and constant bias in favour of the tuberculin-treated cases, especially those with moderately advanced disease; he uses only small doses of tuberculin.

The investigation at Midhurst, referred to by Dr. Weatherhead, is frequently quoted as being definitely and conclusively condemnatory of tuberculin; from a study of the actual figures it is a little difficult to see how such definite conclusions can be drawn. Thus, with regard to loss of tubercle bacilli from the sputum, the figures during 1911-13, the tuberculin era, were 22 per cent. In 1908-11, without tuberculin, the figures were 15 per cent. Dr. Bardswell, in his conclusions, dismisses this difference as insignificant, but in any case it certainly does not appear to be damning. He however, proceeds to suggest that even this small advantage cannot be attributed to tuberculin, the improved results being due to the fact that patients were kept under treatment for a longer period during 1911-13. A study of the actual figures discloses that the length of stay in the sanatorium during 1908-11 varied from 14.4 to 20.2 weeks, the average being about 18 weeks. From 1911-13 the stay varied from 16.8 to 24.7 weeks, the average being about 19.5 weeks. It seems unlikely that this extra period could seriously have affected the results. Dr. Bardswell further suggests that the improvement of figures in 1911-13 is due, not to tuberculin, but to the introduction of the Ellermann and Erlandsen method of staining for tubercle bacilli. He suggests that, since tubercle bacilli can by this method be demonstrated in early cases, these swell the favourable figures. It is difficult to see how this factor seriously influences the statistics; in the first place, there is no general agreement among tuberculosis experts that the method of Ellermann and Erlandsen is so manifestly superior to the older method; secondly, even if one allows the superiority of the method, it would "cut both ways," in that it would make it equally difficult for a patient to pass out with his sputum labelled bacilli-free. Last there should still be any bias in favour of the tuberculin-treated cases, Professor Karl Pearson suggests that "perhaps the cases admitted during those years were of an unusually favourable type."

Nine Midhurst patients who were discharged bacilli-free continued with tuberculin treatment. Of these, 6 continued bacilli-free and the remainder kept well. Of 30 similar cases who did not continue with tuberculin, only 12 kept bacilli-free, 5 relapsed, and 1 died. Dr. Bardswell appears to have been largely influenced in his unfavourable opinion on tuberculin by bad results obtained in 10 particular cases, which he quotes in full. It seems exceedingly doubtful, from a study of these cases, whether tuberculin had anything at all to do with the unfavourable results. With his dictum that tuberculin is incapable of turning an unfavourable case into a favourable one, one must, unfortunately, agree; it is not a "cure," any more than diet or fresh air is a cure—it is merely a favourable factor. The figures quoted, and many others besides, show that tuberculin

therapy stands by the permanency of its results in cases with a certain degree of natural resistance. There is too much tendency among tuberculosis experts to take a light and easy view of the favourable case "who will do equally well with any kind of treatment—or lack of it." If these favourable cases can be permanently arrested and saved from relapse, is not the work worth doing, and economically sounder than the elaboration of brilliant surgical operations for the temporary salvation of desperate cases?

Everything goes to show that the sanatorium system is indispensable, but inadequate. There is strong evidence that the results of the system could be made more lasting by the reintroduction of tuberculin therapy in the sanatoriums and the continuation of tuberculin therapy by means of a dispensary system after discharge. That such treatment of ambulatory patients is practicable with safety and efficacy has been demonstrated beyond doubt by Cmae Wilkinson in this country, by Gillespie in Ireland, by Miller in New York, and other workers. It may be added that the work of Cmae Wilkinson not only shows the safety of tuberculin therapy in ambulatory patients, but also the safety of maximum doses. No others, at any rate in this country, have seriously tested the possibilities of the system of high dosage. The results at Midhurst might have been conclusively in favour of tuberculin if treatment had been pushed to the point of high dosage.—I am, etc.,

T. WARWICK PRESTON, M.D., M.R.C.P.

London, W., April 13th.

#### BLOOD GROUP PERCENTAGES.

SIR,—In your issue of March 31st (p. 546) Dr. Altounyan of Aleppo contributes an analysis of blood group percentages for Arabs, Armenians, and Jews, and remarks that they "represent well-defined unmixed racial groups." Here we have again the familiar confusion between "race" and nation or people.

The Jews, by their own accounts, have proselytized freely both before and after the dispersion, and the Armenians, by reason of their geographical position and vicissitudes, can hardly have kept their Hittite germ-plasm intact, if that in its origin were racially pure. The Arabs are notoriously a racial mixture.

Dr. Altounyan also mentions the Kurds as a folk "about whom, ethnologically, little is known." On the contrary, it is well known that the Western Kurds are a blonde, dolichocephalic folk, speaking an Aryan dialect, and are therefore probably an outlier of the Nordic race—inhabiting, I may add, a plateau with climatic conditions of low rainfall, a dry summer, and a bright frosty winter. These conditions, I pointed out years ago, closely resemble those in which the Nordic type was evolved, and therefore may account for these people maintaining their racial traits, despite their isolation. To the east the Kurds fade off into the broad-headed types of the Asia Minor highlands.

If blood groupings could be definitely correlated to the primary races of mankind, a series of fascinating problems would forthwith arise, particularly in the matter of respective morbid proclivities and reactions to environment.—I am, etc.,

J. STEWART MACKINTOSH, M.D.,

Hamstead, April 14th.

#### TREATMENT OF PROSTATIC ENLARGEMENT.

SIR,—In relation to the letter of Dr. Dennis in your issue of April 21st (p. 691) regarding the treatment of enlarged prostate by x-rays, I would like to call the attention of the profession to the great value of static electric treatment for this trouble. I would suggest that a combination of the two treatments might relieve many a case that now finds its way to the operating table.

The static treatment has proved its value for many years. It must be a quarter of a century since Dr. Snow of New York first discovered its wonderful value in reducing the size of, and relieving the symptoms proceeding from, an enlarged prostate. This treatment is simple and painless, and free from all danger. It is a wonder to me that so few medical men seem to know the value of static electric treatment in this and many other complaints.

The *sine qua non* of successful treatment is that the static machine must be sufficiently powerful. The small machines in use by the unqualified electricians are absolutely useless.

—I am, etc.,

London, W., April 21st.

ROLF CREASTY.

### THE EXPECTANT MOTHER.

SIR,—I have read with interest Dr. Statham's comments on this matter in your last issue (p. 689) in reply to my letter of March 31st (p. 571). Dr. Statham appears to be unfortunate in having in Bristol such an unprogressive council to deal with; and as one who has served for some years on municipal and county council bodies, he will, I am sure, permit me to give him a gentle lead.

At the next city council election in Bristol Dr. Statham should be a candidate, and if he runs his election on natal treatment, now that women have so many votes, he will no doubt be elected and then will be on the highway to obtain that which appears to have been so sadly neglected by the Bristol council. The method to adopt is to speak freely on the matter in open council if he is refused what is wanted in committee, and if he is a man persistent and determined in character, he will find the other members will give way, and the battle will be won; and the more shame brought upon the authority, the more will Dr. Statham be respected and admired.—I am, etc.,

Chichester, April 22nd.

ARTHUR M. BARFORD.

### THE ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—My old friend Mr. Ivor Back is pleased to be facetious. I cannot but think that if a letter is written to a Fellow one knows, advocating a candidate, in many cases this candidate will get a vote which he might not otherwise have received. If I write to my friend Ivor Back and ask him to vote for Jones, he may have a spare vote and is not quite certain whether he will give it to Jones or Smith, but as I have suggested Jones, especially if he values my opinion, he will give his vote to Jones; and if Mr. Back was going to vote for Jones I have done no harm in writing to him. On the other hand, I consider it an impertinence to write to a Fellow one does not know, so that I should strike out from Mr. Ivor Back's list Nos. 2 and 4.—I am, etc.,

London, W., April 23rd.

ERNEST CLARKE.

## Obituary.

L. R. OSWALD, M.B., C.M., F.R.F.P.S.,

Honorary Consulting Physician, late Physician-Superintendent, Glasgow Royal Mental Hospital.

We regret to record the death, on March 24th, of Dr. L. R. Oswald, who was for many years physician superintendent of the Glasgow Royal Mental Hospital, Gartnavel, and lecturer on psychological medicine in the University of Glasgow.

Lancel Rose Oswald was born on October 4th, 1861, at Blinkhony, Markinch, Fife, and spent his early youth and schooldays there. He had not the opportunities enjoyed by many other boys of his time, and it was not until after he had come to Glasgow that he decided to take up the study of medicine. Before entering the medical school of Glasgow University he had worked in an apothecary's shop, both in Markinch and in Glasgow, and during a great part of his undergraduate career he continued to assist the apothecary. His life was no easy one; he worked hard, both day and night; he had few holidays, yet nevertheless he completed his medical career with honours, and gained the Brunton Memorial Scholarship as the most distinguished graduate of his year (1888). Previously he had obtained a bursary for distinction in the first two professional examinations, and a prize for excellence in clinical medicine.

In 1888 he was appointed house-physician to Sir William T. Gairdner in the Western Infirmary, Glasgow, and held this position for a year. Dr. Yellowlees asked Sir William Gairdner to recommend a man of promise, and

without hesitation Dr. Oswald's name was suggested, so in 1889 he was appointed a junior physician at the Glasgow Royal Asylum. Following this appointment he obtained the diploma of the Medico-Psychological Association. Later he was awarded the Foulis Travelling Scholarship, and visited and studied at the laboratories of Wernicke at Breslau, Flechsig at Leipzig, and Pick at Prague, submitting the results of his research to the trustees of the scholarship. In 1895 he spent four months in the United States of America studying the system of asylum administration there, and paying particular attention to mental disorder as it affected the negro. In the same year he was appointed superintendent of the Glasgow District Asylum at Gartloch. He was responsible for the organization of that institution, and its up-to-dateness to-day is the result of his great foresight. While there he was responsible for recommending the employment of women nurses in the male wards, and exercised a great influence in raising the status of the asylum nurse. Gartloch Asylum was the first mental hospital to build a separate nurses' home for its nurses, and that was provided on his recommendation.

Dr. Oswald succeeded Dr. Yellowlees as physician superintendent of the Glasgow Royal Mental Hospital, Gartnavel, in 1901, and in 1904 was appointed lecturer in psychological medicine at the University of Glasgow. Four years later he was successful in establishing, in connexion with the Western Infirmary of Glasgow, a department for mental and nervous diseases, and was appointed consulting physician. About the same time he was among those who were particularly interested in organizing the Western Asylum's Research Institute, which has done excellent work, and attends to the needs of over 6,000 patients. He held many other appointments. At the Annual Meeting in Liverpool of the British Medical Association in 1912 he was president of the Section of Neurology and Psychological Medicine; he was president of the West of Scotland Medical Association; he served on a Royal Commission to report on the mental condition of the school children of Glasgow; and he interested himself in all movements having to do with the care and betterment of the mentally afflicted.

These are the bare facts of his career. The man himself was an outstanding personality. He was brought up in a hard school, he worked indefatigably throughout his career, and he demanded a high standard from those who worked with him. There were times when he may have been thought unduly hard and impatient, but this was soon forgotten when it was realized that everything was done and said for the best interests of his colleagues and his patients. He had acute clinical insight, and his ability to sum up a situation quickly and clearly was unrivalled. His method of eliciting the facts was almost judicial in its thoroughness, and although this cross-examining style did cause an element of uneasiness, yet it was tactfully done, and never left any resentment. It is not too much to say that his whole life was bound up in the institution which he served so faithfully for a period of twenty years, until his retirement, from ill health, in June, 1921. His heart was in his work. At all hours of the day and night he might be seen going round his wards, talking with his patients, discussing what was best to do for them, and keeping in the closest possible touch with them. They depended on him, and many will ever be grateful to him. He was not easily approachable, but he made many friends, and all admitted to his friendship were charmed by his broad understanding, his sense of duty, and his sterling worth. When off duty he was a most entertaining conversationalist, always had a fund of reminiscences and stories at his command, and enlivened any company.

As a lecturer he was able to put his knowledge forth in a clear, coherent manner. He gripped his audience, and his clinical demonstrations particularly were characterized by great force and lucidity. It was unfortunate that he did not contribute more to medical literature, as he had a happy mode of expression, and his mind was so keen, clear, and well ordered that he was able to sum up his experience in a most instructive manner. His time, however, was fully occupied. There was no department of the institution that he did not know about, he took an interest in everything that went on, and, in consequence, he handed

down to his successor a well-organized institution, which had improved and developed greatly during the time he acted as its superintendent. His advice as a consultant was widely sought and valued.

His period of ill health came on suddenly. He was stricken down while still active, and to a man of his keenness and aggressiveness a long-drawn-out, protracted illness of the type from which he suffered tried his patience to an extreme degree. He bore it with great fortitude; he continued to the last to take an interest in everything pertaining to the institution which he had served so loyally, and he was always willing to give advice and help in an ungrudging spirit.

D. K. H.

#### JOHN STEPHEN McARDLE, M.Ch.R.U.I., F.R.C.S.I.,

Professor of Surgery, University College, Dublin; Senior Surgeon, St. Vincent's Hospital, Dublin.

It was with much regret that we had to announce briefly last week the death of Mr. John Stephen McArdle, who died in Dublin on April 14th, at the age of 69, after a long illness. His death will be mourned not only by his professional confreres and a wide circle of friends, but by many poor people who had the benefit of his surgical gifts during his forty years' connexion, as surgeon, with St. Vincent's Hospital.

He was born in Dundalk in 1859, and throughout his life his interest in his native town and in the affairs of his school and collegio never waned. After a brilliant medical course as a student of the Catholic University, he obtained the diploma L.R.C.S.I. in 1879, and was appointed house-surgeon to St. Vincent's Hospital, becoming staff-surgeon two years later. In 1880 he became demonstrator of anatomy at the Cecilia Street Medical School, and obtained the licence of the Royal College of Physicians of Ireland and the licence in midwifery. Four years later, in 1884, he was elected a Fellow of the Royal College of Surgeons of Ireland, and later became a member of the council of that body. In 1900 he was appointed professor of surgery to the Catholic University, as it was then. Other positions held by Mr. McArdle were those of senior surgeon and lecturer on surgery at St. Vincent's Hospital since 1886; surgeon to St. Patrick's College, Maynooth; examiner in surgery to the old Royal University of Ireland (of which he was elected a Fellow in 1903); and consulting surgeon, Children's Hospital, Temple Street, and National Maternity Hospital, Holles Street, Dublin. At the time of his death he was president of the Irish Medical Association and a Fellow of the Royal Academy of Medicine in Ireland. He was also a member of the Senate of the National University of Ireland and of the Governing Body of Dublin University College, in which he had been professor of surgery since 1910. Despite the extent of his practice and the many calls on his time, he was the author of a number of important works on surgery.

Mr. McArdle was a man of a most genial disposition—a kindly and charitable character. By virtue of his eminence in his profession—an eminence not confined to his native country—he was always able to command and obtain large fees from many of the patients who were indebted to his great skill, but he devoted a very large part of his time to gratuitous service to the poor, particularly as visiting surgeon to St. Vincent's Hospital, and the full extent of his services in this connexion will never be known.

His principal recreations were farming and shooting, and one of his greatest pleasures in life was to retire to his charming residence at Ballyteague, in county Wicklow, after a period of arduous work, and there enjoy the rest and quiet of that beautiful mountain retreat. A close friend of the late Mr. John E. Redmond, he was a neighbour of the late parliamentary leader at his home at Aughavanna. Although he did not appear on the public platform, he not infrequently gave, by interview and by his pen, support to the claim for full recognition of Ireland's national rights. He was also an enthusiastic supporter of all branches of sport. During recent years he took a very keen interest in the transport problem in Ireland, and was president of the Irish Motorists' Association. Among the last public acts of his life was the part he took during the British coal strike in 1926 in organizing

a big scheme for the conveyance of fuel to the city for distribution among the poor, whose plight on the occasion was serious. He was twice married, his widow being a daughter of the late Mr. Michael Nugent.

#### CHARLES GREENE CUMSTON, M.D.,

Past President, International Congress of the History of Medicine.

By the death of Dr. C. G. Cumston at Chamby-sur-Montreux, on April 14th, England loses a good friend and the medical profession throughout the world one who did much to promote international good feeling. Born at Boston in 1868, he was educated at Vevey in the Institut Sillig. He graduated M.D. at the University of Geneva in 1893 on the presentation of a thesis on a subject investigated in the laboratory of Professor d'Espine, and acted for a short time as assistant to Dr. Kummer, who was then surgeon to the Butini Hospital. He married a Genevese lady, with whom he led a very happy life, for she was in full sympathy with all her husband's plans and aspirations. He then returned to Boston and specialized in surgery and gynaecology, becoming attached to several hospitals in the neighbourhood of the city. There he practised for more than twenty years, and his work was recognized by his fellow countrymen, by whom he was elected a vice-president of the American Association of Obstetrics and Gynecology. He returned to Geneva just before the war, was elected a member of the Medical Society there, and became a privat-docent in the Faculty of Medicine. He relinquished the practice of his profession and occupied himself at first in making abstracts from French and Swiss journals for the press of the United States. Larger interests soon prevailed, and he became lecturer on the history of medicine and medical philosophy in the University of Geneva. In this position he quickly justified his appointment. He filled with dignity and success the office of president at the fifth meeting of the International Congress of the History of Medicine in 1925, and in the following year he published *An Introduction to the History of Medicine*, which was well illustrated with portraits from his own collection, showing the great interest he had always taken in medical iconography.

Of late years, writes Sir D'Arcy Power, it was Dr. Cumston's practice to spend some weeks of the early summer in London accompanied by Madame Cumston, and he was thus able to keep himself in touch with his numerous friends and to spend much time at the Royal Society of Medicine, where his sympathies had been early enlisted by Sir John Macalister. He was perhaps seen at his best at his pleasant flat in the Rue Bellôt at Geneva, where he welcomed numerous visitors of every nationality with that friendly hospitality which showed that he had not forgotten the Boston tradition, for at his table there was good talk as well as good meat and drink. Nor were the wives of his friends forgotten; Madame Cumston was as hospitably inclined as her husband. He leaves no children.

Dr. F. G. CROOKSHANK sends the following tribute:

It is with great regret and a real sense of loss that many medical men in London will learn of the recent death of Dr. Charles Greene Cumston, who, though not the holder of any British qualification, was nevertheless a Fellow of the Royal Society of Medicine, and a staunch admirer of the Royal College of Physicians. At Geneva he accumulated a most excellent library concerning the history of medicine, and a really fine and beautiful collection of portraits—for the most part fine engravings and etchings—of the historic heroes of medicine. He took a lively interest in the medical life of Geneva, participating in its social side and developing the activities of the Medical Society, founding, in pious memory of two of his revered masters, the Julliard-Revillod lectures, given annually by some foreign member of the medical profession. Here too, in 1925, he had the great pleasure of presiding, in his own genial and kindly way, at the fifth Congress of the International Society of the History of Medicine. Latterly his health had somewhat failed, but several years ago he embraced eagerly the suggestion made to him by a friend that he should write in English a history of medicine, and

it was at once arranged that the volume should be included in the series known, under the editorship of Mr. Ogden, as the *History of Civilization*. The book appeared in 1926, and has already achieved marked popularity and general success. By it Cunnison's name will undoubtedly be remembered, and it is characteristic of the man. There have been, and are, many historians of medicine with greater technical equipment; there are others who are greater scholars, or who have made greater contributions to special departments of historical knowledge; but Cunnison's book is a wide and generous survey of the subject, made by a man who had practised long and successfully as physician and as surgeon, and from whom nothing human was remote or alien. In fact, just as it may be said that one of his most successful "occasional papers" was a little essay, written in French, concerning "notre sympathique confrère François Rabelais," so there was much of Rabelais in Cunnison. Not that he was Rabelaisian in the sense in which the Englishman in the street understands the term, but that, like Rabelais, an Hippocratic physician by nature and by training, and, like him too, not without experience in a speciality that reveals a great deal of what is weakest—and sometimes much of what is strangest—in human nature, and with a wide knowledge of men and things, he became a great and kind-hearted observer and critic of life—impulsive and prejudiced, tolerant and wise, philosophical and genial, caustic and kind-hearted, and above all sympathetic to everything but what is mean and despicable. And it is perhaps not altogether fanciful to trace some resemblance between two portraits now before the writer—one, a copy of the famous Geneva likeness of Rabelais; the other, a recent crayon drawing by a Genevese artist of "notre sympathique confrère," Charles Greene Cunnison.

We regret to record the death, on April 12th, of Mr. EDGAR WILLIAM WILLETT, for many years anaesthetist to St. Bartholomew's Hospital. He was born in 1856 at Brighton, where his father, Henry Willett, was well known as a collector and antiquarian. He was educated at Wellington and New College, Oxford, graduating B.A. with first-class honours in natural science in 1879, M.A. and M.B. in 1885, and M.D. in 1904. His medical studies were pursued at St. Bartholomew's Hospital, where his cousin, Alfred Willett, had lately been promoted full surgeon. After qualification Edgar Willett was appointed house-surgeon to Sir William Savory, and in 1888 he obtained the F.R.C.S.Eng. diploma with the intention of practising as a surgeon. He served for a few years on the surgical staff of the Metropolitan Hospital and of the Belgrave Hospital for Children, but becoming interested in anaesthetics he took up that branch of the profession, and was appointed anaesthetist to St. Bartholomew's Hospital. As an anaesthetist Edgar Willett was careful rather than brilliant, but no patient ever suffered any mishap in his hands from any lack of attention. In 1905 he was elected president of the Society of Anaesthetists. He resigned his appointment at St. Bartholomew's about twenty years ago and went to live in the country, but on the outbreak of the war he volunteered for service and was appointed to the Croydon General Hospital, of which he became registrar, with the temporary rank of major, R.A.M.C. On the termination of his service he retired to his house in Sussex, near Forest Row. He had a very quiet, retiring, not to say shy disposition, and consequently never had a very large circle of acquaintances, but his friends knew him as one of the kindest hearted of men, very hospitable, and ever ready to do a good turn. He enjoyed country life and was a fair golfer and shot, and ranked above the average as a croquet player, but failing health prevented him from enjoying his pursuits to the full.

We regret to announce the death of Lieut.-Colonel W. I. THOMPSON, D.S.O., which took place at Omagh, co. Tyrone, on April 12th, after a prolonged and severe illness. William Irwin Thompson received his medical education at Trinity College, Dublin, where he began his studies after serving throughout the South African war as a trooper. He

graduated M.B., B.Ch., B.A.O.Dub. in 1905, and in the same year obtained the diploma L.M. Subsequently he joined the Royal Army Medical Corps, serving at home and in India, and in 1914 was attached as medical officer to the 5th Dragoon Guards. He proceeded with that regiment to France at the outbreak of the European war, and had the ill fortune to be taken prisoner within a few weeks of landing. For eleven months he was detained as a prisoner of war, and in that period suffered considerable privation, from the effects of which he never fully recovered. On his return to England he was employed for a time in training recruits, but before the end of 1915 he embarked for France for a second time to take command of the 65th Field Ambulance. His services were recognized by the award of the D.S.O., and he was several times mentioned in dispatches. After the war he was again employed in India for several years, but in 1925 he was appointed to the Connaught Hospital, Aldershot, where he served until ill health caused his retirement. Colonel Thompson had a close family association with the medical profession. His brother was Major-General Sir Harry Thompson, K.C.M.G., A.M.S., who died in June, 1925, and whose health also was undermined by experience as a prisoner in Germany in the early years of the war. Colonel Thompson was the nephew and son-in-law of Dr. E. C. Thompson of Omagh, a former president of the Tyrone Division of the Ulster Branch of the British Medical Association. He is survived by his widow and a young son and daughter. He was interred at Portrush with military honours, detachments of his own corps and of the Royal Inniskilling Fusiliers being present.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### The Budget.

ON April 24th Mr. CHURCHILL introduced the Budget in the House of Commons. He proposed a duty of 4d. a gallon on petrol and light oils, including kerosene and turpentine, but regretted that he could not accompany it by any reduction in the horse-power tax on motors. The rate of income tax is unchanged, but the abatement for a first child is raised to £60 and for subsequent children to £50, to be allowed from the year of birth. The duty on imported unrefined sugar is reduced by 4d. per lb. Duties are imposed on lighters used in lieu of matches and on imported buttons. Mr. Churchill sketched out a great scheme of rating relief, to come into force in October, 1929. By this agricultural land will be relieved of all rates, and productive enterprises employing manual labour, together with railways, canals, and docks, will be relieved of three-fourths of the rates. The Government is establishing a fund wherewith to pay contributions to local authorities to make up for these rate reductions, contingent on the passage of a Valuation Assessment Bill after the Budget and a Local Government Bill next winter. Mr. Churchill said the latter would carry out overdue reforms in local government, and would substitute a system of block grants, quinquennially revised, for the present system of Government aid to health services and other local services. Education and police would not be included in this. For certain purposes of local government, including Poor Law and highways, wider administrative areas were needed and would be proposed. Mr. Churchill announced that in the past three years the number of officials in the civil departments had been reduced by 7,000, and that a further scheme had been prepared to suppress 11,000 more posts in five years. The defence departments were also to be examined with a view to retrenchment of staffs.

On the subsequent days this week the House of Commons continued a general discussion on the Budget. On April 23rd the House of Commons completed the committee stage of the Equal Franchise Bill, and read the Local Authorities (Emergency Powers) Bill a third time.

### Edinburgh Corporation Bill, 1928 (Venereal Diseases).

#### Second Reading Refused.

ON April 19th the House of Commons refused, by 156 to 93, to give a second reading to the Edinburgh Corporation Bill.

Mr. PETHICK-LAWRENCE moved the rejection of the bill, and said that, though a private bill, it raised issues of fundamental national importance. He said the bill would not operate more speedily to get rid of venereal disease in the country. Experience and a common-sense view of human nature convinced him that the reverse would be the case. The promoters of the bill had circulated a memorandum in which they offered to make considerable

amendments, removing the overt means whereby compulsion could be brought about. He suggested that was because they realized there were latent means whereby they could carry out their will. The promoters of the bill said it was necessary to have compulsion to catch defaulters. They had large numbers of people coming voluntarily for treatment, but before cure was completely effected a certain number defaulted. The promoters said that if they could introduce the principle of compulsion they could oblige those who came for treatment to continue coming till the cure was complete. They were mistaken. They could not graft compulsion on to the voluntary system. Under the bill there would be two classes of patients—the voluntary and the compulsory. Did the House doubt that the volunteers would be reduced in number? Those who came would perhaps have to submit, if they came to a clinic, to such a doctor as was prescribed for them, and would have to continue treatment till a cure was effected. Could the medical men in the House say whether any two medical men would agree when a cure was effected? Further, in every form of treatment there was risk and danger, and if unfortunate events occurred fewer patients would offer themselves voluntarily. At what stage would they offer themselves? Of 19,000 volunteers over 4,000 had been found not to be subject to the disease at all; but if people knew they were to be subject to a long course of treatment under compulsion they would postpone coming till the time when some of the most important opportunities for dealing with the complaint had gone. The well-to-do would consult their own practitioners, and their cases would not be notified, as there was no compulsory notification under the bill. The poor only would be dealt with, and would be informed against by the medical officer of health or by a medical practitioner. Was the practitioner to get his information from anyone who chose to assert that he or she had been infected by the person in question? That surely was preposterous. Or was the medical practitioner to get it from his personal observation in hospital or clinic? That was going to have a deleterious effect on the coming voluntarily of men and women to be treated in hospitals and clinics. The coming of mothers to pre-natal clinics would be gravely affected. The Edinburgh Corporation had issued a statement showing that in the five years from 1922 to 1926 defaulters fell from 44 per cent. to 29 per cent. of those under treatment, and this figure included those who were dead and such as seamen who could not continue the treatment. New South Wales, where compulsory treatment had been in existence some time, had only succeeded in bringing back 25 per cent. of those who defaulted. A medical conference on venereal disease in Melbourne in 1922 had passed a resolution that in its opinion there was no evidence that the compulsory venereal disease measures had resulted in any reduction of congenital venereal infections.

Dr. GRHAM LITTLE said he supported the rejection of the bill for medical reasons. For twenty-six years he had been head of two hospital departments in London where the treatment of these diseases was part of the clinic he conducted. He had sat under both Hutchinson and Fournier. The latter had now proved to be more correct in his view on length of treatment, and more prolonged treatment was now the rule for both venereal diseases. There was common ground even among medical men that early treatment was of essential importance in both diseases. The prospect of ultimate cure increased in proportion to the earliness of the treatment. It was therefore more important to get a new case than to go on treating an old one, and the Edinburgh Corporation had missed the significance of the treatment of syphilis in the importance they attached to the question of defaulters. The Trevelthick Committee in 1923 made a tentative suggestion that special measures might be necessary to deal with defaulters, but also said that default was not so serious a menace to public health as the statistics would imply. Default was decreasing, and the whole incidence of both diseases was rapidly diminishing in this country under the voluntary methods instituted in 1916. Medical opinion was overwhelmingly against compulsion. The experts on the Royal Commission in 1916 were the very flower of the profession, and their report was in favour of voluntary, secret, confidential treatment. The British Medical Association issued in 1923 a special circular to its 30,000 members, and the response was overwhelmingly against the introduction of compulsory notification of venereal diseases. Yet compulsory notification was a less serious infringement of liberty than compulsory treatment. The Trevelthick Committee, which reported in 1923, consisted largely of eminent doctors who did not know syphilis or gonorrhoea from personal medical experience, but they did support the view that compulsory measures were unlikely to secure early treatment. The Edinburgh Corporation stated that the Edinburgh Division of the British Medical Association had voted in favour of the bill. He was told that out of 1,500 persons practising medicine in Edinburgh some 60 attended, and the vote was a majority one. The vast majority of the medical profession must be opposed to compulsion, which threatened the sacredness of the professional secret. The medical officer of health for Edinburgh, who was the protagonist of the bill, suggested that the corporation was not relying on doctors, but would obtain information from a crowd of "competent officials attached to public health departments." Dr. Little presumed these officials would be asked to go round inquiring into the venereal history of the neighbourhood. He would not like to be one of those officials. Specific fevers were compulsorily notifiable, but they ran a well-defined course, which ceased at a given time, which was well recognized. The infectivity of syphilis and gonorrhoea was subject to no standard. The Trevelthick report had said: "In the present state of knowledge there is no standard of non-infectivity or cure generally accepted by the medical profession, and until this has been attained it is difficult to see how any system involving notification and compulsory measures of treatment could be applied." That was absolutely true at the present moment. The reliance to be placed on the new test and the new treatment had been greatly over-

estimated by my opinion. The test—a physiological, not a chemical one—was very difficult to apply. Detention had been ostensibly abandoned by the corporation, but he had been told by a protagonist for the corporation that they did not attach much importance to relinquishing the detention clause because they thought they could get all they wanted by the application of Section 7 of the Public Health Act, by which cases of infectious disease could be detained until infectivity was over. The bill still contemplated detention for periods which varied enormously, detention resting upon a certificate given by any medical practitioner. It was impossible at present to expect that the general profession throughout the country would be in a position to give certificates of that kind which would be of any value. The tests and the treatment for this disease required wide and highly specialized experience, and teamwork by many experts. A case presenting itself at a hospital was turned over to half a dozen people, who would go into it carefully before making any report. Was that possible anywhere in general practice? Yet they were to rely upon a certificate given by any medical practitioner, and on the treatment given by any general practitioner. Yet the modern specialized treatment was very dangerous except in highly skilled hands. He had had three dentists from salvarsan in his own personal practice. To compel persons by law to submit to these risks was an impossible proposition in the present state of medical science. Certificates given under these conditions would be largely valueless. The defaulter knew he was not cured, but the patient who was told he was cured was a source of danger to himself and the public. They could not get a system of compulsion unless it were universal. They could not confine it to Edinburgh, nor, as the Edinburgh Corporation proposed, to five years. A great success had been made of the voluntary clinics, and to destroy them by panic legislation would be a disaster.

Sir PATRICK FORD, in opening for the bill, said the mover and seconder of the motion for rejection had stated their case moderately. Edinburgh had one of the finest medical schools, with the latest methods and information, and was not going to be guided by more antiquated ways of looking at these problems. The bill had nothing to do with moral or social problems, but was to stamp out disease, and sought compulsion to deal with a residue of cases which for some years had remained steadily between 800 and 1,000—centres of infection which were going about as dangers to the neighbourhood and the country. The promoters of the bill did not suggest that voluntary work should cease, but that more power was needed to deal with a case which might be recklessly vicious and was entirely recalcitrant. He did not think the bill interfered with liberty more than any of the regulations under the Public Health Act. The opinion of the Edinburgh medical officer of health and of the officers who dealt with these cases deserved consideration. It was that the great work which was done voluntarily was to a large extent undermined by the fact that recalcitrant cases could not be dealt with. That was why they asked for these powers. There was a danger when these infected people handled food. They were a menace to society. The promoters were ready to accept an amendment deleting Clause 3 (3) of the bill (see *Supplement*, February 25th, p. 66, for wording of this clause). But Sir Patrick was willing to admit that the same power still remained to public authorities as a last recourse, by Section 54 of the Public Health (Scotland) Act, 1897, which gave power, on a magistrate's warrant, to remove a contagious case who would not submit, and have him segregated. There was no compulsory notification, no compulsory examination, or compulsory treatment. No doctor could forcibly examine any patient, man or woman; and no patient who was taken, even in the last resource, to a hospital, could be forced to take any medicine, to suffer any injections, or to have any physical treatment. The medical officer was not entitled to net on any information except from a doctor, unless he took reasonable steps to make sure. No responsible medical officer would do these things in a light-hearted manner, and if the information laid proved to be false no action for damages would lie. The safeguards were sufficient. The Royal Commission of 1916 had said: "The application of compulsion to cases in which there is no sense of responsibility, where no restraint is thought of, and where contagion is in its most active and virulent form, can be defended on strong public grounds." The Commission had gone on to say: "It is possible that the situation may be modified when these facilities have been in operation for some time, and the question of notification should then be further considered." The facilities were there, and public opinion in Edinburgh was in favour of carrying out some such proposals as the present. The views laid down by the Royal Commission had been fulfilled so far as Edinburgh was concerned. The whole weight of opinion of the local authorities in Scotland was in favour of the bill. Women's organizations in Edinburgh supported the bill, which Sir Patrick Ford asked the House to send to a committee so that its preamble could be proved.

Dr. SALZEN said he proposed to submit additional practical considerations why the House should reject the bill. It would be easy to evade its provisions by moving to another district or by giving a false name and address. People in Edinburgh who opposed the bill proposed to induce each person who applied to the clinic in future to decline to give any name other than a pseudonym. In isolation for small-pox a man was merely kept in hospital for a limited period, and, if he chose, could refuse treatment and medicine. The bill, however, proposed that persons affected with syphilis should be compulsorily treated. The method was by injection of highly toxic substances, salvarsan, or one of the later derivatives. He himself, if he had the misfortune to become infected with the disease in his professional work, would eagerly avail himself of the treatment, but would know he was accepting a great risk. Death resulted from this treatment in a considerable number of cases every year in this country. Every few weeks the medical papers reported cases of

grave accident following the treatment, and a terrible disease, known as acute yellow atrophy of the liver, followed not infrequently. Many doctors of high standing believed the old method of treatment was as effective in the long run. Apparently, by the operation of this bill one particular method of treatment, and that alone, was to be enforced, and if a patient declined that method, and demanded treatment by the older method, he was not only to be refused it, but punished for demanding it. That was an entirely new principle in British law.

Dr. FREEMANTLE intervened and asked where that provision came in the bill.

Dr. SALTER said a patient had to submit to treatment prescribed by the medical officer. That was the implication of the clause dealing with the subject. He asked the Secretary for Scotland whether, if a man suffered injury or death as the result of treatment compulsorily applied against his will, that man would not have a claim for damages either against the doctor who gave the treatment or against the institution of which the doctor was an official. Officials of the Edinburgh Corporation had met the Parliamentary Medical Committee and had supplied figures showing that in 1922 the percentage of defaulters to all persons presenting themselves was 18; in 1923, 15; in 1924, 12; in 1925, 13; in 1926, 12, and he had been told that in 1927 it was 11. That showed that the present voluntary method was effective in spite of the fact that, as he was told, the Edinburgh Corporation had only one official who followed up these defaulting cases. Before introducing such drastic proposals as the bill further efforts should be undertaken on voluntary lines, with more effective medical persuasion and an increased number of followers up. The experiment of compulsion had been made in many countries, but not hitherto in Great Britain. Dr. Salter declared that a man suffering from venereal disease who attended one of these clinics regularly might be infectious, and might remain infectious for many months, and go on spreading infection amongst the population. The bill did not propose to deal with that man, but it proposed to deal with another man who might not be infectious at all, but had simply not followed up his treatment for as long as the medical officer thought he ought to have done. He added that he would not support a bill for segregating persons suffering from venereal disease till they were declared cured. It would be ineffectual. The bill before the House would drive venereal disease underground, and there was a risk that it would increase it.

Dr. DAVIDSON SHIELS, supporting the bill, said that it was designed to fill a gap in the Infectious Diseases Acts, under which the country had possessed compulsory powers since 1889. Venereal diseases had not been brought under these Acts because till recent years their responsibility for disastrous after-effects was not realized, their specific causes were unknown, and there was no certainty of a cure. However, high medical and legal authority believed that venereal diseases could come under the operation of the Infectious Diseases Acts, and certain parts of the Edinburgh bill were identical with provisions of those Acts. With venereal disease, except in very few cases, no institutional treatment was required; the treatment might be prolonged for two years, and the patient was able during treatment to carry on his ordinary employment. Therefore the bill had been introduced because it was necessary to modify the procedure of the Infectious Diseases Acts. The Royal Commission could not recommend compulsory methods in 1916, when there were no treatment centres and comparatively few doctors were familiar with the modern technique, but that Commission envisaged a time when compulsion might be applied. The Trevelthyn Committee outlined something like the experiment proposed in the bill. The only serious argument against the bill was that it would hamper voluntary treatment and drive the disease underground. People who were most dogmatic on this question had no personal association with the treatment of the disease. Venereal disease officers, medical officers of health, and members of public health committees took another view. He was not aware that any venereal disease officer or any medical officer of health in Scotland had suggested that the proposals in this bill would harm the operation of the voluntary system. The voluntary system could go on perfectly and be supplanted by the compulsory parts of the bill, which would only be used for a small number of people. Dr. Salter and Dr. Little had spoken about terrible risks to the patient. They referred to the state of things ten years ago, and their statements were not true to-day. There had only been one death following injection in Edinburgh since 1917. Such cases were now few and far between.

Dr. SALTER, intervening, said the medical press had recently stated that over thirty such deaths had occurred.

Dr. SHIELS said he spoke of experience in Scotland. The risk was comparable to that of people dying when they had teeth drawn or in hospitals while undergoing an operation. The treatment was now so safe that a public authority was justified in using the methods proposed in the bill. Members who were medical men knew that if there was potential danger in the treatment there was absolute certainty of grave danger awaiting these people if they were not treated. Edinburgh had done everything possible to make the voluntary system a success. The Edinburgh authorities considered that the pledge of secrecy could not be easily observed if a man was sent to men in the circumstances in which most of them were placed. The men were carefully followed up by letter, and, if necessary, by calls in suitable circumstances. Edinburgh had done full justice to the voluntary system, but had many people who, careless of the danger to themselves and to other people, refused to accept treatment. Were the corporation to go on indefinitely with a system which was like pouring water into a sieve? Last year they spent over £20,000 on treatment of the disease. The estimates of the Board of Health for the treatment of this disease

in Scotland showed that £62,000 would be required next year. The local authorities had to make a contribution which raised the total to over £87,000. In the whole of Britain they were spending over £300,000 to provide free treatment and skilled specialists with a view to stamping out the disease as a part of preventive medicine. The doctor's ideal was preventive medicine, and he looked forward to a time when he would not be curing disease, but, instead, would be keeping people well. Our general hospitals, our Poor Law hospitals, our asylums, our prisons, were largely filled with the end-products of this disease recorded under the names of different conditions. The expert of the Ministry of Health on this subject, at the recent Imperial Conference at Wembley, estimated that the treatment of venereal disease at the present time saved £50,000 a year in asylum expenses, and, if treatment could do that on only one aspect of the end-results of this disease, what would entire prevention achieve? Compulsion and early treatment would prevent many of these late developments and release many beds in our ordinary hospitals. Medical officers of health and venereal disease officers denied that compulsion would drive the disease underground and send people to quacks. His experience, which was confirmed by all clinical officers, was that the great bulk of the patients were eager to get well and gave no trouble at all. Under the new provisions these people would not be affected by the knowledge that compulsion would be used on others of a different mentality. The people who defaulted did not come to the clinic because they were weak-minded or frivolous or utterly careless and irresponsible. If compulsion brought any change in the voluntary attendance it would have a good effect. At present the public did not sufficiently realize the seriousness of venereal disease, and the fact that there were no compulsory powers in connexion with it impressed on the public mind the idea that venereal diseases were not so serious. With regard to treatment by quacks, it had been illegal and a serious offence since 1917 for any unqualified person to treat venereal disease. Dr. Shiels said he was surprised at the action of some women's associations against the bill, and at the unscrupulous use made of the name of Josephine Butler. To say that the bill was analogous to the Contagious Diseases Acts of the middle of the last century was an insult to the citizens of Edinburgh. In modern days prostitutes did not form a large percentage of the patients. If they became infected they were eager, for obvious reasons, to get cured. Women's societies who objected to the bill might seriously consider the case of the innocent children, of whom between 200 and 300 attended the Edinburgh clinics—children who should have been born healthy, but who had been condemned to suffer the stigma of this disease. The bill did not abolish class distinctions, but all types of people attended the clinics, people of all social grades. The compulsory methods in Europe had only been used against prostitution, and had no reference to the system suggested in the bill. In Germany, however, a system had been introduced a few weeks ago on the lines of the bill. In Toronto a similar system was working, and less than 2 per cent. of prosecutions was needed to make it effective. He himself had investigated the system in all the States of Australia, and had a special interview with the director of medical services in Melbourne on the subject. They were perfectly satisfied with the system, and there had never been any demand for doing away with it. Dr. Shiels understood that the Government opposed the bill because it was local and not general. The Scottish Board of Health had more than once spoke of the need for compulsory measures. The English Ministry of Health, however, had always seemed to have a curious prejudice against any legislation on the subject. There was nothing in the private bill argument, because much of the general public health legislation had been built up by local experiment. Even the Infectious Diseases Act of 1889 was in operation in Edinburgh for ten years before it became a general Act. Compulsory notification of tuberculosis was in force in many towns before it became general.

Sir JOHN GILMOUR said that as the Minister responsible for public health in Scotland he approached the bill without technical knowledge, but feeling that it deserved the closest consideration by the country and the House. He regretted that he would have to advise the House to reject it. He did so after careful consideration with his advisers. Letters and communications had been cited from the Board of Health which referred to the possibility arising of using compulsion, but these communications had been made before the issue of the most recent reports on the problem. Venereal disease was a scourge, and they must make as great progress as possible towards eliminating it, but the measure of progress must always be in proportion to, and not in advance of, the volume of public opinion in support of it. The Board of Health recognized the skill with which the Edinburgh Corporation, as others throughout Scotland, had endeavoured to deal with this problem. Cases such as those cited of the deliberate infection of children rightly aroused the indignation of those who had to deal with the problem, but he asked the House whether, if compulsion were authorized, these cases could be more easily dealt with than now. The Trevelthyn Committee had said: "It has been suggested by some that in order to secure unbroken attendance of patients at clinics a modified form of notification supported by appropriate compulsory measures should be applied to those who have once attended the clinics . . . but in our view such a system would be more likely at the present time to deter than encourage attendance, and it seems difficult to justify the imposition of a penalty on those who have come for treatment while leaving untouched those who have made no effort to seek treatment." Sir John submitted that was a condition which this bill would propose to carry out. On those grounds he was compelled to say to the House that he did not think they would be wise to proceed with it.

Sir BASIL PETO asked why Sir John Gilmour implied that the bill dealt only with those attending clinics and left out all who did not attend.

Sir JOHN said it seemed obvious that unless they also had compulsory notification that would be the result. He pointed out that the Corporation of Glasgow was bringing forward proposals on different lines.

Mr. KIRKWOOD asked whether Sir John would support the Glasgow bill. (The draft of this bill proposes compulsory notification of venereal diseases.)

Sir JOHN GILMOUR: Sufficient for the day is the evil thereof. Concluding, he declared that under the voluntary system great progress had been made. The experiment proposed was bound to have effect on areas far outside that in which it was made, and if it failed, or partially failed, would have reactions which many could not foresee. He was compelled with regret to ask the House to reject the measure.

Dr. FREMANTLE said the House had that day seen the medical profession divided because of its honesty and determination to tackle difficult questions. The medical members had certain grounds in common. One was a realization of the intense seriousness of the evil they were trying to treat. The public was insufficiently aware of the seriousness of the position. The Royal Commission of 1916 had concluded that one person in ten of the whole population of our large cities was infected with syphilis, one of the great killing diseases. Gonorrhoea, one of the great crippling diseases, was equally or more prevalent. It was true that by the voluntary system the number of defaulters had been reduced, and he hoped it would continue to be reduced; but did any impartial man or woman imagine that any voluntary system was going to secure the treatment of those who were recalcitrant? The Government and those who opposed the bill were content that nothing should be done for these people. The medical profession was unanimous that the main basis of the treatment of the disease, and still more the measures of prevention, must be voluntary. All statistics from other countries were incomparable because under this bill they meant to keep the voluntary system. He had seen that system working in Edinburgh. Ten years ago it was almost taboo to mention these subjects and difficult to get anyone to appear for treatment. Now they saw the cases pouring in, sitting side by side in the general clinic, and anxious to continue their treatment. They knew its effects, they knew that confidence would be respected, that the secrecy was as absolute as it could be made. They gave their names and addresses that their treatment might be continued and a record produced if they lapsed for a time and came back. That record was confidential. One medical officer was responsible for keeping it under lock and key. The officer knew that certain people continued treatment while others refused it. At present the ones who refused, after a short space of time infected people right and left. It was often found that the wives and children who came in were all infected. The doctor knew that the man was continuing to spread the infection, and at the present time could do nothing to compel that man to continue treatment. The man's wife could do nothing, although she was being infected, to prevent more infected children being bred. The Edinburgh Corporation said, "We want to deal with that case." That was the case for the bill. The medical officer now had information through the cases of friends or relatives who came for treatment, and wrote privately to the man concerned. In many cases he could get the man to come for treatment, but a certain number would not come. This bill would enable him to say, "You must forward me a certificate that you are being treated." It was not compulsory for the man to come to the clinic even if he was poor. There were poor men's doctors to whom he could go and from whom he would get a certificate.

Dr. SALTER asked what would happen if the applicants for treatment refused to give either their names or addresses.

Dr. FREMANTLE said they would not be treated, but that would not happen. The success of this bill depended on administration and personal contact, and because the medical officers who dealt with this subject knew how to get at the people by wise means it would be a success. The measure of compulsion was kept in the background in dealing with infectious diseases at the present time. Practically no one refused to be taken to an isolation hospital, but there was the power of compulsion behind. He supported the bill as an experiment. Applications from other authorities would have to be considered on their merits.

Mr. ERNEST BROWN, an Edinburgh member, denied that there was a unanimous public opinion in Edinburgh in favour of the bill. He had refused to back it, but could not say whether his electors were for or against it. The issues raised in Clause 3 had never been discussed in public in Edinburgh. It was not a bill that should go before the Private Bill Committee.

Sir SAMUEL CHAPMAN, another Edinburgh member, said he was a sponsor of the bill, but not at present a supporter. He desired to see it sent to a select committee.

Mr. STEWART, as a member of the Lunacy Board, argued for the voluntary system. If the country decided in favour of compulsion it should be a general system.

Lady ASTOR said they had found that compulsion would not do away with this disease. The Contagious Diseases Acts, instead of doing away with disease, only increased it. Only under the voluntary system had they a chance of getting at the men and women victims. There was only one way whereby they could protect the children—by a single moral standard. In Australia the defaulters, under compulsion, had never been below 75 per cent. She gave figures showing that in Bradford, which had the powers now asked for by Edinburgh, the number of babies affected with gonorrhoeal blindness had increased since compulsory treatment was introduced. The bill was impracticable, and if any women were in favour of it that was because they did not understand it. No bill would create more disturbance in the country

than this was likely to arouse. If the bill passed it would fall more heavily on the women than on the men.

Mr. WILLIAM GRAHAM said that in preparing the bill the Edinburgh Corporation recognized that it involved a more than local issue. At the end of ten years' experience they were satisfied the case for second reading could be established. The State provided 75 per cent. of the expenditure on venereal disease clinics, and the interest of the taxpayers was to see that there was not some inherent weakness in the system which undermined a good deal of the work done. Scottish local authorities in their representative assemblies, such as the Convention of Burghs, had in recent years passed resolutions urging that some sort of compulsion was needed, and the Scottish Board of Health had in reports from 1922 alluded to the possible consideration of compulsion. The subject had been fully considered by the Edinburgh Corporation. Only two members of the corporation had dissented. In Edinburgh the voluntary system had been pursued to the utmost limit, but a list of defaulters remained, which over the last five years ran from 850 to 1,000 people, over whom the corporation had no real power to compel them to continue treatment. The lady almoner had visited a large number of cases, and was satisfied that Edinburgh had now reached a point at which this defaulting class was steady or fixed. He submitted that a case had been made out for investigation by a select committee, and that a great corporation should be allowed a chance to experiment, even by exceptional methods.

Mr. SCRYMGEOUR read a statement from Dr. Burgess, medical officer for Dundee, who said: "Our experience is such as to suggest that further powers are necessary. I find that during the last four years an average of only 36 per cent. of the patients who ceased to attend our centres did so because they were certified cured, and of the remaining 64 per cent. a very small proportion were transferred to other centres." The doctor favoured some compulsory measures, making it a legal duty on the medical practitioner to notify the disease. Dr. Burgess also held that before costly measures were introduced facilities for free treatment of all infected persons must be available to every person. Facilities must not only be of the nature of clinics for out-patients, but also of wards for in-patients.

As stated above, the second reading of the bill was refused by 156 to 93. Dr. Drummond Shiels told for the bill and Dr. Graham Little against it. Members voting against the second reading included Dr. Vernon Davies, Dr. Walter Elliot, Sir Richard Luce, and Dr. Alfred Salter.

#### National Health Insurance Bill.

A standing committee of the House of Commons commenced, on April 24th, to consider the National Health Insurance Bill. On the first clause, making amendments regarding continuous insurance, contributions by voluntary contributors, and arrears, Mr. JOHNSON proposed that after the extended period an insured person should continue to be treated as such for a further period of five years.

Mr. CHAMBERLAIN said that when he first saw this amendment he was disposed to regard it as a joke. An insured person was now entitled to one year nine months of free insurance when unemployed, and, if genuinely unable to get work, to another year, which might be further prolonged if he had been ill.

Labour members of the committee argued that special extension was required for men in the coal-mining areas, and pointed out that some trade unions retained unemployed members on the books for as long as seven years.

Mr. HARVEY pointed out that after one year nine months the unemployed man was only entitled under the original Act to cash benefits subject to a reduction, but under the Prolongation of Benefits Act, a temporary measure, he was now kept in insurance and entitled to medical benefit so long as he was unemployed. There was nothing ludicrous in proposing to make that provision permanent.

Mr. RHYNS DAVIES commented that a subsequent section provided that an insured person, of 60, if unemployed after ten years in continuous insurance, was to be treated as an insured person for five years so as to preserve his pension rights. Sir KINGSLEY WOOD said that provision was inserted at the special request of the trade union representatives on the Consultative Council. Mr. RHYNS DAVIES said that when it suited the Government policy the Government actuary could always put his hand on a few millions.

Dr. DRUMMOND SHIELS said there was no doubt that after a period of unemployment in this country men were not physically fit, and were specially liable to illness and death.

Mr. CHAMBERLAIN said that the subsection keeping persons over 60 in the scheme did not entitle them to sickness or disablement benefit. Members who supported the amendment advanced arguments which, carried to their logical conclusion, meant that all insured persons' rights should be secured in perpetuity. The representatives of the trade unions on the Consultative Council had come to the conclusion that in this clause they had got all they could reasonably expect. Under the bill, if at any time during the period of two and three-quarter years the unemployed man could get out week's work, he would start all over again. It must not be thought that even medical benefit meant no expense to the societies. People left out of the bill as it stood were only those permanently unemployable and therefore not suitable subjects for insurance.

Mr. RHYNS DAVIES remarked that the number of persons who had come into the old age pensions contributory scheme had been less than was anticipated, and there would be a surplus which he desired to retain for the benefit of insured persons.

The amendment was defeated by 18 to 15.

Mr. RHYNS DAVIES proposed that at the expiration of extended

benefit the unemployed contributor should be entitled to become, within the next year, a voluntary contributor.

Sir KINGSLEY WOOD pointed out that regulations under the 1924 Act permitted the Minister to make regulations regarding the length of time allowed for such an option. It would be better to leave this power of regulation to the Minister, who would give careful consideration to the point raised by Mr. RHYDS DAVIES. The amendment was withdrawn.

On the proposal that Clause 1 be added to the bill, Mr. RHYDS DAVIES said the clause was an improvement on the provisions of the Prolongation of Benefits Act. Nevertheless, the approved societies had been called upon to bear a burden, the result of unemployment, which really should have been carried by others. On top of that the Economy Bill had prevented the Minister from propounding the improvements in national health insurance which should have been made.

Clause 1 was added to the bill by 18 to 16.

On Clause 2 Mr. BROAD moved an amendment to the provisions for the payment of benefit to insured persons in hospitals, sanatoriums, and other institutions. The bill proposed that the money should be paid by weekly instalments. Mr. Broad argued that it would be more valuable as a lump sum on convalescence.

Mr. CHAMBERLAIN said the bill followed the recommendation of the Royal Commission, which had been approved by the Consultative Council.

Mr. RHYDS DAVIES said the Consultative Council could only express its opinion on issues submitted to it by the Minister.

Mr. CHAMBERLAIN said the Council was free to ask for anything to be referred to it, and the request was never refused. He promised to consider at a later stage the matter raised by Mr. Broad.

The committee then adjourned till April 26th.

In a reply to Sir Robert Thomas, on April 18th, Sir KINGSLEY WOOD said the average cost of drugs and appliances per insured person in 1927 in the areas of Welsh Insurance Committees was approximately 29.5d., and in the areas of English Insurance Committees 35.1d. The lower cost per head in Wales might be due to the large number of persons in the Principality who received treatment for minor complaints.

Sir COOPER RAWSON asked the Minister of Health whether his attention had been called to the report of the East Sussex Insurance Committee with regard to a case in Hove, in which it was alleged that a panel doctor was visited by a regional medical officer of the Ministry, who criticized his methods of prescribing, and that subsequently the doctor was threatened with action on the part of the Ministry unless he prescribed medicines of a cheaper character. Sir Cooper asked what was the reason for such an interference with the jurisdiction and authority of the Panel Committee.

Mr. CHAMBERLAIN said his attention had been called to the case, and he was considering the report of the East Sussex Insurance Committee. The visit of the regional officer was directed to ascertain, in accordance with the Medical Benefit Regulations, whether the case should be referred to the Panel Committee. The warning to the doctor indicated that in certain circumstances such a reference might have to be made.

Answering Captain FRASER, on April 19th, Mr. CHAMBERLAIN said that in the National Health Insurance Bill now before the House provision was made for the inclusion in the list of additional benefits of a new benefit under which approved societies would be able to make payments towards the cost of massage and electrotherapeutic treatment of their members in approved institutions. Captain FRASER asked whether massage would be a direct additional benefit or given indirectly through institutions. Mr. CHAMBERLAIN said it took the form of a new benefit, and power was given to make contributions towards its cost.

In an answer to Mr. Hardie, on April 19th, Mr. CHAMBERLAIN said he would watch with interest the experiments being made in the provision of treatment in clinics for persons suffering from rheumatism, but the Government did not intend itself to set up such clinics.

#### Foot-and-Mouth Disease.

Mr. HURD, on April 19th, suggested that Mr. Guinness should issue a regulation that in all future importations of meat from the Argentine or elsewhere the head, including the tongue, and the feet must be attached to the carcass, as the lesions which indicated foot-and-mouth disease were most apparent in those parts. Mr. Guinness said the suggested regulation would not be effective in preventing the importation of possibly infective carcasses. Animals might be killed when in the incubative stages of the disease before they developed lesions, and their carcasses did not show recognizable signs of the disease. To prevent carcasses of animals which had been killed when in the incubative stages of the disease from being imported into Britain, the Ministry of Agriculture had requested the South American Governments not only to prohibit the export to Britain of all carcasses of infected animals, but also of any animals which had been in immediate contact with them; and laws had been passed by those Governments to give effect to the Ministry's suggestions. He was confident that those laws would be effectively enforced and that they would afford a greater protection than would the regulation suggested by Mr. Hurd.

Mr. GUINNESS, replying to Mr. Hurd, on April 23rd, said that out of 91 outbreaks of foot-and-mouth disease confirmed this year in 29 cases the disease originated in pigs, but 25 of these were traced to infection from other outbreaks. Of the remaining 4 cases, in only 2 was there any evidence that infection might have been contracted by the pigs coming into contact with butchers' waste containing meat scraps of foreign or English origin, but there was

no proof that this was the source of infection. The Foot-and-Mouth Disease (Boiling of Animal Foodstuffs) Order, as amended in February last, not only made it an offence to bring any meat, bones, offal, etc., into contact with animals, or to feed them to animals, until the materials had been boiled, but also made it an offence to permit animals to come into contact with the materials until the latter had been boiled. Mr. Guinness further stated that the possibility of infection of foot-and-mouth disease in chilled carcasses had been demonstrated by the Foot-and-Mouth Disease Research Committee. The Boiling of Animal Foodstuffs Order of 1927 was designed to prevent any infection which might be introduced in this way from reaching animals in this country. He was not prepared to give instructions for the systematic testing of carcasses to prove the existence of a contingency which had been admitted and had been provided against. The Orders requiring the destruction of hay and straw used as packing for imported goods and the sterilization of meat wrappings before being brought into contact with animals were calculated to be an effective safeguard against the introduction of foot-and-mouth disease by any such materials which might be contaminated by the virus. The enforcement of these Orders was a duty of the local authorities. Nineteen prosecutions under these Orders by the local authorities had been notified to his department, resulting in thirteen convictions.

#### Sanitary Conditions in Hop-picking Camps.

On April 19th Dr. VERNON DAVIES asked the Minister of Health if his attention had been drawn to a recent address by the county medical officer of health for Kent referring to the sanitary conditions of some hop-picking camps, and the administration of certain rural district councils in connexion therewith; and what proceedings, if any, he proposed to take to remedy these conditions.

Mr. CHAMBERLAIN said this address and a report made by the medical officer of health were receiving consideration. He had no power to compel a local authority either to adopt or to enforce by-laws on this subject, but had represented to the local authorities the importance of their administrative functions in this matter. If necessary, he would continue to do so.

Dr. DAVIES asked whether, if Mr. Chamberlain's powers were insufficient to deal with the local authorities concerned, he would seek further powers in order to deal with them. Mr. CHAMBERLAIN said that depended on other considerations.

Sir KINGSLEY WOOD, on April 23rd, told Mr. Briant that though there had been an improvement in recent years he could not say that the Minister of Health was satisfied with the conditions existing in the hop fields. The reports of officers of his department, and there appeared no sufficient reason. The whole question was receiving compulsory registration of camps would ulties.

#### Registration (Births, Marriages, and Deaths) Bill.

On April 20th Captain GUNSTON moved the second reading of the Registration (Births, Marriages, and Deaths) Bill, which provided that on an office of superintendent registrar, registrar of marriages, or registrar of births and deaths becoming vacant the Registrar-General might declare the office a salaried one and see that the successor to the office received a proper salary, on a scale approved by the Treasury. The bill allowed the officers to act over a larger area, and authorized the Minister of Health to increase the fees up to 50 per cent. It also proposed to extend to all births and stillbirths the provision whereby, under the Act of 1874, if the informant removed after the time of the birth and before registration, he could go to the registrar in the area to which he removed. Captain Gunston remarked that modern conditions did not lead to increased fees for registrars of births and deaths. The aggregate of births and deaths had fallen from 39 per 1,000 in 1913 to 29 per 1,000 in 1927.

Mr. GEOFFREY PETO seconded the motion for second reading.

Mr. SCURR moved the rejection of the bill, objecting that it should have been brought in as a Government measure.

Sir KINGSLEY WOOD said every Minister of Health in recent years had been made acutely aware of the dissatisfaction among registration officers. The average total of fees per registration district was now £137 per annum, and the system bled out no promise of promotion.

Dr. FREMANTLE defended the introduction of the measure as a private member's bill. By the same method two years ago they secured the Midwives and Maternity Homes Act; last year the Nursing Homes Registration Act and the Mental Deficiency Act. Two years ago also they had passed a measure for improvement of the registration of births and deaths. This bill was connected with the last proposal. In theory the bill proposed to transfer registration from a local to a national service, but the period of transition might be very long. The power of the Registrar-General to make regulations under the bill would be subject to the approval of the Minister of Health, in whose hands the appointments would be. Social services, especially in public health, depended largely on the facts got together by the registration system of the country. The whole of vital statistics depended on it, and statistical research was based on it. The Eugenics Education Society had issued a letter in support of the bill.

Dr. VERNON DAVIES said it would be impossible to make this a whole-time service. The work of a registrar of births and deaths was almost entirely notification of facts. The records of these went in course of time to the Registrar-General, in whose office all the important work was done. Work on vital statistics had to be centralized. To increase the registration districts to

100,000 inhabitants would be impracticable, and so the service could not be a full-time one throughout the country. The building of hospitals and maternity homes had considerable effect on fees, of which Dr. Davies gave examples.

After further discussion the bill was read a second time and sent to a standing committee.

#### Protection of Dogs Bill.

Sir ROBERT GOWEN moved, on April 20th, that the Protection of Dogs Bill be read a second time. He said he had secured a second reading for a similar bill a year ago. Members from almost every constituency had assured correspondents that they would vote for the second reading this year.

Lieutenant-Commander KENWORTHY, in seconding, said he had introduced bills to prevent all living creatures being used for vivisection. He asked the House to give a second reading to the bill. Any necessary safeguards desired by the more reasonable members of the medical profession could be put in in committee.

Dr. GRAHAM LITTLE said the dog was necessary for certain experiments as it was most like the human being in its internal organs and many other parts of its body, more so than the pig. "At this point the House adjourned without any question being put, the hour of adjournment having been reached with the discussion uncompleted."

On April 19th the Marriages (Prohibited Degrees of Relationship) Bill was read a second time.

## The Services.

### DEATHS IN THE SERVICES.

Major John Drew Moir, R.A.M.C. (ret.), died in London on March 26th, aged 66. He was born in Australia, at Victoria, on September 7th, 1861, and educated at Aberdeen, where he graduated as M.B. and C.M. in 1883. Entering the R.A.M.C. as surgeon on January 31st, 1885, he became major after twelve years' service, and retired on January 30th, 1905. He was employed, when on the retired list, in Fort Efford and Matley districts from 1907 to 1913. He served in the Sudan campaign of 1885-86, in the Egyptian Frontier Field Force, was present in the action at Ginnis, and received the Egyptian medal and the Khedive's bronze star. He also served in the South African war from 1899 to 1902, in charge of the Princess Christian Hospital and of the 11th Brigade Field Hospital. He took part in operations in Natal and in the Transvaal, when he shared in the relief of Ladysmith, and was present in the actions of Spion Kop, Vaal Krantz, Tugela Heights, Pieter's Hill, and Laing's Nek. He was three times mentioned in dispatches, in Sir Redvers Buller's dispatches of March 30th, June 19th, and November 9th, 1900, and in the *London Gazette* of February 8th, 1901, and received the Queen's medal with six clasps and the King's medal with two clasps. After his retirement he was in the Reserve of Officers, and when the recent great war began rejoined for duty on August 5th, 1914. During the war he served as president of recruiting boards in London, and afterwards as D.A.D.M.S., and was again mentioned in dispatches; and later as president of the pensions boards for South London.

Lieut.-Colonel William Henry Burke, Bombay Medical Service (ret.), died at Lansdowne, Bath, on February 29th, aged 69. He was born on November 5th, 1858, the son of the Rev. Thomas James Burke of Shepton Mallet, Somerset, and educated at Trinity College, Dublin, where he graduated as B.A. in 1881, M.B. and B.Ch. in 1882, and took the D.P.H. in 1883. After studying also at Vienna he entered the I.M.S. as surgeon on September 30th, 1882, became lieutenant-colonel after twenty years' service, and retired on January 1st, 1910. He served in the Burma war in 1886-87, was mentioned in dispatches in G.G.O. No. 561 of 1887, and received the medal with a clasp. Most of his service was spent in civil employ in the Bombay Presidency, where, for some years before his retirement, he was civil surgeon of Poona, surgeon to the Sassoon Hospital there, and superintendent of the Poona Medical School. After his retirement he rejoined for service in the great war, and served in the Indian hospitals at Brockenhurst and Brighton.

Lieut.-Colonel Edwin William Reilly, Madras Medical Service (ret.), died at Llandudno on December 21st, aged 68. He was born on September 29th, 1859, the son of Edwin Reilly, medical assistant, of Calcutta, and educated in Calcutta and in Edinburgh, where he took the L.R.C.P. and S. in 1881. Entering the I.M.S. as surgeon on April 1st, 1882, he became lieutenant-colonel after twenty years' service, and retired on July 18th, 1907. After retirement he rejoined for service in the great war, and was for some time medical officer of the hospital for officers at Worsley Hall, near Manchester. He served in the

Burma campaign of 1886-88, when he took part in the operations of the 2nd Brigade, was present in the actions at Kyaukse and Sabanalath, and received the medal with two clasps. Most of his service was passed in civil employ in the small province of Berar, now amalgamated with the Central Provinces.

## Universities and Colleges.

### UNIVERSITY OF LONDON.

#### UNIVERSITY COLLEGE.

Among the public lectures arranged at University College, London, to take place during the current term is a course of three on "The pharmacological evidence for current methods of treatment," to be given by Dr. J. H. Burn; the first lecture will be on Tuesday, May 1st, and the others on the two following days, all at 5 p.m. A series of three lectures on "Anatomy and the problem of behaviour" will be given by Dr. G. E. Coghill of the Wistar Institute, Philadelphia, at 5 p.m. on May 7th, 8th, and 10th. Professor L. J. Henderson of Harvard is to give six lectures, his subject being "Blood: a study in general physiology"; these lectures will be given on Tuesday, Thursday, and Friday in two successive weeks at 5 p.m., the first being on May 15th. On Friday, June 1st, at 5.30 p.m., Professor Spearman will speak on "The psychologist in the school." All these lectures are open to the public without fee or ticket.

### UNIVERSITY OF GLASGOW.

The following degrees were conferred on April 21st:

M.D.—Muriel J. Brown, 'W. C. Harvey, 'W. A. Horne, 'W. Brown, J. W. Graham, 'W. Napier, D. O. Taylor.  
Ch.M.—D. R. E. Roberts.  
M.B., Ch.B.—J. S. M. Robertson, 'D. Fraser, 'H. H. Moyes, 'D. R. Millikan, 'Constance D. Roberts, J. Aitchison, T. R. Baird, T. Barrowman, C. Black, R. Brown, D. H. W. Cameron, J. M. Carnovsky, W. Craig, Mabel E. Cruickshank, A. F. R. Dewar, W. M. Dickson, Katherine M. Douglas, S. K. Drainer, W. Duncan, R. Duan, J. G. Dyer, T. Dymock, O. R. Gibson, L. P. Gray, A. Henderson, J. Hinds, Elizabeth C. M. Jack, J. C. Kane, J. G. Kirk, L. Lamont, H. Leslie, P. L. B. Loreat, Isabella K. A. Macdonald, Janet . . . . . , 'Arlene, Margaret I. McGill, A. I. . . . . , 'C. McPherson, A. H. W. . . . . , 'Montgomery, T. Y. Muir, J. F. . . . . , 'L. Pirrie, J. J. Reddick, J. F. . . . . , 'Robertson, J. L. D. Rod, J. M. . . . . , 'C. Taylor, W. S. Thomson, J. B. . . . .

\* With high commendation. † With commendation.  
‡ With honours.

... .. were also presented to the successful ... .. H. S. Rauken, V.C., Memorial Prize of £5, awarded to the student who obtained the highest marks in the subject of pathology in the professional examinations held in the year 1927, and the Macleod Gold Medal for surgery to J. F. Heggie; the Macleod Medal in surgery to Margaret W. Thomas; the Asher Asher Gold Medal for laryngology and rhinology to S. J. Scott.

### CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—T. Gilchrist, H. T. Chapman, Agnes Donaldson, A. P. J. C. Chitty, J. T. Erskine, J. E. Mulholland, R. D. Jones, S. K. Kapur, N. A. P. de Souza, H. A. Shakerley, J. Leibman, W. Wallace, M. R. Ramjohn, S. N. Chopra, J. P. Logan, J. Lees, L. M. Davies, Eileen M. Cane, N. Macleod, W. Allan, A. J. de Villiers, A. H. P. Amos, R. D. Buckner, A. El-Sayed Ali Ammar, C. B. Goodwin, T. Kelarkar, H. L. Cohen, C. E. Vaz, B. Singh. *Médecine*: N. S. Fraser, A. Jacorovitch, N. W. Lalag, H. W. A. Marshall, H. M. C. Silva, F. E. L. Stewart. *Surgery*: W. D. Alvis, J. Campbell, H. Gunavathana, H. Lazarus, M. Rifkin, C. K. Row, B. Schulman, O. Stern. *Midwifery*: C. Aibade, A. J. E. Almada, W. D. Alvis, A. H. F. Arnott, J. Campbell, A. M. Fraser, H. Gunavathana, A. Jacorovitch, K. Kanakasabapathy, N. W. Laing, H. Lazarus, Mary E. J. Magoo, A. H. O'Brien, B. Schulman, F. E. L. Stewart, Mary E. J. Magoo, A. H. O'Brien, B. Schulman, F. E. L. Stewart.  
H  
J  
Y  
W  
I. W. Spence, E. C. Thomas.

### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—G. E. Bent, A. E. D'Abreu, D. Jacobson, D. K. Reynolds, J. O. B. Shirley, A. E. Vasser.  
MEDICINE.—H. B. Baker, H. T. Ince, H. T. Rylance, W. Ziv.  
FORENSIC MEDICINE.—B. Elliott, J. H. Johnston, N. H. Kettlewell, E. A. Lipkin.  
MIDWIFERY.—A. E. Gibbs, C. C. F. White.

The diploma of the Society has been granted to Messrs. B. Elliott, H. T. Ince, D. Jacobson, D. K. Reynolds, H. T. Rylance, and I. O. B. Shirley.

## Medical News.

SIR BERKELEY MOYNIHAN, Bt., P.R.C.S., will preside at the first annual dinner and meeting of members of the University of London Medical Graduates Society at the Laugham Hotel, Portland Place, at 7.15 for 7.30 p.m., on Tuesday, May 8th. Any medical graduate of the University of London can join the society by sending a life subscription of £1 to the honorary treasurer, Mr. W. McAdam Eccles, M.S., 124, Harley Street, W.1.

FOUR Gresham Lectures on the need of change and the medical aspects of the health resorts of England and Wales will be delivered by Sir Robert Armstrong-Jones, M.D., at Gresham College, Bastughall Street, E.C. (three minutes' walk from the Bank Station), on May 1st, 2nd, 3rd, and 4th, at 6 p.m. Admission is free to the public.

SURGEON COMMANDER S. F. DUDLEY, R.N., will open a discussion on the problem of diphtheria control in crowded institutions at a meeting of the Naval, Military, and Air Force Hygiene Group of the Society of Medical Officers of Health on Thursday, May 3rd, at the house of the society, 1, Upper Montague Street, Russell Square, W.C., at 5 p.m.; medical practitioners interested in the subject are invited to attend.

THE Royal Society of Arts, John Street, Adelphi, W.C., has arranged two lectures for Wednesday, May 2nd and May 9th, at 8 p.m. The first will be by Mr. William Taylor on standardization in apparatus for science teaching, and the second by Captain R. W. Lane on the sterilization of milk.

A CONFERENCE, organized by the Society of Chemical Industry in co-operation with its London section and chemical engineering group and the Institution of Chemical Engineers, will be held in London from May 11th to May 15th. It has been arranged as a practical reply to a friendly challenge by the Earl of Balfour, who recently expressed his apprehensions regarding the ability of British chemists to apply scientific knowledge to industry. An interesting series of discussions has been arranged dealing with such important subjects as the economic utilization of coal, water, and air. Fuel problems are, of course, receiving an increasing amount of attention; questions relating to water supply are of great consequence to industry; the fixation of nitrogen from the air and the production of fertilizers therefrom is perhaps the greatest contribution yet made by science to agriculture. Members of the conference will have an opportunity of visiting the Rothamsted Experimental Station. The feature of greatest general interest will probably be the address to be given by Sir Alfred Mond, president of the British Science Guild, on scientific research as applied to industry.

THE Council of the Derby Medical Society has arranged a course of post-graduate lectures on applied physiology to be given at the Derbyshire Royal Infirmary by Dr. W. Langdon Brown, at 3.15 p.m., on Wednesday afternoons from May 2nd to June 6th, both inclusive. The lectures are designed to show the bearing of recent advances in physiology on the clinical work of general practice. Particulars may be obtained from Dr. G. E. Kidman, 134, Osaston Road, Derby.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that there will be two demonstrations next week, both taking place on Tuesday, May 1st, one at 1 p.m., by Mr. Goulden, at the Royal London Ophthalmic Hospital, and another at 3 p.m., by Dr. H. C. H. Bull, at the Royal Waterloo Hospital; both are open to all members of the medical profession without fee. The special course in psychological medicine at the Maudsley Hospital, as already announced, begins on Monday, April 30th, and on the same day there begins a month's course in dermatology at the St. John's Hospital, Leicester Square. Practical pathological demonstrations will be arranged if desired. Four special courses are due to begin on May 7th, occupying periods of varying duration; they are in diseases of infants, for a fortnight, occupying each afternoon; diseases of the throat, nose, and ear, occupying all day for three weeks; a course at the Central London Ophthalmic Hospital for four weeks, occupying each afternoon; and one in neurology at the National Hospital, Queen Square, lasting for two months. Full particulars and copies of all special course syllabuses may be obtained from the secretary, Fellowship of Medicine, 1, Wimpole Street, W.1., who will also supply information concerning the general course of work, which continues throughout the year.

IN connexion with the University of Liverpool Clinical School ante-natal clinics will be held at the Royal Infirmary on Monday and Thursday mornings at 10.30, and at the Maternity Hospital on each morning, except Saturdays and Sundays, at 11.30. The fee is £2 2s. for three months' attendance.

THE 300th anniversary of the birth of Marcello Malpighi, the founder of histology, was celebrated at Bologna on March 10th.

THE Lord Lieutenant of Berkshire, Mr. J. H. Benyon, will open the new operation theatres of the Royal Berkshire Hospital, Reading, on Tuesday next, May 1st, at 12.15 p.m.

THE Right Hon. W. Ormsby-Gore, M.P., Under Secretary of State for the Colonies, has been appointed a trustee of the Belt Memorial Fellowships for Medical Research in place of the late Sir Arthur Shipley.

A PRELIMINARY meeting of the Committee of Inquiry appointed by the Government to examine the questions raised by the use of tetra-ethyl lead in motor spirit was held on April 20th, when the existing information regarding lead ethyl petrol was considered and the question of procedure discussed. The next meeting of the committee will be held in Room 61, second floor, H.M. Office of Works, St. James's Park, S.W.1, at 11 a.m. on Monday, April 30th, and evidence will then be taken from the Air Ministry and the Anglo-American Oil Company. The proceedings will be open to the public. The duty of the committee is to ascertain whether the use of ethyl petrol is in any way dangerous to health, and any persons wishing to give evidence on this question should communicate with the secretary of the committee, Ministry of Health, Whitehall, S.W.1. The names of the members of the committee were given in the *Journal* of April 7th (p. 615) in a report of the discussion which took place in the House of Lords on March 29th, when Lord Gage announced its composition and described the scope of its investigations.

A TABLET has been erected in St. Mary's Church, Whitechurch, Oxon, in memory of the late Sir Rickman Godlee.

THE Treasury has made an Order under the Finance Act, 1926, exempting from key industry duty anhydrous hydrocyanic acid; lactic acid, which satisfies the requirements of the *British Pharmacopoeia*; metalehydo; methyl chloride; R. potassium chlorate; and syntbalin.

WITH the April issue of the *British Journal of Inebriety* a quarter of a century of publication is completed. The Society for the Study of Inebriety was founded in 1884, and the first number of its *Proceedings* appeared in July of that year. It was continued quarterly until the session 1901-2, when the proceedings were published in a single volume and the *British Journal of Inebriety* appeared for the first time. The present issue contains appreciative notes by Sir Arthur Newsholme, Sir William Wilcox, Mr. C. J. Bond, Sir William Collins, Dame Mary Sebarlieb, Mr. McAdam Eccles, and many others.

To mark the completion of its fortieth year the *Nursing Mirror and Midwives Journal*, which first appeared in 1888 as a supplement to the *Hospital*, publishes its current issue as a special "birthday number."

THE following appointments have recently been made in foreign faculties of medicine: Dr. A. Schmincke of Tübingen, professor of pathology at Heidelberg; Dr. Wilhelm von Gazen of Göttingen, professor of surgery at Rostock; Dr. Eduard Rehn of Düsseldorf, professor of surgery at Freiburg; Dr. Novoa Santos of Santiago, professor of medical pathology at Madrid.

THE International Labour Office has issued a further set of pamphlets forming part of a series which, when complete, will constitute the *Encyclopaedia of Industrial Health*. Eighty-seven parts have already appeared, and the seven now issued deal with the bakery trade; bleaching; breathing apparatus, respirators, and gas masks; cadmium, carbon bisulphide; carbon tetrachloride; cobalt. Each subject is dealt with in its relation to hygiene, pathology, and social welfare. The entire series will ultimately be published in volume form.

AN interesting account of the existing medical organization in Peking is embodied in a *Medical Guide* issued by the National Medical Association of China on the occasion of its seventh biennial conference there early this year. It is intended ultimately to expand the *Guide* into a complete medical directory for China. The present issue contains lists of medical institutions and of Chinese physicians; with descriptions of the public health organization and teaching institutions in Peking. In spite of the political and financial difficulties progress is being made in the provision of treatment and of educational facilities. There exists at least the framework of a public health service, and the Government maintains at Peking a National Epidemic Prevention Bureau, erected, perhaps with a subtle sense of humour, on a site adjacent to the Temple of Heaven. It appears that the hospitals and teaching institutions in the main are still largely dependent upon non-Chinese support; the Peking Central Hospital, which opened in 1918, is said to be the first general hospital established and conducted by Chinese practitioners on modern lines.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Medicero Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Racillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

### QUERIES AND ANSWERS.

#### OBESITY AFTER CHILDBIRTH.

"C. F." asks for suggestions for the treatment of a young married lady, aged 21, with a baby 10 months old, who has got very fat since the birth of her child, having increased about 21 lb. Her height is about 5 ft. 2 in. Dieting has been tried. There is no sign of hypothyroidism.

#### CREAKING IN THE JOINTS.

"H. S." asks: What is the significance of tendoney to creaking in the joints, without other signs or symptoms, developing at the age of 30? What is the significance when this is associated with slight thickening of synovial edge of joints, with some aching and tiredness in all joints (chiefly large) after movement?

#### DERMATITIS AFTER ULTRA-VIOLET RADIATION.

"W. A. K." asks for suggestions for the treatment of a mild dermatitis of the face—especially nose—in a lady, aged 25. The condition followed a course of ultra-violet radiation nine months ago. Being in an overheated room causes conspicuous and unsightly red areas to appear. Sodative lotions, ointments, and hazeline preparations have failed to effect any improvement.

#### INCOME TAX.

"A. S. B." has been building up a practice *de novo* and asks for information on various points, the nature of which will be seen from the replies.

\* \* (1) The return for 1928-29 should be made on the amount of the gross income of 1927-28, less the expenses incurred in that year. (2) The amount to be claimed for the accommodation, surgery, and use of waiting room provided by his parents is the amount reasonably paid; if no payment was made no deduction is due. (3) The same applies to the services given in keeping the rooms in order, etc. (4) Books are like instruments, in that only replacements are allowed. (5) The subscriptions stated seem to us to be allowable.

#### Salary with House, etc.

"C. L. P." holds a resident hospital appointment with salary, plus house, rates, fuel, and light.

\* \* He is taxable on the salary only, but should bear in mind that the position as regards income tax would be otherwise if his appointment were for a fixed amount, subject to deductions for house, etc., though the total advantages of his appointment might be the same.

#### Motor Car Transaction.

"C. R. D." bought a 15.1-h.p. car in February, 1923, for £863, and sold it in March, 1928, for £125, when he bought an 11.8-h.p. car for £650. What can he claim?

\* \* (1) As a claim to obsolescence allowance the amount is £650-£125=£525. We assume that the occasional private use is negligible; if it is not, some deduction should be made on that account. (2) Depreciation allowance due is 15 per cent. on £650 for the year 1928-29. "C. R. D." does not state the date to which he makes up his year's accounts; the obsolescence allowance has to be treated as one of the year's expenses, and if his accounts are made up to December 31st it will not affect his liability until 1929-30, but if he has been taking March 31st or April 5th as the closing date, then the financial year affected will be 1928-29.

### LETTERS, NOTES, ETC.

#### FIVE GENERATIONS ATTENDED BY ONE DOCTOR.

IN our last issue (p. 700) Dr. J. J. Hood asked whether any other medical practitioner had had the experience of attending five generations in one family. Mr. E. B. TURNER (London) writes: I have attended five generations in two families, and in one of them the fifth individual (a girl) is now about 14½ years old, so that (with luck) I might even run to a sixth!

COLONEL A. N. FLEMING, A.M.S. (ret.) (Edinburgh), writes: I can quote the case of the late Dr. Gibson of Campbelltown, Argyllshire. About forty years ago my great-grandmother died and before her death my sister had two children. Dr. Gibson had been the family doctor for many years, and at some time or another attended all the individuals concerned. Dr. Gibson had another claim to fame: not only did he live to be nearly 100 years of age, but actually continued in active practice till he was well over 90.

#### THE FORGOTTEN SWAB.

DR. N. J. LETTERS (Sydney) writes: The second of the cases recorded in Dr. Segar's interesting memorandum on swabs left within the abdomen (January 21st, 1928, p. 95) is not absolutely unique. In Willard Bartlett's *After Treatment of Surgical Patients* (C. V. Mosby Company, St. Louis, 1920), vol. 1, p. 179, I find the following: "A colleague requested me to explore one of his patients for a very ill-defined symptom-complex, which had followed an operation on the pelvic viscera. We were both surprised, and my colleague greatly embarrassed, by finding a very large gauze pad tightly encapsulated between intestinal coils. The interesting thing about this case, and the reason for quoting it, is that it exemplifies in no uncertain way Nature's method of spontaneous relief, which must be rather frequently afforded such patients. There was no mistaking the fact that one corner of the thick gauze pad was drawn out and twisted into a conical mass, of which the distal six or eight centimetres were smeared with faeces. Upon further inspection of the wound we found that this gauze cone had been withdrawn from an opening in the intestine, into the lumen of . . . was gradually being drawn by peristalsis . . . in the course of time, the newly formed . . . lay would have been emptied and its walls collapsed; then, had the foreign body not obstructed the intestine, it would have eventually been passed out through the anus, and quite possibly never been noted at all by the patient."

#### BACK TO SIR THOMAS BROWNE.

"N. 3" writes: I see that the old dispute about the inheritance of acquired characteristics has been raised once again, though not with asperity, in your columns. On this matter some of us are willing, with Omar, to leave the Wise to wrangle. But when such questions crop up I am reminded of the sayings of a physician of long ago. Sir Thomas Browne was well aware of the "sturdy doubts and boisterous objections, wherewith the unphilosophy of our knowledge too noisily acquainteth us." "I remember (he says) a Doctor in Physick of Italy, who could not perfectly believe the immortality of the soul, because Galen seemed to make a doubt thereof. . . . The whole Creation is a mystery, and particularly that of man. . . . In our study of Anatomy there is a mass of mysterious Philosophy." We may not be able in these times to follow the author of *Religio Medici* through all his curious speculations, but it is interesting to recall some of his musings on the problems of life. "The world," says Sir Thomas Browne, "was made to be inhabited by beasts, but studied and contented by man: 'tis the debt we owe unto God, and the homage we pay for not being beasts; without this the world is still as though it had not been." Nature he defines "not with the Schooles, the principle of motion and rest, but, that straight and regular line, that settled and constant course the wisdom of God hath ordained the notions of his creatures, according to their several kinds. . . . Now this course of Nature God seldom alters or perverts, but like an excellent Artist hath so contrived his worke, that with the selfe same instruments without a new creation hee may effect his ob-scurest designs." And again, introducing an odd train of thought, he makes this profound remark: "There is no liberty for causes to operate in a loose and straggling way, nor any effect whatever but hath its warrant from some universall or superiour cause." Elsewhere, in the *Garden of Cyrus*, he observes that "The Aequivoall production of things under undiscerned principles, makes a large part of generation, though they seem to hold a wide univocacy in their set and certain Originals. . . . All things began in order, so shall they end, and so shall they begin again." From a literary point of view these last two sentences are in striking contrast. I prefer the second.

#### SOUTH AFRICAN MEDICAL CONGRESS.

THE South African Medical Congress, limited should have been included in the list of the first annual scientific Association of South Africa (S.M.A.), and in our issue of April 21st (p. 684).

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 179.

# An Address ON INTRINSIC CANCER OF THE LARYNX, OPERATED ON BY LARYNGO-FISSURE: IMMEDIATE AND ULTIMATE RESULTS.\*

BY  
SIR ST. CLAIR THOMSON, M.D.,  
F.R.C.P., F.R.C.S.

## INTRODUCTION.

To be your guest of honour on this important occasion—the fiftieth anniversary of the foundation of the first and most important society in America devoted to the specialty—is a pleasure and a dignity I deeply esteem. In preparing a communication for this Association I have done my best to make it worthy of your acceptance by seeing that it was comprehensive and complete. It includes every case of intrinsic cancer I have treated by laryngo-fissure; the after-history has, fortunately, been available in every instance, and nothing has been extenuated or set down in malice prepense. This record is the result of over twenty-eight years' experience in carrying on the pioneer work of Butlin and Semon.† It embraces my earliest efforts as well as the results of more mature knowledge and technique. It therefore, I hope, carries the lessons both of early anxieties and of increased experience. It is the largest personal record which has, so far as I know, been contributed to the subject. Although none of us is quite free from bias, I venture to claim that the work is sincere.

## LARYNGO-FISSURE: A DEFINITION.

Laryngo-fissure is an inadequate expression to describe the operation I practise: Fissure of the larynx, or splitting the thyroid cartilage, or thyrotomy, should only be a term employed to indicate the route of approach. I also employ this route for a simple exploratory examination of the larynx. We may continue with the term "laryngo-fissure" in this sense; but students will start with mistaken ideas if they think that it still means simply "splitting the thyroid cartilage and taking out a vocal cord." The operation I practise means excising a mass which contains in its centre the whole cord, and includes the anterior commissure in front, part of the arytenoid behind, the ventricular band above, and the subglottic area below. This excision goes deeply enough to include the perichondrium lining the thyroid cartilage and, occasionally, that on the inner side of the cricoid ring. As the greater part of one thyroid ala is also excised (to obtain freer access and secure better healing) it will be seen that a so-called "fissure" really means a partial laryngectomy. Operations for malignant disease should be designed to meet variable conditions, the main object being to obtain a full-face view of the whole extent of the disease so as to remove it, with a satisfactory margin of healthy tissue in all directions, while securing the safety of the patient and avoiding unnecessary mutilation.

## CLINICAL MATERIAL.

I have operated, through a laryngo-fissure, on 70 cases of intrinsic cancer of the larynx.

TABLE I.—Cases Operated upon by Laryngo-fissure (1900-1923).

	No. of Cases.	Private Cases.	Hospital Cases.	Age Limits.
Male ... ..	63	56	7	40-80
Female ... ..	7	4	3	35-58
Total ... ..	70	60	10	

## Proportion of Male and Female Cases.

Looking at Table I we notice the large preponderance of males and of cases in private practice. Hospital patients

\* Read, by invitation, before the American Laryngological Association at its semi-centennial meeting in Washington on May 1st, 1923.  
† For the cases recognized early and promptly operated upon by those best qualified to do so, the methods taught by Mr. Butlin have yielded results which may well be ranked among the chief triumphs of modern surgery" (D. Bryson Delavan, American Laryngological Association 26th Meeting, 1904, p. 167).

are only less numerous for the simple reason that the ignorant and uneducated do not present themselves early for what they regard as a trifling huskiness, or, if they do, will not accept advice until the lesion has so far advanced that complete laryngectomy is the only possibility.

## Age Distribution.

In the next table (II) we note the incidence of my 70 cases according to sex and decade.

TABLE II.—Incidence, according to Age and Sex, of 70 Cases of Intrinsic Cancer of the Larynx.

Ages:	21-30.	31-40.	41-50.	51-60.	61-70.	Over 70.	Over 80.
Male ... ..	0	2	14	28	13	5	1
Female ... ..	0	3	2	2	0	0	0
Total (both sexes)	0	5	16	30	13	5	1

Here it is noticed that cancer of the larynx is not unknown between 30 and 40 years of age (of course, cases at much earlier ages have been recorded); that, in men, it may occur in advanced life; and that it appears to be most frequent with them in the sixth decade of life. With regard to the females in my list (7) the numbers are, perhaps, too small to justify many conclusions; but it is at least noteworthy that, with them, cancer would appear to be met with earlier in life and to be rarer after 60. All these women were non-smokers and abstainers.

## Early Experiences.

All these 70 cases were operated on through a laryngo-fissure. The first case was twenty-eight years ago, in 1900, when I followed the technique I had learned at first hand from Butlin and Semon. It included the injection of morphine, the insertion of Hahn's tube, the curcetting of the wound after piecemeal removal of visible disease, the abandonment of the tracheotomy tube at the conclusion of the operation, and the return of the patient to bed "with the head on a low pillow." As always happens when looking back on the road of surgical progress, one wonders at so many successes.

## RESULTS.

### Alive and Free from Disease.

My results are displayed in the following tables. The first shows that, of 34 patients alive to-day, 32 have survived periods varying from three to nineteen years from the date of operation.

TABLE III.—Thirty-four Cases of Intrinsic Cancer of the Larynx Alive and Well, Without Recurrence, after Laryngo-fissure.

Case No.	Age at Operation.	Sex.	Present Age.	Period since Laryngo-fissure.	Case No.	Age at Operation.	Sex.	Present Age.	Period since Laryngo-fissure.
6	59	M.	78	19 years.	45	35	F.	42	7½ years.
11	48½	M.	64½	16 "	47	60	M.	67	7 "
18	65	M.	78	13½ "	50	53	M.	53½	4½ "
21	66½	M.	80	12½ "	52	40	M.	45	6 "
22	59	M.	72	12½ years; 11 since second operation.	53	58	M.	64	6 "
26	46	F.	57½	11½ years since first cord; 4½ since second cord.	54	58	M.	64	5½ "
27	57½	M.	69	11½ years.	55	47	M.	55	5½ "
29	47½	M.	59	11½ "	56	80	M.	83½	5½ "
31	50	M.	61	11 "	58	79	M.	81	5 "
32	53	M.	64	11 "	59	52	M.	57	5 "
33	67	M.	78	11 "	61	45½	F.	55	4½ "
35	60	M.	70	10 "	62	58	M.	61	2½ "
38	49	F.	50	9½ "	63	55	M.	55½	3½ "
41	33	F.	41½	8½ years since laryngo-fissure; 7½ years since partial laryngectomy.	64	74	M.	77	2½ "
42	48	M.	55½	8½ years	65	54	M.	57	3 "
44	58	M.	66	8½ "	66	62	M.	65	3 "
					69	55	M.	56	4 months.
					70	62	M.	62	2 "

Two cases are too recent to support any claim for prolonged cure, but their inclusion serves to illustrate other points.

#### Female Cases.

In this table the vitality of the females may be noted. Five out of seven are alive at periods varying from four and a half to eleven and a half years afterwards, although two of them have had to be treated for a recurrence. In Table IV it will be seen that the two other females in my collection (Nos. 12 and 35) survived fourteen and a half and nearly four years, to die, without any recurrence, of influenza and cerebral haemorrhage.

#### Healthy, Useful, and Prolonged After-History.

Attention might be directed to the advanced age of many of the survivors, to their health and vigour, and to the social well-being secured by having conserved a useful voice. No. 11 is a Canadian, sent to me sixteen years ago by Dr. Birkett, whose diagnosis was confirmed by you, Mr. President, clinically, and by Dr. Jonathan Wright from the biopsy. No. 18 is an active shipbuilder in Scotland. No. 21, in his eightieth year, writes that he still cycles. No. 31 is an admiral; he is devoted to social work and can address meetings in the open air. Four are physicians in active practice (Nos. 52, 59, 63, and 66). Two are lawyers who conduct large affairs (Nos. 47 and 55). A clergyman is able to preach twice on Sunday (No. 44). A schoolmaster retains his post (No. 50). A gentleman, aged 67 when operated on, is now 78 (No. 33). Three years ago he passed safely through the operation for enlarged prostate. This year he celebrated his golden wedding and made a speech which was audible at a dinner he gave to 120 of his employees. No. 56 is a retired judge who follows the hounds on horseback, five and a half years after his operation and in his eighty-sixth year.

#### Deaths from Other Causes.

Of the 73 patients 18 have died from other causes, without recurrence (Table IV). Of these, it will be noticed that 13 had lived a minimum period of three years with-

TABLE IV.—Eighteen Deaths from Other Causes, Without Recurrence.

Case No.	Age at Operation.	Age at Death.	Period after Operation.	Cause of Death when Ascertainable.
2	49	50½	1½ years	Laryngitis.
3	48	58	10 "	Tubercle.
5	54	61	7 "	Unknown (hospital patient, inspected 2 years before death and found sound).
8	58	61½	3½ "	Aneurysm.
9	68	74	6 "	Bronchitis.
10	55	60-2 63	5-7 8 "	Pneumonia (an Indian subject).
12	53 (F.)	67½	14½ "	Influenza.
17	69	75	5½ "	Cerebral haemorrhage.
23	68	76½	8½ "	Urinary toxæmia.
25	72	84	12 "	Heart failure.
28	48	49	11 months	Developed pleuro-pneumonia with fetid empyema 1 month later. Operation: good recovery.*
30	63	65	1½ years	Angina pectoris.
34	75	85½	10½ "	Heart failure.
35	58½ (F.)	62	3½ "	Cerebral haemorrhage.
36A	70	74	4 "	Unknown.
37	69½	78	9 "	Heart failure; arterio-sclerosis.
40	56	55	50 hours	Operative (haemorrhage, morphia, pneumonia).
51	42	42	4 days	Operative (rupture of oesophagus).

\* No details obtainable, but Logan Turner found no signs of recurrence two months before death.

out any recurrence, while 3 of them died ten or more years after operation. (The two "operative deaths" will be considered later.)

\* Shown before the Royal Society of Medicine, November 4th, 1927. See *Proc. Roy. Soc. Med.*, December, 1927, *Laryng. Sec.*, p. 1.

#### Deaths from Malignant Disease Elsewhere, Without Recurrence.

If time permitted it would be interesting to study in detail the seven cases in the next table—that of death from carcinoma elsewhere, without local return of the disease (Table V). In two of them (Nos. 15 and 57) the virulence of the cancer must have been very intense for glands in the neck were invaded within four and six months, and the patients were dead within seven and eleven months, although the larynx in each case was free from recurrence.

In contrast to these cases are Nos. 39 and 7, in which the glands did not develop until four and seven years after operation.

In Case 1 (the first I ever operated on) I watched the larynx remaining free, while a cancerous growth developed on the lingual tonsil on the opposite side.

Case 13 shows how a patient can remain free of disease, in excellent voice and vigour, for eleven years and then die of malignant disease so remote from the larynx as the gall-bladder and liver.

TABLE V.—Seven Deaths from Later Development of Malignant Disease Elsewhere, the Larynx Remaining Free.

Case No.	Age at Operation.	Time of Onset after Operation.	Age at Death.	Time Elapsed since Operation till Death.
1	47	Malignant disease at base of tongue opposite side, started 1½ years after operation. Larynx filled up 3 to 7 months after operation. Laryngectomy after 9 months, but no cancer growth found in excised larynx (7 syphilis).	50	3 years.
7	43	Diffuse malignant disease in glands of neck 7 years later.	51	7½ years.
13	58	Death from malignant disease in abdomen, found at operation too extensive for removal.	69	11 years.
15	52	Infiltration of glands of neck within 4 months.	52½	7 months.
39	64	Glands in neck.	68½	4½ years.
43	54	Mediastinal glands (x-ray findings).	57	3 years.
57	39	Glands in neck within 6 months.	39½	11 months.

#### Deaths from Local Recurrence.

We now come to the local recurrences. There were only 11, all males. It will be noticed in Table VI that in 8 of these the recurrence took place within the first year. This supports Semon's dictum that a recurrence generally takes place within the first twelve months. Personally I feel little anxiety if the third month passes without any suspicious symptoms.

TABLE VI.—Eleven Deaths from Local Recurrence.

Case No.	Onset after Fissure.	Period till Death after Fissure.
4	8 months	20 months and 12 months after total laryngectomy.
11A	7 4 to 6 months	29 months.
14	3 years	3 years (second laryngo-fissure; death from idiosyncrasy to heroin).
16	2 months	5 months.
19	3 years	4½ years.
20	3 months	1 year.
24	1 month suspicion, and certain in 4 months; tracheotomy at end of 5 months	15 months.
46	2 months (declined laryngectomy)	11 months.
48	2½ years	4½ years.
49	2 months	7 months.
67	2 months	4 months.

These early relapses should not be regarded as a "recurrence of disease." We are more likely to advance the subject if we frankly regard them rather as "incomplete removals," and then investigate why the operation was a failure, or why the case was unsuitable for this type of operation.

The other three re-growths developed three years after the laryngo-fissure. Case 14 was in a very alcoholic subject. The lesion occupied the anterior two-thirds of the right

cord, invaded the commissure, and descended into the subglottic space. Here I was a little doubtful of having secured sufficient margin, and the pathologist was unable to report a good circumference of healthy tissue. The patient returned to India (and to his alcohol and tobacco), was there inspected and passed from time to time, and returned exactly three years afterwards with a recurrence at the anterior extremity of both cords and in the subglottic space below the anterior commissure. At the second laryngofissure it was seen that the re-growth had originated in this area. His death from heroin (recorded under "operative deaths") was particularly disappointing, as the pathologist's report encouraged the hope that the second removal had been complete.

No. 19 was a case of long-standing hoarseness, in which a large growth was almost entirely located in the subglottic region, and required the exposure of the inner surface of the cricoid. The pathologist reported on the removed mass that "the growth has reached to the line of excision at two margins." Yet three clear and active years passed before there was any suspicion of re-growth. This occurred so stealthily in the subglottic area that, when it declared itself, the disease was too advanced for further operation.

No. 48 was a similar case, but more promising. The disease left each extremity of the cord free, but descended on the inner surface to below the level of the cord. Excision, to eye and touch, appeared to be satisfactory, but the pathologist reported "there cannot be much margin of safety posteriorly." The patient was regularly inspected, and remained quite free for three years, when the disease returned on the same side. Laryngectomy was recommended, but declined; he had radium treatment elsewhere, and died one and a half years after the return had been diagnosed. He, like Case 14, indulged freely in whisky and tobacco, both before and after laryngofissure.

In all these three cases it was the subglottic situation which thwarted success.

#### Operative Deaths.

Of the 74 laryngo-fissures performed on 70 patients (2 of the 70 having been operated on for a local recurrence and 2 requiring a supplementary laryngo-fissure) 2 have died within forty-eight hours of the operation. The first case, No. 14, has already been referred to in Table VI. He was successfully operated on in 1913. After three years' absence in India he returned with a local recurrence; a second laryngo-fissure passed off without untoward incident in 1916, but he died forty-eight hours later with drowsiness, contracted pupils, and complete suppression of urine. There was no unusual bleeding at the operation, but a small haemorrhage took place twenty-four hours after. During my absence he was given half a grain of heroin, in three doses of one-sixth of a grain, within twenty-four hours. One of these doses had not been ordered; yet half a grain was not a large dose. A tracheotomy tube had, fortunately, been left in after operation. Death appeared to be due to an idiosyncrasy for heroin in a very alcoholic subject.

The second case, No. 40, had suffered from syphilis of the larynx for four years before a subglottic intrinsic cancer developed. There was much bleeding at the operation and again within two hours. Through a misunderstanding more morphine was given than was intended—namely, three-quarters of a grain—and he died with symptoms of septic pneumonia within forty-eight hours of operation. A tracheotomy tube had been left *in situ*, on account of the free bleeding at the operation, the subglottic extension of the disease, and the syphilitic basis.

A third case, No. 51, died on the fourth day from rupture of the oesophagus, due to post-anaesthetic vomiting.

The last was a very rare accident, not connected directly with the operation. The other two occurred in very unpromising subjects, one being certainly syphilitic and both of them alcoholic. Still, I think death would have been avoided if no soporific had been given. I now refuse to give an opiate of any kind before or after operation, and I forbid all "dopes" before anaesthesia (mixed, local and general). Accepting these 3 cases as operative deaths, this would give a death rate of 4 per cent.—a very

different figure from that recorded by the pioneers of this subject, and from that still existing in the few statistics which are rarely published.

If permitted to delete case No. 51 (rupture of the oesophagus) I have had no operative death since case No. 40. This sequence of 30 cases without a disaster encourages me to give it as my opinion that if a laryngo-fissure is carried out with the precautions and care I insist on, in regard to haemorrhage and the descent of blood into the bronchi, then it should be an operation free from any danger, except those incidental to all operations.

#### Lasting Cure.

We need not revive barren discussions as to how long after operation a patient may be regarded as permanently cured of cancer.

With few exceptions, all patients are in middle or advanced life. To ensure a comfortable and a vocal existence for ten to twenty years to 12 men who have passed their forty-seventh to sixty-seventh year (as in the first 12 cases of Table III); to operate on men of 79 and 80 years of age (Nos. 58 and 56), and to show them healthy and vigorous five years afterwards; and to restore doctors, lawyers, clergymen, and schoolmasters to their calling, are surely sufficient evidence to claim this method as securing permanent cures.

You, Mr. President, when addressing this Association on this same subject twenty-four years ago, said that "statistics based on alleged cures of less than three years' duration are worthless."

A scrutiny of the tables I have submitted will show that 63 patients are eligible on this basis, and that 48 of them were alive and well, and free from recurrence at the end of three years.† This lasting cure of 76 per cent. has been obtained without restricting oneself to particularly promising cases. As the indications for laryngo-fissure have not yet been quite established—beyond that of being a suitable operation for many cases of intrinsic cancer—I thought it right to try it in various intralaryngeal manifestations of the disease. Although this may have impaired the statistical results, it has enabled me to form some clear conclusions as to the indications and limitations of the laryngo-fissure route for the eradication of intrinsic cancer of the larynx. These will be embodied in a forthcoming publication.

#### CONCLUSIONS.

I trust that the evidence I have submitted justifies the conclusions I have now formulated for some years. This latest and largest record satisfies me that if intrinsic cancer of the larynx is diagnosed early it is best operated on by laryngo-fissure—an operation which should be free from danger to life and followed by an adequate voice and a lasting cure. The only necessities for this consummation are early diagnosis and meticulous care in operative precaution and procedure.‡ By educating the public to pay prompt regard to persistent hoarseness, and by teaching the profession to appreciate the niceties and necessities of early diagnosis, the number of laryngo-fissures and the proportion of lasting cures will steadily increase, while the need for laryngectomy will as progressively diminish.

In other regions of the body there may be better remedies than surgery can supply. In intrinsic cancer of the larynx other, simpler and surer, remedies no doubt will one day be discovered; but, at present, there is no better way than surgery and the laryngo-fissure route. By this we can secure results which have not been surpassed in the treatment of cancer in any other internal region of the body.

#### REFERENCE.

1 D. Bryson Delavan: *Trans. Amer. Laryng. Assoc.*, 26, 1904, p. 155.

\* "The results of indiscriminate operation have been so bad that their records are unobtainable because suppressed" (D. Bryson Delavan, loc. cit.).

† These figures are arrived at by deducting from my 70 cases the 2 recent cases (69 and 70), the 3 who died of other diseases before the three years were completed (2, 28, and 30), and the 2 operative deaths (40 and 51). This leaves 63 cases on which to formulate results. On the other side of the balance sheet are the 32 three-year survivors in Table I; the 13 who died of other diseases after a lapse of three years (Table IV); and the 3 cases which succumbed to malignant disease in other parts of the body, four and a quarter, seven and a half, and eleven years after laryngo-fissure (Table V). These, added together, show 43 who had passed the three-year limit.

‡ Mistakes hardly short of criminal have occurred in laryngeal operations done by inexperienced men working with absolutely no trained helpers (D. Bryson Delavan, loc. cit.).

## ANASTOMOSES BETWEEN THE RECURRENT LARYNGEAL AND PHRENIC NERVES.

*The Condition of the Intrinsic Muscles and Nerves of the Larynx of a Rhesus Monkey more than Three Years, and Two Years, after Operation.*

BY

LIONEL COLLEDGE, M.B., B.Ch.CAM., F.R.C.S.,  
SURGEON, EAR AND THROAT DEPARTMENT, ST. GEORGE'S  
HOSPITAL;  
AND

SIR CHARLES BALLANCE, K.C.M.G., M.S., F.R.C.S.,  
CONSULTING SURGEON, ST. THOMAS'S HOSPITAL.

(With Special Plate.)

### *The Operations.*

**Right Side.**—Recurrent laryngeal-phrenic end-to-side anastomosis performed three years and four months before death. A longitudinal incision was made in the middle of the phrenic nerve; the divided distal end of the recurrent laryngeal nerve was inveigled into the slit in the phrenic nerve and fixed by one stitch of the finest catgut. On direct examination of the larynx the right vocal cord was seen to be paralysed.

FIG. 1.—Rhesus monkey. Recurrent laryngeal-phrenic anastomosis end-to-side. (Small median incision made in middle of phrenic trunk.)

FIG. 2.—Rhesus monkey. Recurrent laryngeal-phrenic end-to-end anastomosis. No anastomosis of distal part of phrenic to any other nerve.

**Left Side.**—Recurrent laryngeal-phrenic end-to-end anastomosis performed two years before death. The cut ends of the two nerves were brought together by one stitch of the finest silk (Van Horn, arterial). On direct examination of the larynx the left cord was seen to be paralysed, while the right cord was moving normally. The distal end of the divided phrenic nerve was not anastomosed to any other nerve.

### *Result of the Experimental Operations.*

(A) **The Vocal Cords.**—Six months after the operation on the right side the right vocal cord was moving synchronously with the left. Six months after the operation on the left side the left vocal cord showed a wider abduction movement than the right. It must be remembered that on the left side the recurrent laryngeal nerve had been attached to the whole phrenic nerve. Thus while the excursion of the right cord, following end-to-side anastomosis, was approximately normal, the excursion of the left cord following end-to-end anastomosis was greater than normal. One week before the death of the monkey Sir David Ferrier, Professor Cushing, and Dr. Dalo saw the movements of these vocal cords through the direct laryngoscope, and the greater movement of the left vocal cord was still evident. The movement of the vocal cords was filmed,<sup>1</sup> and the wider abduction excursion of the left cord was demonstrated in the film.

(B) **The Diaphragm.**—It was obvious on inspection of the abdominal wall that the right half of the diaphragm was contracting while the left half was paralysed. Professor Elliot Smith, Dr. Beattie, and Mr. Melville examined the movements of the diaphragm by means of the radiographic screen.<sup>2</sup> Their report states that all parts of the right half of the diaphragm were contracting equally and

well, and that there is no contraction of any part of the left half of the diaphragm, the cupola moving upwards and downwards with respiration. After the left half of the diaphragm was paralysed it was noticed that the monkey never regained the power of moving and jumping rapidly about the large cage in which he was confined. At no time did this monkey suffer either from stridor and difficulty in breathing, or from paradoxical movement of the vocal cords.

### *Necropsy.*

(A) **The Diaphragm.**—The right half of the muscle of the diaphragm was thick, firm in texture, red in colour, and of normal appearance. The left half of the muscle of the diaphragm was thin, light pink in colour, and flabby in texture. Joining the left phrenic nerve in the thorax (below the site of section) was a small nerve which arose from the brachial plexus. This root of the left phrenic nerve was not seen at the operation. The left phrenic nerve below the site of division was smaller than the right phrenic nerve.

### DESCRIPTION OF PHOTOMICROGRAPHS ON PLATE.

**Note.**—The right recurrent laryngeal nerve was divided and the distal end anastomosed with the phrenic nerve three years and four months before the death of the monkey. The left recurrent laryngeal nerve was divided and the distal end anastomosed with the phrenic nerve two years before the death of the monkey.

FIG. 1.—Left crico-arytenoides posterior muscle ( $\times 850$ ). Note the transverse striation of the muscle. Cajal stain.

FIG. 2.—Right crico-arytenoides posterior muscle ( $\times 850$ ). Note the transverse striation of the muscle. Cajal stain.

FIG. 3.—Left crico-arytenoides posterior muscle ( $\times 400$ ). Note the red organs and nerve fibres. Cajal stain.

FIG. 4.—Right crico-arytenoides posterior muscle ( $\times 350$ ). Note the perfection of the end organ on the side of the striated muscle fibre, also the nerve fibres. Cajal stain.

FIG. 5.—Left crico-arytenoides posterior muscle ( $\times 400$ ). Note regenerated bundles of nerve fibres in muscle. Cajal stain.

FIG. 6.—Right crico-arytenoides posterior muscle ( $\times 400$ ). Note regenerated bundles of nerve fibres in muscle. Cajal stain.

FIG. 7.—Left crico-arytenoides lateralis muscle ( $\times 850$ ). Note the transverse striation. Cajal stain.

FIG. 8.—Right crico-arytenoides lateralis muscle ( $\times 850$ ). Note the transverse striation. Cajal stain.

FIG. 9.—Left thyro-arytenoides muscle ( $\times 850$ ). Note the transverse striation. Cajal stain.

FIG. 10.—Right thyro-arytenoides muscle ( $\times 850$ ). Note the transverse striation. Cajal stain.

FIG. 11.—Arytenoides muscle ( $\times 850$ ). Note the transverse striation. Cajal stain.

FIG. 12.—Left recurrent laryngeal nerve ( $\times 850$ ). Note regeneration of axis cylinders. Cajal stain.

FIG. 13.—Right recurrent laryngeal nerve ( $\times 1,000$ ). Hardened in Muller's fluid and stained by the Weigert and Sirocco methods. Reticular appearances (neuro-keratin) in the medullary sheaths. The axis cylinders are coloured as well as the neuro-keratin network. "There is reason to believe that the apparent reticular structure is due to the way the myelene constituents have undergone coagulation and separation under the influence of the hardening reagent." The nerve has regenerated.

(B) **The Larynx.**—The intrinsic muscles on both sides were dissected and separately placed in hardening fluid. The small nerve going to each muscle was demonstrated, and as each muscle was defined a portion of the nerve was passing to it was divided. Thus each small muscle was placed in the hardening fluid with a portion of its nerve attached. Each of the muscles appeared to be plump, normal in appearance, and red in colour.

(C) **The recurrent laryngeal and phrenic nerves** were also preserved.

### *Remarks on Striated Muscle.*

On examining the microscopic sections of the intrinsic muscles of the larynx the pattern of the striation is seen to vary. It is hardly to be supposed that the striation of the different muscles is essentially different. The authorities agree that the microscopical appearances of muscle in contraction are not the same as when relaxation is present; indeed, Starling states that in contraction there is an apparent reversal of the situation of the light and dark stripes. According to Engelmann the isotropic (singly refracting) part diminishes in volume in contraction, while the anisotropic (doubly refracting) part increases. The real meaning of striation is unknown. This is not essential to contraction, for unstriated muscle contracts. The main difference between the two classes of muscle is that the

typical cross striated muscle fibre is dependent on the impulses from the central nervous system to set it into activity.

### The Stimulation of the Cortex Cerebri.

Before the monkey was killed the right cerebral cortex was stimulated with the faradic current, a Sherrington single electrode being employed for the purpose (see Fig. 16).

### DESCRIPTION OF PHOTOMICROGRAPHS ON PLATE.

Fig. 14.—Photomicrograph of muscle bundles in right half of diaphragm ( $\times 700$ ). Three years and four months after recurrent laryngeal-phrenic end-to-side nerve anastomosis: showing that this method of operation has left no permanent effect on this half of the diaphragm.

Fig. 15.—Photomicrograph of muscle bundles in left half of diaphragm ( $\times 350$ ). Two years after recurrent laryngeal-phrenic end-to-end nerve anastomosis. The distal end of the phrenic nerve was not anastomosed to any other nerve. No transverse striation is shown in the photograph. On examining many other sections faint striation of a muscle bundle was occasionally seen, and this perhaps was due to the fact revealed at the autopsy that below the point of resection of the phrenic nerve a small nerve from the brachial plexus joined the phrenic nerve in the thorax.

Fig. 16.—Drawing of right half of brain of the monkey (natural size). A, Faradic stimulation of the cortex at this point caused elevation of the upper lip on the left side. B, Stimulation of the cortex at B caused abduction of the vocal cords. Unfortunately the point of the cortex at which the maximal adduction movement of the vocal cords occurred was not marked. It was in front of the area which on stimulation caused abduction of the vocal cords. The adduction movement was much stronger than the abduction movement, which was distinct from the abduction movement associated with the respiratory rhythm.

The cortical areas stimulated correspond to those originally defined by Semon and Horsley. The interest of the cerebral stimulations carried out by us is that the nerve impulses passed along the phrenic nerve, then through the phrenic-recurrent laryngeal end-to-end anastomosis to the recurrent laryngeal nerve and intrinsic laryngeal muscles.

Semon and Horsley<sup>1</sup> showed that unilateral stimulation invariably produces bilateral effect. They at first thought that there was no abduction centre in the brain cortex, but they demonstrated that direct excitation of the accessory nucleus in the medulla always evoked abduction of the vocal cords. They found no difficulty in evoking complete bilateral adduction movement of the vocal cords by stimulating an appropriate area of the cerebral cortex. If the stimulation is prolonged the "besoin de respirer" overcomes the influence of the artificial stimulus and evokes a powerful abduction movement of the vocal cords. They explained these diverse effects in this way: Phonation (that is, adduction) is a purposive or volitional act, while abduction is essentially related to the so-called automatic processes of organic life—that is, abduction serves inspiration.

In the later paper these authors show that there is a definite area on the cortex of the brain, stimulation of which causes abduction of the vocal cords. They point out that Krause (1878) was the first to localize the phonatory area in the cortex of the dog's brain. Ferrier, however, had previously reported that excitation of a certain cortical area in the dog elicited barking. Risien Russell<sup>4</sup> described separate areas of the cortex of the brain in which excitation evoked the movements of abduction and adduction of the vocal cords. Risien Russell also separated the abductor from the adductor nerve bundles in the recurrent laryngeal nerve—the abductor fibres being situated on the inner side of the nerve, while the adduction fibres are on the outer side. Stimulation of the abductor fibres produced unilateral abduction movement only, while division of the abductor fibres caused atrophy of the corresponding abductor muscle. We have been unable to separate the abductor nerve bundle in the way described by Risien Russell.

### Operation in Man.

It would appear that the proper operation to perform in man in cases of paralysis of a vocal cord is recurrent laryngeal-phrenic nerve end-to-side anastomosis. This has been successful in the one case in which this operation has been carried out.<sup>5</sup> Independent of the cases in man in which by stab or gunshot wound, or during an operation, the recurrent laryngeal nerve has been divided, and in which an immediate anastomosis should be effected, we are of opinion that if a vocal cord (or cords) has been paral-

ysed for three months with no sign of improvement in the condition, a recurrent laryngeal-phrenic nerve anastomosis should be forthwith carried out.

*Note.*—Figures showing regeneration of the phrenic and recurrent laryngeal nerves after similar anastomoses had been effected were published in the *British Medical Journal*, March 26th, 1927 (see Figs. 5 and 6 in plate facing p. 555).

The experimental nerve anastomoses were carried out at the National Institute for Research, Mount Vernon, Hampstead. The microscopic specimens and photomicrographs were prepared by Miss Glascock and Mr. Stewart at the Royal College of Surgeons.

## OPERATION FOR PITUITARY TUMOUR.

### REPORT OF A CASE.

BY

ANDREW WATT, M.B., F.R.C.S., R. C. J. MEYER, M.D., F.R.C.S.,

AND

ANDREW CAMPBELL, M.B., F.R.C.S.,

GENERAL HOSPITAL, JOHANNESBURG.

(With Special Plate.)

A EUROPEAN, aged 23 years, complained that during the last five or six years his left eye had been noticeably weaker than the right. In November, 1926, he suffered from severe headaches when reading for an examination. In February, 1927, when marking the register, he found that when he thought the pen was touching the book it was actually about an inch away from it; he was unable to see with the left eye alone. There was no complaint of headache, no vertigo, and no vomiting. At the beginning of April Dr. Meyer was consulted, and the patient was sent into hospital for investigation under Dr. Andrew Watt.

The previous history showed that the patient had fallen off a horse in 1918; but though unconscious for some time he suffered no other ill effects. In 1919 he had influenza. In 1920 he was hit over the left eye by a cricket ball. There is no family history of nervous or eye trouble, and the father, mother, brothers, and sisters are all well. He smokes ten to fifteen cigarettes daily and is a total abstainer. His condition on admission to hospital was recorded as follows.

The patient is a well-built, healthy looking individual, about 5 ft. 8 in. tall. There is no abnormality in his gait and the grips of both hands are normal. There is no tremor; the motor functions and the various reflexes are normal, as is sensation. The bowels are regular and the appetite is good; there is no frequency of micturition, and urine analysis reveals nothing abnormal. The heart and lungs are sound, and the Wassermann reaction is negative.

Examination of the cranial nerves shows the sense of smell to be normal; vision is impaired, pupils react to light and accommodation, there is no ocular paresis, no nystagmus, and no strabismus. There is no anaesthesia of the face or scalp. The functions of the seventh nerve are normal, and there is no impairment of taste. The movements of the tongue and swallowing are normal. The basal metabolic rate is normal.

Blood sugar before glucose meal (200 grams)	0.11 per cent.
" " 30 minutes after glucose meal ...	0.16 "
" " 60 " " " " " " " " " "	0.14 "
" " 90 " " " " " " " " " "	0.13 "
" " 120 " " " " " " " " " "	0.14 "

Sugar was not found in the urine before the glucose meal, but a trace was present two hours after. The cerebro-spinal fluid was under a pressure of 250 mm. water. The globulin was not in excess of the normal, and the sugar percentage was 0.03. The sodium chloride figure was 720 mg. per 100 c.cm. No characteristic curve was obtained with gold solution. A cell count yielded a total of two lymphocytes per c.mm.

A blood count taken on June 18th was as follows: haemoglobin 95 per cent.; colour index 0.98; red cells 5,810,000; leucocytes 8,000; polymorphonuclears 52 per cent.; large mononuclears 2 per cent.; lymphocytes 46 per cent. The red cells showed slight anisocytosis with a very moderate degree of polychromasia.

The patient was referred to Dr. Campbell for examination of the ear, nose, and throat, and for the vestibular tests. Both drumheads were retracted, and he could hear a whisper at over 16 feet on both sides. Tuning-fork tests were normal. There was no spontaneous nystagmus, no spontaneous past-pointing, and

no inco-ordination; the body balance tests gave normal reactions, and diadokokinesia was present.

#### Vestibular Tests:

Turning to right gave an after nystagmus to left lasting 25 seconds.

Turning to left gave an after nystagmus to right lasting 35 seconds.

Turning to right past-points 6 inches to right with left arm.

Turning to right past-points 4 inches to right with right arm.

Turning to left past-points 10 inches to left with right arm.

Turning to left past-points 6 inches to left with left arm.

Cold syringing the left ear at 68° F. elicited a rotary nystagmus to the right in 45 seconds and past-pointing to left with both arms. Cold syringing the right ear at 68° F. elicited a rotary nystagmus to the left in 25 seconds and past-pointing to right with both arms. It was concluded that a supratentorial lesion was present.

#### OPERATION NOTES BY DR. CAMPBELL.

The diagnosis of a pituitary tumour was established and confirmed by beautiful stereoscopic films taken by Dr. Andrew Watt. The eye tests indicated pressure on the chiasma, perhaps more on the left than on the right side. This finding was corroborated by the vestibular tests. (For skiagram see Fig. A in special plate.)

On June 13th, 1927, under rectal anaesthesia, given by Dr. F. B. Mudd, a submucous resection of the nasal septum was performed in the usual way after removal of both middle turbinates and a slice of the right inferior turbinate which happened to be in the way. The nasal mucous membrane was sprayed with 1 ounce of 10 per cent. cocaine and adrenaline solution twenty minutes before operation. The anterior wall of the sphenoidal sinuses was thin and easily removed. The sphenoidal sinuses came into view, and a rounded tumour was found to occupy the upper part of the cavities. (See Fig. 1.) There was no septum between

FIG. 1.

the sinuses, but there were one or two spicules of bone which indicated its site.

A small piece of bone was removed from the most dependent part of the tumour by means of a gouge, and the rest of the tumour was uncapped with suitable forceps. There was little bleeding. The mucous membrane of the sphenoidal sinus was removed.

The result at this stage was that the tumour covered by dura was occupying the upper half, or almost half, of the sphenoidal sinuses. On removal of the very thin bone there was no dropping downwards of the tumour. A syringe introduced into the growth did not draw liquid, but gave the impression that the tumour was solid. No packing was introduced into the sphenoidal sinus. The only communication to the nose was through the sphenoidal ostia. The muco-periosteum covering the anterior wall of the sphenoidal sinuses had been reflected intact. A large piece of the nasal cartilage was slipped back between the septal flaps, and each side of the nose was packed with a glove finger into which gauze had been introduced, so as to keep the septal flaps lightly together. The operation lasted one and a half hours. After leaving the theatre there was some respiratory difficulty, and the patient did not come round for six hours.

On the following day there was a suspicion of an acute appendicitis, but this pain was probably due to the rectal ether. The nasal packing was removed in twenty-four hours. A mild antiseptic spray was used for another twenty-four hours, after which the nose was gently irrigated with saline solution thrice daily. The recovery from the first stage of the operation was uneventful. In a week he was up and walking about the ward. No improvement in eye symptoms followed at this stage.

On June 27th, under open ether anaesthesia and cocaine spray to the nasal mucous membrane, the operative field was reopened through the nasal septum. It was noticed that a large part of the cartilage which had been replaced had been absorbed. The sphenoidal sinuses were easily

entered. The tumour had not descended, and the whole sinus and dura were covered with granulations, which bled considerably. There was no difficulty in making a crucial incision of the dura, though the growth was probably also incised in the attempt. No descent of tumour was observed during the operation, and there was no suggestion that the growth was anything but solid. There was no escape of any liquid other than blood; bleeding after incision of the dura was easily controlled. The operative field was closed by bringing the septal flaps together without any packing in the sphenoidal sinus; fingers were again utilized to keep the flaps in apposition. Towards evening the patient was rational and appeared to be doing well. On the following day, though he had passed a good night, he did not seem quite rational. He was able to recognize the surgeon and nurses, but answered "Yes" to all questions and nothing else; by the evening he failed to recognize anyone. The temperature rose to 102° F., and we feared that meningeal symptoms were commencing, though there was no other indication of this.

On June 29th he woke up perfectly rational and rapidly improved, with a gradual drop in the temperature, which became normal on June 30th. After this he gave us no anxiety; he was allowed to get up a little on the eighth day after the second operation, by which time he was conscious of improvement in his eyesight. He was discharged from hospital on July 12th.

FIG. 2.—Visual fields, showing condition at dates before and after operation. Left vision—fingers at 2 metres; 25 mm. white. Right vision—6/5; 5 mm. white.

It was thought that a decompression by two stages was a safer procedure than by one operation. No thought of any attempt to remove the tumour was entertained. It is, however, possible that if the tumour descends and fills up the sphenoidal sinuses so that further decompression is not possible, then we may with greater safety remove the anterior muco-periosteal wall of the sphenoidal sinuses, leaving the posterior edge of the nasal septum *in situ*, and thus expose the tumour mass through windows which will remain permanently open. The tumour itself may then be attacked surgically or made to shrink by electro-coagulation.

The main danger of the trans-sphenoidal route is sepsis, laying bare the field of operation to invasion by organisms from a possibly septic nose or nasopharynx.

An attempt to remove the tumour at the first operation would probably, almost certainly, have resulted in infection of the intracranial structures and death; whereas by gradual stages, and as the occasion demands, this three-stage removal has much to recommend it from the point of view of safety. No attempt was made even to remove a small piece of tumour for the microscope because of the possibility of infection. No purpose would be served by an accurate knowledge of the pathology of the tumour. If it were found to be malignant nothing could be done, and if it proved to be innocent we could still do nothing more for the present. It is possible that in the descent of the tumour it may become strangulated by the narrow bony neck through which it must pass; this will not occur until the sphenoidal sinus is completely filled.

The fields taken by Dr. Meyer on October 4th, compared

with the fields before operation, show a considerable improvement in the patient's eyesight, especially in the right eye. There is a small perforation in the nasal septum, and there are a few adhesions between the septum and the lateral nasal wall. The anterior walls of the sphenoidal sinuses are easily inspected. There is no evidence of sepsis in the nose.

The patient was first seen in April, 1927, examined thoroughly and treated by surgical operation in June, and reported on after examination on October 4th.

#### NOTES BY DR. R. C. J. MEYER.

Objective examination showed no abnormality as regards the outward appearances, motility, and pupils; the Wernicke pupil reaction was demonstrated later. The fundus was healthy, but there was slight hypermetropic astigmatism; the subsequent wearing of glasses stopped all headaches. Right vision = 6/6, J.I. Left vision = hand reflex centrally, but fingers at 3 metres nasally. This called for examination of fields, the broad results of which are indicated in the diagrams. Fig. 3, A (right eye),

FIG. 3.

shows the right upper outer quadrant lost; the patient was quite unconscious of right quadrant loss of field until examination demonstrated it to him. In Fig. 3, B (left eye), the temporal hemianopia is seen to cross the vertical middle by about 15 degrees. The patient was quite conscious of loss of vision of left eye, which drove him to seek medical aid.

The examination suggested the presence of a pituitary tumour involving the left side much more than the right, but later on under portion of chiasma. I handed the case over to the physician, radiologist, and surgeon, but the patient could only come for observation (May 28th).

Two operations were performed—ono on June 13th and the other on June 27th. On July 13th, at the request of the surgeon, fields were again taken (there being no change in any other condition of the eyes). The right upper quadrant scotoma had now diminished to a smaller sector. (See Fig. 4, A.) The left scotoma had also diminished. (See Fig. 4, B.)

FIG. 4.

On September 1st a friend stated that the patient was "quite better," which meant, at any rate, a decided improvement. (N.B.—Patient lives in the country and over a hundred miles away.)

FIG. 5.

On October 4th the patient unexpectedly arrived for examination. This showed the right scotoma to be still further diminished. The left scotoma was also diminished somewhat. Right vision = 6/5, J.I. Patient does not feel the scotoma, and this does not exist for luminous objects at all now. Certainly a most striking improvement. (See Fig. 5, A.) The left disc shows great pallor of nasal side—that is, atrophy is showing actually at the disc. (See Fig. 5, B.)

## THE AFFINITIES BETWEEN RHEUMATISM AND TUBERCULOSIS.

BY

W. CAMAC WILKINSON, M.D., F.R.C.P.,

LONDON.

TUBERCULOSIS connotes the morbid changes caused by living tubercle bacilli in the living tissues of man and animals. As the tissues react they present lesions of endless variety in degree, kind, and time. The outstanding and characteristic lesion is the tubercle with its epithelioid and giant cells, but there are also lesions as acute as those of septicaemia or pyaemia, and, on the other hand, as chronic as those of chronic rheumatism. Indeed, it seems likely that many so-called "rheumatic" affections, which do not yield to antirheumatic treatment, are really manifestations of chronic tuberculosis. Even joint affections accompanied by pain and swelling may be tuberculous in nature.

The brilliant investigations of Liebermeister, with the help of his new acetic acid-antiformin method, seem to establish the frequency of chronic inflammation free from any tubercles as a distinct and even independent lesion of tuberculosis. These chronic inflammatory lesions are, indeed, often the end-results both of acute lesions and of true histological tubercle, but Liebermeister holds that they may be independent of either of these lesions and are common in many organs and parts. They have been overlooked because death does not occur in this chronic stage, and there is no chance of seeing them. Such lesions may be the *fons et origo* of the multifarious disturbances of function occurring in the early stages of chronic tuberculosis. The lesions are the most chronic that occur in tuberculosis, and cause mainly mild and transient symptoms. Thus it may be impossible after a long lapse of time to trace them to their true cause or fix the time of their occurrence. Living tubercle bacilli may be found in these chronic lesions, and evidence supports the view that these quiescent lesions may be reactivated. These lesions are most common in the secondary stage of chronic tuberculosis, when tubercle bacilli, in small numbers, more or less isolated, and certainly not in clumps or masses, are circulating in the blood, before tertiary disease occurs in the apex of the lung. Amongst other manifestations, tuberculosis may cause lesions suggesting rheumatism of joints with painful swellings, in some cases with erythema nodosum, in others with erythematous, pains also in muscles and in one or more joints; pains in the chest without signs of pleurisy, pains in the neck and in the eyes or head, disturbance of the heart's rate and rhythm—even pains in nerves (sciatica). Liebermeister has demonstrated the presence of these chronic inflammatory lesions notably in lymphatic glands, serous membranes, even in the meninges, in the lungs, liver, kidney, spleen, veins, skin, eyes, and larynx. May not these lesions be responsible for the various symptoms that may and do occur and pass away in the early stages of chronic tuberculosis, and especially of chronic apical tuberculosis?

For the most part these lesions elude us, and we can only bring them to light by means of tuberculin. Twenty years ago I suggested the possible existence of these lesions because doses of tuberculin excited pains in various organs and parts in a manner that seemed to indicate a focal reaction. For many years I have observed pains in special muscles and joints, time after time in the same part after each dose—in the hip, or knee, or little finger, or thumb, or heel; in the back or shoulder; in bones or muscles, such as severe cramps in the calves of the legs; pains also in the epigastrium, doubling up the patient after each dose, and even boring or lancinating or cutting pains in the shoulder radiating down the arm, or deep pain in the chest. There are strange individual idiosyncrasies, because in the same patient, after injections of tuberculin, the same parts are apt to suffer, though the site of injection varies. These pains, in fact, may be related to chronic inflammatory lesions and may be really focal reactions. One has great opportunities of studying these pains, their varieties and situations, after injections of tuberculin. Naturally there is no other way of investigating them.

Moreover, as a rule these chronic inflammatory lesions can only be investigated with the help of subcutaneous injections of tuberculin. But it does happen, fortunately, that these chronic inflammatory lesions of the early stage of tuberculosis may rarely disclose themselves beyond all doubt or cavil when they occur in structures visible to the naked eye, notably in the skin and structures of the eye and even in the larynx. The so-called pre-tuberculous laryngitis may be of this nature.

I know that my old teacher Radcliffe Crocker would not admit that there was any connexion between erythema nodosum and tuberculosis, while S. Mackenzie stated that erythema nodosum is frequently, if not generally, an expression of rheumatism. I may be skating on thin ice if I say that in my limited experience I have not once seen erythema nodosum apart from tuberculosis. All cases have reacted severely to tuberculin, and no case has had any relation to rheumatism. However, identity of lesion does not signify identity of cause. Histologically the lesions of erythema nodosum cannot be distinguished from rheumatic lesions of the skin, but Liebermeister has shown that such lesions may be caused by tubercle bacilli. At present I am bound to believe that erythema nodosum is a tuberculous lesion. Without tuberculin I could not have held any but the general opinion. I first pointed out the relation of erythema nodosum to tuberculosis in 1902, and since then all my evidence strengthens this view.

But, because its lesions are visible and cause unpleasant symptoms, the eye provides the best field for examining the remarkable affinities between chronic forms of tuberculosis and the so-called rheumatic affections which are attributed to chills or other indeterminate causes. For the last thirty years ophthalmologists have been at issue upon the "rheumatic" affections of the eye. The usual lesions in question are conjunctivitis, iritis, episcleritis, and scleritis.

In his great textbook (1926) Sir John Parsons writes that "rheumatism and gout are the chief causes of episcleritis and scleritis"; "most commonly there has been marked rheumatism." Later he says, "When tubercle is suspected injections of tuberculin may be employed." I say that tuberculin is the only means of settling the diagnosis. Unfortunately I have seen only three cases of episcleritis, because this uncommon disease does not come to a tuberculin dispensary, as tuberculosis is not suspected. In these cases tuberculin has not only established the diagnosis, but as the cardinal remedy, has rapidly brought about extraordinary improvement even in the course of a few weeks. All the pain, tenderness, and discomfort have abated, and photophobia has vanished. One of these cases had been diagnosed several years ago as "rheumatism of the head," and the two worst cases had been under treatment for years without any real improvement. Since tuberculin treatment has been adopted the eyes have assumed a normal appearance and the patients have no symptoms. But prolonged treatment will be necessary before it can be stated with any confidence that there will not be recurrence of the trouble.

Iritis is a common lesion in syphilis, and may arise from septic infection—sometimes secondary to carious and foul teeth—but tuberculosis may also cause iritis. Infection directly from the air is conceivable, but evidence points rather to infection by the blood current. Since removal of the eye has been advocated, it is very important to distinguish between a direct infection from the outside, when a lesion might be acute and progressive, and haematogenous infection, when the lesion would be chronic and circumscribed.

Again, early diagnosis requires the use of tuberculin, and since the lesion is generally chronic, tuberculin also offers the best hope of arresting the disease and preventing its recurrence. Sir John Parsons says that tuberculin "often fails to ameliorate the condition." I cannot presume to criticize such an authority without evidence, as I have not had an opportunity of treating a case of iritis, but reasoning from experiences in other cases I am inclined to think that failure such as this great authority has observed may be due not to the tuberculin, but to the administrator. Tuberculin treatment must be carried out by an expert with his own hands, and it must not be used merely to check

the disease temporarily, but to such a degree and in such doses that recurrence of the disease is prevented.

My chief experience has been with the common tuberculous lesion of the eye—"chronic conjunctivitis"—either as superficial ulcers or small granulomata and translucent cockscomb-like projecting masses. These conditions are often tuberculous; they occur in a tuberculous family; they all react to tuberculin, and, in my limited experience, always clear up under tuberculin in large doses—not less than 0.8 c.cm. or 1 c.cm. or more. But again success depends upon the skill of the operator, just as much as in the surgical treatment of glaucoma or cataract. Accordingly I am bound to hold the view that these eye lesions, like other lesions, belong to the secondary stage of tuberculosis. It is not enough to say "tuberculin may be used," because there is no other remedy that can consistently do so much real good.

These atypical lesions of tuberculous origin have a special interest. They have been called "rheumatic" because they do not conform to the histological or clinical picture of tuberculosis. There are no giant cells and no signs of caseation. They are mild, transient, and tend to recur. Both in the skin and eye they may pass away and never return, but without specific treatment, and even with it, recurrence at long or short intervals of time is common. They may be accompanied by swellings in joints and pains, and therefore may be designated "rheumatic." They are like the secondaries of syphilis which occur in the secondary stage and tend to heal. They bear this outstanding feature—that they occur only in mild forms of tuberculosis when slowly progressive or even occult lesions exist in the bronchial lymphatic structures. Thus they may be the obvious pacemakers for the common chronic disease—chronic phthisis—which subsequently fixes upon the apex of the lung. Tuberculosis may not be the exclusive cause of these chronic inflammatory states, but certainly the symptom-complex hitherto associated with "rheumatism" may be the effect of tuberculosis.

Thus certain diseases of the eye and skin, hitherto called "rheumatic," are really chronic forms of tuberculosis which, like serofula, lack entirely the character of a typical histological tubercle. Ophthalmologists have brilliantly illuminated this interesting chapter upon the affinities of rheumatism and tuberculosis; little wonder, seeing that these lesions in the eye in the secondary state of tuberculosis are essentially vascular and can be seen directly by the eye. Thus, after many years of controversy, ophthalmologists have furnished clinical, anatomical, and experimental proof that, at any rate in the eye, atypical lesions of a chronic inflammatory nature, without either giant cells or caseous changes, may be truly tuberculous.

If, then, these atypical bacilli, and can be seen, why may not similar mild tuberculous lesions occur in other vascular structures that are out of sight, and cause those disturbances of function which express themselves in an endless array of vague, various, and vagrant symptoms in so many organs and parts of the body during the secondary stage of tuberculosis? Thus the hitherto multifarious functional disturbances of the early stage of tuberculosis may possibly be traced to an anatomical lesion of delicate vessels caused by tubercle bacilli—few in numbers and perhaps attenuated in virulence. Like the lesions of serofula, of episcleritis, of chronic conjunctivitis, and even of erythema nodosum, there may be vascular tuberculides, mild and even transient, in many organs and regions of the body.

These widely scattered tuberculides do not obtrude themselves, and may escape detection. The more one uses tuberculin for purposes of diagnosis, the more one may become impressed with the idea that lesions may be responsible for these erratic symptoms of early and mild tuberculosis. When these mild and obscure symptoms occur in the early stage of tuberculosis, the use of tuberculin in diagnosis is safe and certain and has no rival. Such obscure symptoms and aberrant lesions may be easily overlooked or misinterpreted. But any serious student of tuberculosis, trained in the use of these scientific methods, may find tuberculosis in strange places and in unfamiliar forms. Special knowledge may enable him to "mark

down," accurately and precisely, these masked forms of tuberculosis in the eye, in the nose, in the larynx, and even in internal organs and systems, at a time when diagnosis is otherwise extremely difficult and treatment relatively easy. Certainly in such cases the effects of tuberculin used as a remedy by an expert are often magical in suddenness and completeness.

General hospitals, and some special hospitals, might help earnest students and suffering humanity by establishing a special ward and an out-patient department for the study of chronic tuberculosis in both its common and erratic forms.

## ENDOCRINE IMBALANCE AND ITS RELATION TO CHRONIC ARTHRITIS.\*

BY

G. L. KERR PRINGLE, M.C., M.D.Ed.,

HONORARY PHYSICIAN TO THE ROYAL BATH HOSPITAL, HARROGATE.

THE views and opinions of the ancient authorities before the days of cellular pathology and bacteriology are of distinct interest in the light of our present knowledge. Hippocrates laid down the axiom that "Gout never occurred in women until the menses had ceased." Trousseau<sup>1</sup> and Charcot<sup>2</sup> believed that chronic articular rheumatism was associated with the beginning and end of menstruation and with pregnancy. Orde,<sup>3</sup> in 1879, suggested that there was evidence to show that there was some relationship between uterine disorders and rheumatoid arthritis—such as severe arthritis with dysmenorrhoea and arthritic paroxysms coincident with menstruation—views with which I am in full accord.

At all these stages in a woman's life considerable strain is being thrown on the endocrine glands. These glands begin to assert themselves in early foetal life, and as they have no function in respect of external relation, their secretions must be entirely occupied with internal regulation, so that from the first any endocrine defect must disturb the balance. In childhood the endocrine system retards maturity to give time for further development, and utilizes glands such as the thyroid, subsequently katabolic in action, in the service of active growth. As puberty advances, the retarding gland—the thymus—atrophies, and the katabolic glands, like the thyroid, take on their own action. During pregnancy all the endocrine glands are working at full capacity, though some are antagonistic to each other. This continues during lactation, whilst at the climacteric the ovarian hormone disappears and more work is thrown on the thyroid, which itself is on the down grade.

There are two groups of endocrine glands:

1. Parasympathetic or extended vagus—anabolic in action—the cell-islets in the pancreas, and the parathyroids.

2. The sympathetic—katabolic in action—adrenals, thyroid, and pituitary.

The rhythm of life largely depends on the fluctuating balance between these two.

All the ductless glands, especially those co-operating with the sympathetic nervous system, participate in the development of sexual characters, the thyroid and possibly the post-pituitary tipping the balance towards femininity, the adrenal cortex and the anterior pituitary towards virilism. Thus the thyroid shows increased activity at puberty, the catamenia, marriage, and pregnancy, and undergoes partial involution at the climacteric.

There is a close association between the gonads and the pituitary: neither appears to be able to get on and develop without the help of the other. The internal secretion of the ovary stimulates the secretion of pituitrin, and the development of a corpus luteum in pregnancy checks this process on behalf of the foetus until the time for the uterus to contract and for the milk to flow.

Llewellyn<sup>4</sup> first drew attention to the association of the endocrines and chronic rheumatism, especially of the chronic villus type occurring in women at the menopause, expressing views which have been corroborated by Ribierre,<sup>5</sup> Rosen,<sup>6</sup> H. K. Thompson,<sup>7</sup> Cecil and Archer,<sup>8</sup>

and many others. At a discussion on climacteric arthritis<sup>9</sup> the subject was considered under the wider term of "hypoglandular arthritis." It was pointed out that this condition of joints was by no means confined to women at the climacteric, but that it was seen in young women due to thyro-pituitary failure. Cumberbatch concluded that there is a type of arthritis closely associated with, if not entirely due to, disturbance of the endocrine function of the ovary, and gave the following reasons for these conclusions.

1. Some of the cases occurred in young women in whom the menstrual function was being established. They developed arthritis of the rheumatoid type and amenorrhoea occurred. There was no evident primary focus of infection. The application of diathermy to the interior of the pelvis brought the arthritis to an end and menstruation returned.

2. Other cases occurred in women at the other end of menstrual life. In many the climacteric commenced at an early date and menstruation ceased. In these, again, there was no evident primary focus of infection. The application of diathermy usually arrested the arthritis and menstruation recommenced, in the cases in which the onset of the climacteric was premature.

Robinson considered that arthritis is directly or indirectly due to inactivity of the corpora lutea of the ovary. This inactivity may occur at any time after puberty, and may or may not be associated with absence of menstruation. Heating the ovary by diathermy increases the activity of the ovarian function.

Returning to the view of Trousseau and Charcot that chronic arthritis is a disease associated with the commencement and cessation of menstruation and also with pregnancy, I have seen quite a number of young girls in their teens in whom the start of menstruation had been delayed, or who had had one or two periods and then stopped. They were large, fat, well-developed girls, who complained of pains in joints and muscles.

One girl, aged 12½, had for six months complained of pain in her right knee; she was listless, had never menstruated, and had all the appearances of thyro-pituitary deficiency. X rays showed a small rarefied area just beneath the articular face of the cartilage of the tibia. Her tonsils were found to be septic, and removal was advised; this was carried out, and thyroid in small doses was also given. This case did not begin to improve until six months after the enucleation, when she started to menstruate, pain ceased, and she resumed her previous activity. Her mother suffered from chronic villus arthritis of the menopause.

In another case the patient's mother suffered from Raynaud's disease, which was not of a severe type. This girl was very much like the previous case in appearance; she was over-developed, was affected by amenorrhoea, and the rheumatic condition was more in the nature of a fibrositis of the creeter muscles of the spine, though there was some doubt as to the condition of the dorsal vertebrae as seen with x rays. When I first saw this patient she had had her tonsils enucleated about fourteen days previously and was in a markedly hyperthyroidic state, with rapid pulse, muscular tremor, and thyroid gland slightly enlarged.

Crammer<sup>10</sup> remarks that "it is well known that acute infections are sometimes followed by symptoms which may not unreasonably be attributed to disturbances of the thyroid-adrenal function. The stimulation produced by these toxins may develop into a Graves's disease." The thyroid is one of the defensive agents against infection, and I believe in this case the removal of the septic tonsils produced a flooding with thyroxine, the patient having most probably been hypothyroidic before.

Langdon Brown<sup>11</sup> points out how frequently tonsillar sepsis may be a factor in producing hypothyroidism in childhood. We are familiar with the fact that tonsillar sepsis is likely to excite hyperthyroidism after puberty, but until the gland has experienced the activating effect of puberty—that is, before the gland has taken on its katabolic duties—it is apparently more easily exhausted than excited to over-activity. Once the thyroid has taken on its katabolic duties we find patients with all the symptoms of rheumatoid or atrophic arthritis—as, for instance, the young woman in the early twenties.

Llewellyn had frequently pointed out that the early symptoms of rheumatoid disease, prior to the development of joint swellings, are very similar to the secondary features of Graves's disease and also Raynaud's disease, and he believes that all these diseases are due to endocrine instability or imbalance. McCarrison had pointed out that, in the goitrous regions of the Himalayas rheumatoid arthritis is very common.

\* Abstract of a paper read before the Harrogate Medical Society, February 17th, 1928.

In my experience also I believe that a history of thyroid enlargement and rheumatoid arthritis is extraordinarily common. When you examine the patient there may be no evidence, but on inquiry into the past history it is astonishing how often you will get a history of goitre. I have recently had under treatment a case with the following family history.

Maternal grandmother suffered from goitre; mother had a goitre as a girl and died at 76, bedridden with arthritis, high blood pressure, and attacks of angio-neurotic oedema. The patient has three sisters—all of whom suffered from Graves's disease, one developing the disease a week after marriage. A brother was laid up for a long time, and it was thought he was going to develop Graves's disease, but he is now quite fit. The patient when 12 to 13 years of age had a very large goitre, and did not start menstruating until she was 17, when she had considerable dysmenorrhoea. At 19 the heart was said to be weak, and for the last few years she has suffered from tachycardia, auricular flutter, and fibrositis.

#### Association of Pregnancy with Rheumatoid Arthritis.

For years I have been struck with the fact that a patient with rheumatoid arthritis will give you the following history: that she became pregnant, and that during pregnancy she was very much better, but that during the puerperium all the symptoms returned with increased severity. This clinical fact has given me much thought. Now the thyroid is an active accelerator of metabolism, and its close connexion with reproduction is shown by its frequent physiological enlargement in the female—at puberty, marriage, and pregnancy, and sometimes at menstruation, and by its partial involution at the climacteric. During pregnancy great strain is thrown on the thyroid and the patient often becomes hypothyroidic for the time being. Then there is the association of the secretion of the corpus luteum and the pituitary, the internal secretion of the ovary stimulating the secretion of pituitrin; when the corpus luteum develops in pregnancy it checks this process in the interest of the foetus. Langdon Brown points out that the blood sugar curves of pituitary glycosuria and the glycosuria of pregnancy are similar, and suggests that the latter condition is due to pituitary disturbance, which is comprehensible, since pituitrin directly inhibits the action of insulin. This suggests that the normal holding up of pituitrin during pregnancy allows sugar to be stored up more readily in the interest of the offspring through the unchecked action of the insulin. Again, Cumberbatch and Robinson put forth the hypothesis that arthritis is directly or indirectly due to inactivity of the corpora lutea.

It is worth considering, therefore, whether the exhausted thyroid tends to reproduce the symptoms of rheumatoid disease, which have been held up in some way by the corpus luteum's inhibitory action on the posterior pituitary, and has thus restored the endocrine balance during pregnancy with amelioration of all the arthritic symptoms.

#### Arthritis of the Menopause.

The loss of the internal secretion of the ovary along with the partial involution of the thyroid produces a mild myxoedematous or hypothyroidic state. Clinically we know definitely that these cases improve with small doses of thyroid extract, some with the addition of ovarian extract and others with the addition of pituitary extract. I have particularly noticed how frequently these arthritic symptoms occur in cases where an artificial menopause has been induced and how improvement takes place under the above treatment.

Llewellyn<sup>12</sup> holds that there is a definite rheumatic diathesis due to endocrine instability, an instability which is observed in children and which is the forerunner of acute rheumatism. He bases his opinion on the following points, believing that:

1. The tendency of rheumatism to change its facies with the onset of puberty, the predilection of rheumatoid arthritis for the reproductive period and of osteo-arthritis and gout for the menopause or pre-senile epoch, suggest that the endocrine changes associated therewith account for the superficial diversity, but fundamental unity, of these affections.
2. Rheumatic children are all hypothyroidic.
3. Thyroid swelling very often ensues at the outset of acute rheumatism.
4. There is a definite geographical overlapping of goitre and acute rheumatism.

5. Acute rheumatism is an example of endocrine heredity. He quotes McCarrison: that the victims of simple toxic goitre are not only liable to Graves's disease, but, worse still, hand on to their children a condition of thyroid instability.

6. Both hypo- and hyper-thyroidism may follow acute rheumatism.

7. There is a higher incidence of rheumatism in goitrous than in non-goitrous children.

8. It is a clinical fact that some cases of acute rheumatism do not improve on salicylates until thyroid extract is added.

9. Subthyroidism spells suboxidation, and vasomotor instability implies irregularity in the supply and distribution of oxygen to the tissues.

Now, same may ask, where do infection and septic foci come in, and how is it that if you remove the septic foci the patient so frequently improves? The thyroid gland is one of the great defences against infection, and if the patient is already suffering from instability of the thyroid—either hypo- or hyper-thyroidism—the presence of an infective focus will not improve matters, and its removal may, and probably does, in many cases restore stability, in the same way as the removal of septic tonsils is so often the commencement of improvement in a case of Graves's disease.

Others may ask why it is that vaccines and protein shock are beneficial in these cases. Crammer answers this question when he says that the fact that many bacterial toxins stimulate the thyro-adrenal apparatus illustrates the curious and as yet unexplained phenomenon that in some infections the injection of non-specific vaccine, and even proteins, may have a striking therapeutic effect. The effect of the injection of these substances is to produce a typical rigor. The rationale of this so-called non-specific vaccine therapy, and protein therapy, would be that it elicits an increased functional activity from the thyroid adrenal apparatus—in fact, "sympathetic fever," which is one of the normal reactions of the organism against bacterial infection.

There is another point worthy of consideration—patients frequently tell us that their symptoms of rheumatoid arthritis commenced after a nervous shock, as an air raid, the death of a parent, an accident, etc. I have always believed that there is a psychological element in many cases of arthritis and endocrine imbalance, especially of the katabolic glands; their close association with the gonads supports this view. I have never been satisfied that septic foci were the sole causes of these diseases, but that behind it all there was a soil or diathesis which I believe to be connected with endocrine instability or imbalance.

## SEA-SICKNESS AND ITS TREATMENT.

BY

R. ALLAN BENNETT, M.D. LOND., M.R.C.P.,  
SURGEON, PACIFIC STEAM NAVIGATION COMPANY.

SEA-SICKNESS in its milder forms may be regarded as an occasion for jesting by those whom it does not trouble, but for some sufferers its anticipation may poison the prospect of a voyage, and it may cause prolonged discomfort or even death. A woman, aged 40, rather debilitated by fever, travelling in a ship in which I was a passenger many years ago, died after ten days of continual vomiting which no treatment could check. Such a catastrophe may be rare, but cases occur too frequently where suffering is prolonged for many days and the patient is reduced to a state of extreme mental and physical prostration.

No age, no condition of life, is exempt. Old people going on a voyage for the first time, sailors who have used the

sea all their lives, young people and infants—all are liable, although children below the age of 12 seldom suffer severely. The type of vessel seems to have no bearing on the matter. One person is unaffected in a sailing boat and suffers in a liner; a sailor immune in a battleship may be overcome by the movement of a destroyer.

Undoubtedly the chief predisposing cause of sea-sickness is anticipation; quite a strong-minded person may dread a voyage, while an impressionable passenger, who has made up his mind that he is going to be sick, may be seen to turn pale even as he crosses the gangway. I doubt whether migraine predisposes to sea-sickness. If the determining cause was a labyrinthine vertigo, it would be reasonable to expect that any latent condition, with vertigo as a symptom, would increase such liability; but in my series I can trace no connexion between the two. Conversely, in diseases of the internal ear a relative immunity to accidental disturbances might be expected, and, indeed, persons with perforated drums, previously martyrs to sea-sickness, have been freed by their disability. On the other hand, I have known two cases of double mastoid disease associated with severe *mal de mer*.

The sole cause of sea-sickness is not a disturbance of the harmony that normally exists between the cerebellum, the labyrinth, the eye muscles, and elsewhere, and their co-ordination in the centres. Sea-sickness may be caused, before the ship leaves the dock, by some revolting sensory impression, such as the smell of the bilge in old days, and, in modern times, the characteristic mixture of rubber and engine oil that pervades all but the largest vessels.

In a large proportion of cases there is chronic indigestion, with very often constipation, aggravated, maybe, by the excitement of preparing for the voyage, and, in cases where sea-sickness comes on late, by the excessive food consumed during the first days, which the stomach and bowels, weakened by lack of exercise, cannot deal with. In 88 out of 100 consecutive cases of sea-sickness the patients had over-eaten, either before or during the voyage; 74 were constipated, while in 80 the condition was mild and yielded to twenty-four hours' starvation and calomel. In this milder type the attack begins as a rule with yawning or sighing; sooner or later there is nausea; and the last straw is supplied by the smell of a cigar or the careless remark of a bystander. Retching continues with an empty stomach; the hands and feet are icy; the face is pale, and a cold sweat breaks out upon the head and cheeks. The pulse is feeble and slow, and the blood pressure is sensibly lowered; there is headache, generally occipital, and dizziness, varying from a slight unsteadiness to a vertigo which makes it difficult for the patient to keep his feet. The tongue is furred, and the mouth is dry, with a bitter taste. If in these circumstances the patient can keep about in the air he can hold out, but in 12 of the series the vertigo was so distressing as to make this impossible.

The type of vertigo varies for no apparent reason: the patient may fancy that he is moving and the surrounding objects are stationary; or vice versa. Closing the eyes may improve things or make them worse; plugging the ears with cotton-wool may, or may not, help. In some patients the mental effect is slight; in others there is a strong conviction that death is imminent, followed, as time goes on, by an unreasonable annoyance at its delay. In most cases, either as the result or in spite of the remedies given, the condition improves, and twenty-four or thirty-six hours will see the patient out of trouble. In a minority the condition may become serious: the vomiting and retching continue for many days; hiccup may supervene, the vertigo become intense, the mental depression increase, and the patient be reduced to a state of weakness which may end in death.

As in sickness following excessive smoking, a disordered action of the pneumogastric nerve appears to be responsible. Our sense of position in space is a function of the vestibular nerve and its centres in the brain and cerebellum; the central connexions of its nucleus with those of the tenth and oculo-motor nerves is very close, and it may well be that all are implicated in the production of these symptoms.

But the earlier symptoms may fairly be attributed to the pneumogastric nerve. They may never pass beyond this stage; vertigo is not an invariable, and never an early, symptom of sea-sickness.

#### TREATMENT.

Much can be done in the way of prophylaxis. The traveller who starts his journey with the intention of being sick is seldom disappointed, and he who spends his last days ashore in feasting and farewells will reap what he has sown. If the one would moderate his appetite, and the other practise auto-suggestion for a week before sailing, there would be fewer tragedies during the first days of a voyage. Before a long journey by sea it is wise to take two meals a day—breakfast and dinner—for a period of seven days, eating meat at one only, and avoiding all soups and made-up dishes. At midday take only bread and cheese and an apple. Take half the usual quantity of alcohol, drink water freely, and smoke but a little. The third day before sailing fast—eating nothing, but drinking water freely. That night and the following take a 5-grain blue pill, and the following mornings a Seidlitz powder or a dose of salts. No drugs are needed, but if the patient is exigent he may have a mixture three times a day containing 10 grains of bromide. Faith, however, is essential, and in the strength of it any man may go a-trawling forty days in the North Sea without discomfort. The trouble is that most people will make no effort to avoid a future inconvenience; they demand a cure without any help on their side.

During an attack of sea-sickness one remedy is as good as another if taken with confidence. Each traveller has his own specific: one takes bromide or chlorotone, or preparations of them under picturesque names; another clings to a peculiar form of belt; a third hangs an amulet about his neck; and a fourth plugs his ears with cotton-wool. In mild cases passengers should be encouraged to persevere with their own "cures," exception being taken to nitroglycerin and amyl nitrite, which may lower dangerously the already diminished blood pressure. Failing such a private supply, I prescribe tincture of iodine, 1 minim in a teaspoonful of milk every half-hour, and a mustard leaf to the pit of the stomach; bisenits and apples to eat; dry ginger ale to drink. However cruel it may seem, patients should be driven out of their cabins into the fresh air; only in the rarest cases is it necessary for them to stay in bed.

Such measures, with the help of time, will cure the majority of sufferers from sea-sickness, though the remainder may call for the most careful watching and tax every resource the ship provides. These others must be kept in bed in an airy cabin, protected as far as possible from the smells and noises which cannot be avoided even in the best ships. Swinging cots are unsatisfactory; they must share to some extent the movements of the ship; and there is, in addition, a certain amount of joggling, caused by the "give" of the elastic fittings, to the rods, which adds to the patient's discomfort. Hot bottles to the feet and a shade over the eyes are comfortable to most people, and there is virtue in mustard leaves over the stomach and on the back of the neck.

Injections of adrenaline—10 minims, repeated if need be—are helpful in cases where the blood pressure falls below 105, and the same is true of strychnine and camphor. Where vomiting is incessant the ordinary gastric sedatives given by the mouth are useless: the patient should be encouraged to drink freely of hot water, with or without sodium bicarbonate, which will relieve the bitter taste so often experienced, and serve to wash away the mucus which is abundantly secreted. It may be necessary to give rectal feeds, and nutrient suppositories are satisfying and convenient. I withhold morphine as a hypnotic except as a last resource, for it is apt to cause increased nausea as the sedative effect passes away.

Finally, in cases where the exhaustion is becoming dangerous I have recourse to a method which I have not seen mentioned. The patient is kept in a warm salt-water bath—temperature 90° to 95° F.—for half an hour, an hour, or longer. The relief is great and remarkably prompt; it cannot be ascribed to the general sedative effect,

but to the mechanical changing of the patient's environment. The specific gravity of the water is 1020, and the body is supported very lightly on the buttocks, the shoulders, and the back of the head, with the toes just touching the end of the bath to prevent the legs from floating free. The bath itself shares the rolling and pitching of the ship, but the water it contains has not time to respond, and keeps its level, with the patient immersed in it partaking of its relative immobility. Watching a bathful of water in a rolling ship the surface appears to slant this way and that with the movement of the vessel, but a spirit level floated on a cork raft will show that the water is unaffected. If the ship is pitching the long axis of the bath should be fore and aft; if rolling, athwart ship. The patient must not be able to see the apparent oscillation of the water, and the eyes should be bandaged—voluntary shutting is not enough, since in many cases vertigo is increased by the effort of closing the eyelids. If this procedure is carefully followed it always, in my experience, lessens the dizziness and gives relief, which is valuable in severe cases, and often permanent.

### FATAL SUPPRESSION OF URINE CAUSED BY LATENT HAEMAGGLUTININS.

BY

GEOFFREY SHERA, M.A., M.D., B.Ch. Cantab.,  
M.R.C.S., L.R.C.P.,

PATHOLOGIST TO THE PRINCESS ALICE MEMORIAL HOSPITAL, EASTBOURNE,  
AND TO THE EAST SUSSEX COUNTY MENTAL HOSPITAL.

Following blood transfusion with an apparently compatible donor, the occurrence of a condition akin to blackwater fever, both in its symptoms and morbid anatomy, and sometimes with a fatal issue, is fortunately uncommon. Blaker and Dodds (1925)<sup>1</sup> record with illuminating detail two such fatal cases, and add very valuable experimental observations. Keynes<sup>2</sup> refers to a case reported by Bernheim<sup>3</sup> where, after transfusion, haemoglobinuria occurred, and progressively increased until the function of the kidney became so much interfered with by deposits of haemoglobin or damaged corpuscles that the patient died with suppression of urine and all the signs of uraemia. Dyke<sup>4</sup> mentions two cases of haemoglobinuria due to a Group 2 case being mistaken for a Group 4 owing to a low titre, Group 3 serum being used for the preliminary testing. Keynes<sup>2</sup> also refers to non-fatal transient haemoglobinuria, and I myself have noted this phenomenon on two occasions.

It is of interest in this connexion to note that Yorke and Nauss,<sup>5</sup> working on the pathology of blackwater fever, injected rabbits with haemoglobin and produced intrarenal obstruction. Blaker and Dodds, repeating these experiments, found that in order to produce renal precipitation the urine must be acid and contain sodium chloride to the strength of at least 1 per cent.

Comparing three fatal cases, one of mine and two of Blaker and Dodds,<sup>1</sup> all have certain clinical features in common: onset within a few hours; pyrexia 99° to 104°; jaundice; methaemoglobinuria; and lumbar pain with symptoms of uraemia. One case was fatal in four days, my case in eight days, and the third in nineteen days. Nitrogen retention was apparent, and the cases took on the picture of latent uraemia.

One of the Blaker and Dodds cases showed a blood urea of 102 mg. per cent. on the fourth day, 178 mg. on the tenth day, 400 mg. on the sixteenth day, 618 mg. on the seventeenth day, and 803 mg. per cent. after death. The second showed a blood urea of 287 mg. per cent., and my case on the third day showed 174.6 mg. per cent.

#### Clinical History of the Present Case.

A woman, aged 36, was admitted to the Princess Alice Memorial Hospital, under Mr. A. H. Crook, with a history of five and a half weeks' amenorrhoea, except for a slight "loss" four days before admission. She had a black discharge, with abdominal pain, constipation, and vomiting. She was very blanched and restless, and had the obvious appearance of severe haemorrhage of some

duration. She was very tender and rigid in the left iliac fossa, and there was dullness in the flanks, with a fluid thrill. Her pulse was 140, the respirations 28, and the temperature 97.5°.

During the operation a pint of the husband's blood was transfused after preliminary cross-testing of the patient's serum against the donor's cells for thirty minutes at room temperature and with the aid of the microscope. Both donor and patient were identified as Group 4 (Moss). At the operation the abdomen was opened by a median incision and much dark blood and clots oozed out, also a small foetus. The right Fallopian tube was found to be ruptured; it was tied and removed. The clots and blood were swabbed out and the abdomen was closed. The wound remained clean subsequently, and the patient showed very slight signs of reaction, the temperature rising only to 100.8°.

#### After-History.

On the next day (June 20th, 1927) the general condition of the patient was very good; she talked cheerfully, but slight icterus was noted, and there was complete suppression of urine. She complained of some abdominal pain, which was probably renal. A catheter was passed and 6 oz. of blood-stained urine were obtained, full of blood debris. The pulse was 116, the respirations 24, and the maximum temperature 99.5°.

June 21st. Suppression was complete. A catheter yielded only 2 oz. of blood-stained urine. The maximum temperature was 99.5°; the pulse 100, and the respirations 24.

June 22nd. Only 1½ oz. of urine were obtained by catheter. Hot-air baths, rectal salines, pilocarpine, and alkalis were given without effect. The blood urea was found to be 174.6 mg. per cent. The pulse was 100; the respirations 24, the temperature 99.2°, and the van den Bergh reaction was an indirect positive.

June 23rd. Only 2½ oz. of urine were removed by catheter. Lumbar pain was now marked. The pulse was 92, the respirations 22, and the temperature 98.6°.

June 24th. Only 1 oz. of urine obtained. Abdominal distension was noted, and diuretic was given without effect. The pulse was 88, the respirations 20, and the temperature 98.4°.

June 25th. Signs of uraemia appeared in addition to haemolytic jaundice, and the patient became drowsy and irritable. The systolic blood pressure was 119 and the diastolic 78. The temperature was subnormal.

The patient died suddenly on June 27th.

#### Post-mortem Examination.

The necropsy was performed in my absence by the house-surgeon, Dr. J. F. Lang. Early adhesions were evident between the wound and the site of removal of the ruptured ectopic gestation. The kidneys were enlarged and of a pale coffee colour, with engorgement showing as striations in the medullary rays. The capsule stripped readily. The cortex was diminished in width; it contained some engorged vessels as striated lines, but the most striking feature was the marked engorgement of the medullary rays. Microscopical sections revealed intense engorgement of the capillaries and tubules. Bowman's capsules gave evidence of compression, and the tubular cells showed flattening and pressure atrophy with disappearance of many of the nuclei. The tubules were full of red blood cells or debris, and there was cloudy swelling where the condition was furthest advanced. The development of fine, intertubular connecting tissue was visible. The kidney was clearly the seat of advanced parenchymatous changes due to lack of nutrition of the cells, which was in turn due to pressure atrophy and toxic changes. Eosin-staining material in masses and granules was evident in parts. The bladder contained coffee-ground material. In regard to the liver, the bile ducts were markedly outlined macroscopically, and the picture of chronic venous congestion was present (nutmeg type). Microscopically there were similar changes due to intense venous congestion with consequent pressure atrophy of the cells leading to parenchymatous degeneration, as evidenced by cell vacuolation and loss of nuclear staining. The spleen was very congested. Other organs were macroscopically normal.

The cause of death was therefore presumably uraemia due to mechanical blockage of the kidneys and liver by blood cell agglutination proceeding slowly and progressively owing to the presence of small but effective amounts of agglutinin in the patient's serum. Undetected incompatibility was obviously the cause. The patient and donor were apparently both Group 4, but a subsequent repetition of the cross-test (donor's cells and patient's serum) revealed at the end of sixty-five minutes a definite macroscopic agglutination. It will be remembered that thirty minutes had been allowed, and in the desperate condition of the case no longer delay was permissible. In the paper by Blaker and Dodds<sup>1</sup> it is recorded, in connexion with their first fatal case, that there had been some question as to the group interpretation, and in regard to the second, both donor and recipient were apparently Group 4, but subsequently a cross-test showed the patient's serum to agglutinate the donor's cells. On more than one occasion I have found that an apparently Group 4 donor's cells were agglutinated by a patient's serum (apparently also Group 4). A similar effect was recently noted by Dr. Dyson of St. Mary's Hospital.

Dyke<sup>4</sup> has noted that Group 3 serums are sometimes deficient in agglutinins, whereas others are of high titre. Professor Freuchen of Copenhagen informs me that, in a series of 400 transfusions, he has met the same phenomenon on four occasions, and the solution of the difficulty is the invariable marketing of high titre Group 3 stock serums—an observation recommended to commercial firms for attention.

Meanwhile, we have the cross-test. Dyke<sup>4</sup> quotes the technique of the American Society of Immunologists, which considers that thirty minutes at room temperature is sufficient prevention of untoward results; the present case affords evidence that this time may be insufficient. My own rule is now to incubate the bloods at 37° C. for one to one and a quarter hours in a damp chamber; the hollow-ground slide is placed in a Petri dish lined with damp filter-paper. To save time, if all is well at the end of twenty minutes the donor is bled, and when seventy-five minutes has elapsed from the time of mixing the bloods, and not before, unless the case is so desperate that the extra risk must be taken, the actual transfusion is commenced. Hitherto all trouble has been obviated, and this I believe to be the only safe method of procedure until such time as reliable high titre Group 3 serums are marketed.

#### Animal Experiments.

The value of animal experiments in elucidating the causation and indicating the necessary preventive measures in respect of this tragic condition will be apparent. Yorke<sup>2</sup> found that in order to produce precipitation of injected haemoglobin in the kidneys a dry diet (in rabbits) was essential; if they were fed on a wet diet of greens it did not occur. Blaker and Dodds<sup>1</sup> found that rabbits would pass an acid urine if fed on greens. In one case with an acid urino partial renal blockage occurred with a blood urea of 78 mg. per cent. The rabbit on wet diet had a blood urea of 35 mg. per cent., and passed a red urine without blockage. The factors in precipitation were found to be: (1) An acid reaction (pH 5-6) which converted the pigment oxyhaemoglobin into methaemoglobin, and then probably into acid haematin. (2) Sodium chloride, provided it was in a concentration of not less than 1 per cent.

In paroxysmal haemoglobinuria and blackwater fever there is a similar mechanism with similar pigment casts, but the amount of haemoglobin liberated is smaller, and in these, as in the lesser degrees of transfusion haemoglobinuria, the kidney is generally able to weather the storm.

#### Therapeutics.

Blaker and Dodds<sup>1</sup> recommend, on theoretical grounds, the exhibition of alkaline diuretics and transfusions of sodium carbonate. It is obvious that what must not occur is an acid, concentrated urine. In my case we tried alkaline diuretics, but, it is probable, not intensively enough. It is sufficient to say that if the urine can be kept alkaline for a few days, experiment has shown that all will be well and no renal blockage can occur.

Finally, the transfusionist must have ample warning, so as to allow the maximum amount of time necessary for cross-agglutination.

Whereas no originality is claimed for anything in this paper, except perhaps the histo-pathology of the liver in this instance, its excuse is to draw attention to the uniformity of the lesions found after death, to the valuable experimental work of Yorke, Blaker, and Dodds, and to show the necessity for a prolonged cross-agglutination test whenever practicable, and so to indicate certain means by which the tragedy of delayed incompatibility may be averted. In conclusion, I desire to thank my colleague Mr. Arthur H. Crook for permission to publish this case.

## VACCINES IN THE TREATMENT OF GONORRHOEA.

BY

E. D'ARCY MCCREA, M.D., M.Ch.

At the venereal diseases clinic of Salford Royal Hospital it was customary during the years preceding 1924 to treat every case of gonorrhoea by a course of detoxicated gonococcal vaccine in addition to the ordinary routine treatment; however, since December, 1923, the vaccine has been discontinued. The vaccine treatment appeared to have a certain definite influence in the prevention and cure of the various complications and in shortening the period of treatment. We have therefore thought it of interest to make a comparison—so far as it is possible—between the results obtained during the years 1922-23 on the one hand and those of 1924-25 on the other.

#### Routine Treatment.

The clinic permits of the attendance of patients thrice weekly, and the treatment (vaccine excepted) has remained unchanged from 1922 to 1925 inclusive. A urethral smear from each new patient is examined for gonococci, and if urethritis is present the patient is put on a mixture containing 10 grains of potassium citrate, 5 minims of tincture of belladonna, and 1/2 oz. of infusion of buchu, to be taken thrice daily, is supplied with an easily sterilized outfit containing a syringe, and with potassium permanganate lotion 1 in 8,000, and is given a sheet on which are printed all the necessary instructions; after a short period the lotion is strengthened to 1 in 6,000, and later—some four to six weeks after the initiation of treatment—a two-glass test demonstrates the presence or absence of a posterior urethritis. Posterior urethritis is treated by deep irrigation twice weekly with potassium permanganate lotion 1 in 6,000, after the method of Janet, and by prostatic massage once weekly; the irrigation is varied by employing zinc permanganate 1 in 6,000; or silver nitrate 1 in 10,000, and sometimes mercury oxycyanide 1 in 2,000. The progress of the patient is estimated by the two-glass test and by search for the gonococcus, both in films and by means of cultures.

#### Standard of Cure.

Cure is not accepted unless satisfactory tests are obtained during a period of six months after treatment has been discontinued, and before the final test a return to alcohol is permitted. It is very necessary to define the standard of cure; each doctor has his own criterion, and in the past the cessation of the urethral discharge was often accepted as proof of cure. It is preferable to err on the side of strictness and so avoid the possibility of those lamentable happenings which otherwise sometimes occur.

#### The Two-glass Test.

The two-glass test is carried out as follows: the patient holds water for three hours prior to examination; he then passes the first specimen, and after prostatic massage the second; both urines are at once centrifuged and examined microscopically, the average number of pus cells in a field being reported. From this count we determine the presence or absence of posterior urethritis; six to seven pus cells to a field, in the second urine, is the figure which we find from experience to indicate approximately the dividing line between a posterior urethritis and one limited to the anterior urethra—that is to say, a figure above this number denotes an extension of infection to the posterior urethra. For a cure the number in the second glass should not be above three, in a few patients four or five, the ideal being nil in both specimens.

#### Vaccine Treatment.

The vaccine treatment, which was added to the routine procedure during the years 1922-23, consisted of two courses of vaccine—the first of ten injections of a residual pure gonococcal vaccine at weekly intervals, and the second, if posterior urethritis developed, of ten injections of a residual mixed vaccine of gonococci, streptococci, staphylococci, and

*Bacillus coli*, commenced during the third or fourth month. The vaccines were prepared by Dr. C. E. Jenkins, pathologist to the hospital.

#### Results of Treatment.

The total number of new patients for the years 1922-25 inclusive was 424; this figure includes only those in whom the gonococcus was identified, and consequently, although the total figures are considerably reduced, other forms of urethritis are confidently excluded. Of these 424 patients 150 attended for a period of one month or less and then disappeared, leaving 274 for consideration—134 of 1922-23, and 140 of 1924-25. In one-third of these patients it was not the first attack of gonorrhoea. The accompanying table illustrates and serves to compare the results of treatment; the figures are, however, probably more useful for purposes of comparison than as statistics, since a proportion of the patients did not complete their treatment. The numbers dealt with in each period remain, however, approximately equal. We believe that if home treatment by means of an outfit were replaced by hospital treatment at more frequent intervals much more satisfactory results would be obtained.

	1922-23 (Vaccine).	1924-25 (No vaccine).
Number of patients ... ..	134	140
Number without posterior urethritis	26=19%	16=11%
Number with complications...	24=18%	42=30%
Number cured ... ..	66=49%	45=32%
Average period before a negative test	5 months	7½ months
Average incubation period 7 days.		

The figures in this table require some consideration. First, it is obvious that but few patients escape a posterior urethritis; secondly, the numbers cured are to some extent misleading, for of those who do not appear as cured the majority ceased to attend before a negative test was obtained, and many of these were about to reach this stage. The real interest lies in the comparison, and it is seen at once that the percentage of complications (arthritis, epididymo-orchitis, and rheumatism) was greater in 1924-25, the percentages of cures less, and the period of attendance before the first negative test was obtained longer than in 1922-23. It is again emphasized that save for vaccine treatment the routine was in all respects the same during these four years. Some small variations may be expected between different years, but to us it appears justifiable to attribute these marked differences to the vaccine treatment.

### COMPLETE INVERSION OF THE UTERUS: RECOVERY.

BY

DANIEL M. DONOVAN, L.R.C.P. AND S.ED.,  
PHYSICIAN TO THE COUNTY OF CORK LYING-IN HOSPITAL.

THE very rare occurrence of the condition present in the patient whose case is described below is sufficient warrant for placing it on record, and particularly so since the treatment adopted was followed by complete recovery. According to most authors, in only 30 per cent. of these cases is such an outcome to be expected.

A married woman, aged 37, was admitted to the Ennville Lying-in Hospital, Cork, at 8 p.m. on September 17th, 1927, in labour; she complained of great pain on micturition, and the urine was found to contain blood. She was apparently a strong healthy woman, was the mother of ten living children, and had had three miscarriages. Her menstrual history was normal, and she had never suffered from any serious illness. She had a bad time on the occasion of the birth of her first child, the labour extending, according to her own account, over three and a half days. The placenta was retained and had to be removed manually.

At 1 a.m. on September 18th she gave birth to a male child weighing 11 lb. Profuse bleeding occurred after the child had been born, and the patient collapsed. A hypodermic injection of 1 c.c.m. of pituitrin was administered, followed by brandy. After the lapse of half an hour expression of the placenta by the "Dublin method" was attempted, and sudden and complete inversion of the uterus took place; there had been no traction

on the cord. Shortly before 2 a.m. I was summoned by telephone and found the patient very bad indeed. The pulse was imperceptible, the face was covered with a cold clammy sweat, and the respirations were faint and fast. I was informed that a peculiar placenta was half delivered, and discovered the uterus with the placenta covered by membranes completely external to the vulva, and extending down nearly to her knees. It was quite evident that no time must be lost if the patient's life was to be preserved. I hastily came to the conclusion that anaesthesia was out of the question; the time that would elapse before I could have the assistance of my colleagues would have been fatal. The serious, almost dying, condition of the patient did not warrant my administering an anaesthetic and performing the necessary manipulations myself. By doing so I could not maintain satisfactory anaesthesia, and, moreover, it would have been impossible to keep my hands from becoming infected. In any case I did not think the patient was fit to take an anaesthetic. Having covered the lower abdomen and thighs with towels wrung out of normal salt solution I proceeded as follows. From where I could feel the edge of the placenta I tore through the membranes with my finger in the mid-line and completely swept them off the uterus all round. I then proceeded to separate the placenta and found that it was very adherent at the margin, but that towards the centre it had already separated from the uterine wall to a considerable extent; the cavity thus created had filled with blood, which by now was one large clot. I washed over the surface of the uterus with hot salt solution, and seizing the organ with my two hands I endeavoured to reduce its size by squeezing the blood from it. I kept up this pressure for a few minutes, and then, removing my left hand, grasped the now much diminished uterus with my right hand, and was able to return it completely within the vagina. Gentle upward pressure then at once restored it to its normal position.

Having replaced the uterus I now turned my attention to the general condition of the patient, who was practically unconscious and apparently dying. Another 1 c.c.m. of pituitrin was administered hypodermically. Two pints of normal salt solution containing 1 drachm of adrenaline solution was injected into the axillae, and the patient was ordered 1/30 grain of strychnine with 1/100 grain of digitaline every four hours hypodermically. She was also given salt solution by the rectum every four hours. She regained consciousness at 5 a.m., and by that afternoon had apparently got over the grave shock, but she then complained of severe headache.

Her temperature that afternoon was 97.6° F., the pulse rate was 120, and the respirations 32. Rectal salines and hypodermics of strychnine and digitaline were discontinued. The temperature gradually rose to between 101° and 102° F., and she had a rigor on the third day. She was then given an intrauterine douche of cyllin solution, which was repeated every day for four days, and subsequently every alternate day for fourteen days. On the intervening days the vagina was douches with cyllin solution. She was also given 1 drachm of the liquid extract of ergot twice daily during this time. The temperature gradually subsided and she was quite well and out of bed on the twenty-second day. No further complications occurred, and she left hospital at the end of four weeks quite well.

Complete inversion of the uterus is said to occur only once in 250,000 cases, and is usually put down to the following causes: (1) traction on the cord; (2) too vigorous compression of the fundus; (3) sudden delivery, especially if the mother is standing; (4) exertion after delivery, as in coughing; (5) short cord of whatever etiology.

In this case none of these causes existed, except that pressure on the fundus was tried, as stated, to express the placenta. This, however, was performed by a highly skilled and very experienced nurse, and for that reason may be eliminated. Again, the condition is said to be more common in primiparae, and my patient had given birth to ten children.

Opinions are divided as to whether the placenta should be separated from the uterus before attempting to replace the latter. I have no doubt that if I had attempted replacement without previously removing the placenta I should have had considerable difficulty in doing so; if I had succeeded I should then have had much more trouble in removing the very adherent placenta with the uterus *in situ*, and the extra time involved would probably have been fatal to the patient.

The fact of the patient not being anaesthetized has been already explained. It would no doubt have made things easier for me if the patient had been under the influence of an anaesthetic, but I am satisfied that delay was out of the question, and that speedy replacement of the uterus and treatment of the profound shock gave the patient the only chance, and that a poor one, of recovery.

I am indebted to my colleague Dr. P. J. O'Brien, for whom I was acting on this occasion, for permission to publish this case. To him also is due a large measure of praise for the ultimate recovery of the patient, since he took over the case from me on the day after the birth, and continued in attendance on her till she left hospital.

IDENTIFICATION FROM A FINGER-TIP  
REMOVED BY A BITE.

(With Special Plate.)

A rascal broke into a house in an Egyptian village with intent to rob or with some other intent. During his peregrinations he entered the room of a woman, and she, in self-defence, bit his finger with sufficient force completely to sever the tip. The visitor made his escape without being recognized, as the place was in absolute darkness.

Fortunately the lady did not swallow the finger-tip, but handed it over to the police when she laid a complaint the following morning. Instructions were issued to watch for anyone with an injured hand, and ten days afterwards a man with his right hand wrapped up in a handkerchief was arrested on suspicion at a railway station in the district. It was ascertained that he had lost a portion of his right index finger, and he was sent to the medico-legal department, together with the seized finger-tip, in order to ascertain whether the portion bitten off belonged to the injured hand.

On examination of the accused person it was found that the injury to the finger had been caused by a bite. X-ray examination of the hand showed that the bite had passed through the base of the terminal phalanx of the index finger. X-ray examination of the specimen showed that the distal portion of a phalanx was present. A comparison of the finger-nail on the specimen with that of the left index finger of the accused showed them to be exactly similar.

There was thus an extremely strong presumption that the man arrested was the guilty person. The accused was then asked if he had been in trouble before, to which he replied that on a previous occasion he had been arrested on a false charge—that was in 1919. The antecedents bureau was immediately asked to supply the finger-prints taken on that occasion, and on comparison of the print of the right index finger with the tip bitten off it was found that the patterns and ridge details were identical.

In the Special Plate Fig. 1 shows the tip and Fig. 2 the original finger-print. Seven points of identity have been marked, but the reader will be able to trace a great many others. This completed the absolute identification of the accused.

SYDNEY SMITH, M.D., D.P.H.,  
Professor of Medical Jurisprudence,  
University of Edinburgh

EMBOLUS OF THE SUPERIOR MESENTERIC  
ARTERY.

The brevity (and in some cases the absence) of description in most of the standard surgical textbooks of the signs and symptoms liable to be found in embolic obstruction of the superior mesenteric artery prompt me to place on record the clinical history of a patient under my care, who recently developed this complication.

A lady, aged 79, first consulted me on account of "palpitations and flatulence." On examination her heart was found to be fibrillating. Until the previous few days she had led an active life, interrupted by no special illness. The heart was slightly enlarged, but no bruit was detected. She was instructed to rest in bed, and was given 15-minim doses of tincture of digitalis three times daily. In two days she considered herself better, and thenceforward the heart steadily improved. By the tenth day the pulse had become regular and strong, and she thought her troubles were ended. She was, however, kept in bed, the digitalis dosage being reduced to 10 minims. Two days later there was a sudden attack of very severe abdominal pain, referred mainly to the epigastrium. It occurred soon after her midday meal, which had consisted of some milk pudding and a banana, and a few minutes later it was followed by vomiting and diarrhoea. Her condition was unchanged throughout the afternoon and early evening. The vomit at first consisted of gastric contents and subsequently of bile-stained fluid. The first stool was faecal, but within half an hour of the onset of the pain the patient was passing blood-stained mucus. The vomiting and diarrhoea were severe. The abdomen remained soft, and no tender area developed. The pain was described as colicky, and persisted

mainly in the upper half of the abdomen. There was no suggestion of collapse, the patient repeatedly altering her position in bed, and at times getting out in attempts to ease the pain. The pulse remained strong and steady. Rectal examination was negative. No drug alleviated the symptoms till about 6 p.m., when two large doses of bismuth were retained, apparently easing the pain and stopping the vomiting.

Towards 9 p.m., however, the pain regained its original severity and was accompanied by repeated retching or vomiting and occasional diarrhoea, the stools now being smaller, but still consisting of blood-stained mucus. At midnight no fresh signs had developed in the abdomen and the pulse rate remained unchanged. An injection of morphine was given, and for the next four hours relief was obtained. At 4 a.m. the pain recurred, though to a less degree. The abdomen was now a little tender over the caecum and ascending colon, but still there was no local guarding or rigidity, no visible peristalsis, and no apparent distension or free fluid. Throughout the morning the pain continued with occasional short intermissions and occasional vomiting, the vomit being yellow fluid. The bowels were not again opened. The abdominal signs remained unchanged, but the pulse rate increased from 70 to 94, though still remaining strong and regular. At 2 p.m. the tenderness over the caecum and ascending colon had increased considerably, the abdomen appeared rather distended, and free fluid was present. The patient complained of some pain in the sole of the left foot. Half an hour later faecal vomiting commenced and the right side of the abdomen became moderately rigid. Arrangements were now made for the patient's admission to the Gloucester Royal Infirmary. Just prior to her departure from home the left radial pulse became obliterated, and shortly afterwards numbness and coldness of the left hand and forearm developed.

On admission to the infirmary the patient was seen by Mr. A. Alcock, who diagnosed the condition as being embolism of the superior mesenteric artery. By this time distension had increased very considerably, the whole abdomen was rigid and tenderness generalized. Mr. Alcock opened the abdomen under local anaesthesia; gangrenous small intestine was found, and the diagnosis was confirmed. The wound was closed, and the patient died the following day.

This case not only affords an illustration of the clinical picture liable to be found in embolic obstruction of the superior mesenteric artery, but it also shows the importance of a thorough consideration of every symptom, however small, before coming to a conclusion. The first clue to the correct diagnosis was presumably the pain in the foot, but at the time of its occurrence I attached little importance to this symptom, and thought that the cause of all the trouble was probably a volvulus or possibly an intussusception.

HAROLD J. SELBY, M.R.C.S., L.R.C.P.

Newnham-on-Severn.

## RECOVERY FROM TETANUS.

The case of tetanus described by Dr. J. D. Chisholm and Dr. Arnold Renshaw (February 4th, p. 175) recalled to my mind a case in my own experience.

A Hausa man was brought to hospital on a lorry; when I saw him first he was resting on his abdomen and chest, with both head and heels raised and with marked risus sardonius. He was admitted to a single ward, and further investigation showed that there were suppurating cliggers in the toes of both feet. Left to himself the patient lay on his right side, with marked arching of the back and retraction of the head. He was unable to separate his teeth, but could move his arms and hands. His temperature was not raised, but the pulse rate was increased. On attempting any examination or on the slightest disturbance there was severe spasm of the spinal muscles and risus sardonius. Pain seemed to be most intense in the lower cervical and lumbar regions, and also in the abdominal muscles. It was impossible to obtain a history of the sickness, but apparently he had been helpless for about five days before admission.

The suppurating toes were treated and a saporific given; that night the patient slept well. Next day there was very little change except that the pulse rate was slightly diminished. He took liquid food well. Potassium bromide was given in moderate doses, at first four-hourly and later three times daily. After four days the wounds were healing and the spasms were less severe. Convalescence proceeded slowly but favourably till in the third week the patient was able to walk with only slight stiffness of the back. He was about to be discharged when he passed a large quantity of tapeworm; after helminthic treatment he left the hospital apparently in normal health.

Although on admission this patient had been considered moribund, complete rest and freedom from disturbance, together with sedatives and dressings to the feet, were the only lines of treatment open to us. I despaired of his recovery, thinking that even had antitetanic serum been available the case was too far advanced for it to be of use. I had been led to this conclusion by the earlier cases which I had previously unsuccessfully treated with large doses of the serum. I have never before seen recovery in such a severe case.

## CLINICAL AND SCIENTIFIC PROCEEDINGS.

## CITY DIVISION.

*Fibrositis.*

At a meeting of the City Division, on April 3rd, at the Metropolitan Hospital, with Dr. PHILIP HAMILL in the chair, Drs. T. H. G. SHORE and G. T. LOUGHBOUGH of the Metropolitan Hospital read papers on the treatment of fibrositis.

Dr. SHORE recalled that in the report of the Ministry of Health, 1924, "rheumatic" diseases were stated to account for one-sixth of the total invalidity of the working population. Half of this was stated to be due to joint disease, and the bulk of the remainder comes under the head of fibrositis. Chronic rheumatism, muscular rheumatism, and fibrositis had been defined by Stockman as "a condition of chronic inflammation of the white fibrous tissue of the fasciae, aponeuroses, sheaths of muscles and nerves, ligaments, tendons, periosteum, and subcutaneous tissue occurring in all parts of the body, and giving rise to pain, aching and stiffness, and other symptoms, the result of preceding general infections or of local inflammations or injuries." The name "fibrositis" was first given by Gowers in 1904. From Stockman's histological investigations it appeared that the local lesion in the fibrous tissue consisted of an inflammatory hyperplasia, scattered in a patchy manner in the affected parts. At first was seen a localized collection of fibroblasts and leucocytes, with a serous or sero-fibrinous exudate; later on, young fibrous tissue was formed. When acute exacerbations occurred the tissue became swollen, and more inflammation and exudation was seen, with, later, more fibrosis. Like all newly formed pathological fibrous tissue this contracted, and pain was produced by the pressure of the contracting tissue on nerve endings and on the nerves themselves; partial strangulation of vessels accentuated the trouble. The tissues affected were those which carried the blood vessels and acted as insulators for the nerves, but derived themselves very scanty supplies from either. Vessels supplying the actual fibrous tissue were very small, and were, therefore, especially liable to be affected if the cause of the trouble was of an embolic nature. In chronic cases, in which foci had been inflamed several times, fibrous thickenings, somewhat resembling the nodules of acute rheumatism, might be found; these had been called "tophi rheumatici." They appeared to be capable of interfering with the vessels conveying blood to more distant parts, either directly by pressure or indirectly by deranging the vasomotor mechanism. As a result muscular weakness and muscular wasting might be produced. The initial lesion in fibrositis was histologically of the same nature as the rheumatic nodes of Aschoff in the myocardium. The cause of the fibrositic lesion might reasonably be expected to be similar to that of rheumatic myocarditis. Although no definite causal organism was known it was probably resident in the apices of infected teeth and the tonsils, or, less commonly, in the prostate, the urinary tract, the cervix uteri, the gall-bladder, and, perhaps, the intestine. Infections such as "colds," influenza, gastro-intestinal catarrhs, and infections of the accessory air sinuses were enough to light up the trouble in the primary foci, and indiscretions of diet, constipation, and gout might determine an attack. Dr. Shore suggested that the actual cause of the pain was of a vascular nature, either a vasoconstriction by toxæmia or a structural interference with the vasomotor mechanism, or, more likely, both operating together. The various local measures were directed to increase the blood supply to the part, and when they relieved the condition they did so in that way. Massage should always be applied to the most painful parts, for it was there that permanent fibrous thickenings existed, which massage alone could disperse. Others were faradism, ionization, diathermy, radiant heat, and ultra-violet light, which probably acted mainly in the same way. In cases in which intoxication from constipation had a share saline aperients were valuable. Certain drugs which had diaphoretic actions by virtue of being vaso-dilators relieved

fibrositic pain; such were ammonium acetate, spiritus ætheris nitrosi, and Dover's powder. At one time quinine was much used for this purpose, and on account of its cost was often adulterated with salicin. This led to the use of salicin, and later the salicylates and aspirin; at about the same time the coal-tar derivatives phenazone and phenacetin became popular, a very favourite mixture being aspirin, phenacetin, and caffeine. When gout could be shown to be a factor in the case colchicum and the more recent cinchophen were useful for a time, but could not be expected to act after their function of eliminating excess of uric acid has been performed. These drugs should be employed in short bursts only. Guaiacal carbonate was useful in some cases. Calomel and blue pill were very useful internally, and the mercuric iodide ointment externally. Dr. Shore had found potassium iodide disappointing, though Graves found his own attack passed off so that he noticed relief coming almost hourly, after he had suffered for several weeks on other remedies. Iodine had been used for intramuscular and intravenous injection, as well as externally as a counter-irritant. Methyl salicylate, menthol, and camphor, though their smell was objectionable to some, were quite good as external applications. Fibrolysin had proved very disappointing in the hands of most who had tried it. Vaccines, whether "stock" or autogenous, had also not been very beneficial.

Dr. G. T. LOUGHBOUGH confined his remarks to the physical treatment of fibrositis, including the mechanical, electrical, and radio-therapeutic procedures. Skilled massage helped to relieve muscle spasm in the acute stage and to induce hyperæmia of the affected tissues; in the more chronic cases it freed tissues matted together by old exudate, loosened stiff muscles, and so enabled them to increase the blood supply both to themselves and the parts around them, and by actual attrition removed the fibrous nodules associated with this disease. Electrically driven vibrators were sometimes used, but their action could not be accurately controlled. Of true electrical methods ionization was still used, but the actual amount of drug introduced through the skin in ionic form had been proved to be so small, and also to be carried at once by the superficial blood stream, that it could not possibly have any effect. Any benefit which occurred must be due to the steady passage of current through the affected tissues: this, if steady and prolonged long enough, would undoubtedly reduce effusions and exudates, first by the formation of ions, and secondly, by causing these ions to move in a constant direction through the tissues. This process altered the chemical constitution of the effusion, and helped reduction by changing the osmotic pressure. It was being used for fractures at the Royal Free Hospital with much subsidence of the swelling and earlier relief of pain. The sudden contractions which occur as the result of the stimulus of intermittent currents loosened the adhesions if present, and slightly increased blood flow would occur in the muscle. Radium and x rays were penetrating, high-power rays, and their action was too destructive to be of any use in fibrositis. In spite of its superficial absorption, ultra-violet radiation was an extremely potent agent in the cure of fibrositis; the explanation of this was probably: (1) the benefit was partly due to the general tonic action; (2) the heat produced by absorption travelled inwards by conduction, the absorption taking place deep to the superficial blood stream; (3) the hyperæmia produced also spread inwards by reflex action; (4) the apparatus used also produced waves of many other wave lengths going right down into the infra-red, and it might be that it was from these other rays, or the combination of them all, that the benefit was produced. The rays from the sun or its substitutes, the carbon arc and various therapeutic lamps, acted mainly by their general tonic action on the blood; the deep effects were secondary to this or depended on the presence of rays other than those of visible light. Heat in various forms had long been used as part of the cure of fibrositis. In order to get energy to the deeper affected parts either diathermy currents or the most penetrating infra-red rays must be used. Diathermy was a current of such high frequency that it could not be felt: considerable power could therefore be passed through the patient, which by the resistance

of the tissues was changed into heat. Heat, generated in the deep tissues, brought rapid relief by vaso-dilatation and increased blood supply; secondly, heat acted as a catalytic agent, starting chemical reactions such as the oxidation of products of fatigue and disease; thirdly, energy by molecular and atomic collisions formed new ions, which in their turn altered the electrical charges of atoms and the chemical and physical state of molecules, as, for example, reduction of the viscosity of exudates and the increase in the permeability of membranes. At present, the most useful physical aids in the treatment of fibrositis were, in the acute stage, diathermy to produce internal heat, and ultra-violet rays, preferably from a cored carbon arc which gave almost the whole range of ether waves, the shorter for their tonic effect, and the longer infra-red rays for the heating of the deep tissues in a way similar to, or perhaps better than, diathermy. In the more chronic stage continuance of the above two methods was required, with the addition of skilled massage to remove adhesions and for the unmatting of tissues.

## Reports of Societies.

### THE NON-EXCRETORY FUNCTIONS OF THE KIDNEY.

At a meeting of the Section of Medicine of the Royal Society of Medicine, held on April 24th, with the president, Dr. A. F. HURST, in the chair, Professor SNAPPER of Amsterdam read a paper on the non-excretory functions of the kidney and their clinical importance.

Professor Snapper said that the kidney was usually regarded as an organ of excretion, but if the energy used up by the kidney were calculated, although a large amount was required for producing the hyperosmotic urine, this did not account for all the energy consumed. It was customary to regard the liver as having an excretory function for bile, but as being mainly a gland having great metabolic importance. In the same way the kidney had an excretory function, but had also a metabolic function. He then pointed out the importance of the observations of Nash and Benedict, who showed that ammonia was formed in the kidneys of certain animals, a factor of great moment when large amounts of acid had to be excreted, for the process could continue effectively so long as the kidney function was unimpaired. In certain circumstances this function of the kidney was impaired and a condition of acidosis resulted which could be observed in uraemia. In diabetic acidosis also the impaired function of the kidney for ammonia formation interfered with the excretion of ketone bodies. The important point in diabetic conditions was, of course, the accumulation of ketone substances in the body fluids, and there were cases of diabetic ketosis in which the amount of ketone substances in the urine was only very slight, although a large ketonaemia was present. In such cases the ammonia content of the urine was hardly increased at all, and even after treatment with insulin such cases for a long time passed urine with diminished ammonia excretion. The ketonaemia in such cases must be regarded as partly due to the failure of the ammonia-forming function of the kidney. Dealing next with the excretory function of the kidney, Professor Snapper mentioned the well-known power the kidney possessed for the synthesis of hippuric acid when perfused with benzoic acid and glycecoll. Such synthesis had recently been confirmed as occurring in the human subject as a result of experiments on kidneys removed at operation, and it had also been shown that a similar synthesis took place for other acids of the benzoic series. Another non-excretory function of the kidney was its power of oxidation, and this had been shown experimentally to occur with the aromatic fatty acids. It had also been easy to show by perfusion experiments that beta-oxy-butyric acid and diacetic acid could be destroyed in large amounts by the kidney, and it was therefore important to consider whether in diabetic coma the condition was in any way due to an impairment of this oxidative function of the kidney. There were still cases of diabetic coma in which

treatment by insulin reduced the hyperglycaemia, the hyperketonaemia, and the ketonuria, and yet failed to save life. Most clinicians considered that such cases died of a failure of the circulatory system. The speaker was of the opinion that while these cardio-vascular factors were of great importance there were other factors, of which renal insufficiency was next in seriousness. It had been known for a long time that albuminuria was frequently present, especially in cases with ketonuria, and the older clinicians thought that there was some connexion between these two conditions. In diabetic coma it was often possible to find evidence of retention of urea and non-protein nitrogen in the blood, and uraemic coma was sometimes diagnosed erroneously. One possible reason for nitrogen retention was the oliguria which occurred in such cases, but this was not the only cause, for some had polyuria and still had nitrogen retention. The urine in these circumstances contained only small amounts of urea, and it was evident that the kidney function was impaired. It was possible to divide examples of diabetic coma into two groups. In one, in young subjects, owing to incorrect diet, there was a hyperproduction of ketone substances causing intoxication, even though the destruction of such substances was proceeding at a normal rate; these could be cured by insulin, which stopped the hyperproduction of these substances. In the other group degenerative changes had set in in the kidneys, and even a moderate production of ketone bodies led to intoxication. Insulin would remove the hyperproduction of ketone bodies in such cases, but the impaired kidney function led to death, for the destruction of these ketone bodies did not go on properly. There were pathological proofs of these changes in the kidneys, for at autopsy they could be found to be yellow from fatty degeneration, and microscopic examination revealed glycogen degeneration in the tubules and a special form of necrosis in certain of the tubules, especially in the descending limb of Henle's loop. Professor Snapper lastly dealt with the importance of these functions of the kidney in diabetic therapy, calling attention to the high fat diets used in certain countries, in which ketosis did not occur as long as the amount of protein was small. It was suggested that by relieving the load on the kidneys in these low protein diets the destruction of ketone bodies in large amounts could be carried out.

Dr. R. D. LAWRENCE said he thought those cases of diabetic coma which did not recover died from circulatory depression rather than from renal changes. He found casts and protein in the urine of every case of coma, and the prognosis did not appear to depend on this. He agreed that in cases with oliguria the prognosis was bad, but he thought this was probably due to low blood pressure rather than to renal insufficiency. He did not think that the addition of proteins to a high fat diet produced ketosis because of the added load on the kidney, but was more probably due to the production of fatty acids during the metabolism of the proteins.

Dr. E. P. POULTON said that nitrogen retention was almost a regular feature of diabetic coma. He thought that circulatory changes were of most importance in the death of those patients who did not respond to insulin. An important point in treatment of such cases was the giving of large quantities of fluid.

Professor FAHR (Minnesota) thought that the cause of death in those cases of diabetic coma which failed to respond to insulin was circulatory failure. He mentioned recent work in America and Germany which went to show that a condition resembling shock was present in such cases. Sir JOHN BROADBENT, Dr. P. J. CAMIDGE, and Dr. F. PARKES WEBER also took part in the discussion, and Professor SNAPPER replied to certain questions.

### POST-ENCEPHALITIS PROBLEMS.

At a meeting of the Section of Epidemiology of the Royal Society of Medicine on April 27th Dr. ALLAN C. PARSONS read a paper on post-encephalitis lethargica and its problems.

Dr. Parsons said that encephalitis lethargica was first recognized in this country ten years ago; while the etiology of the disease remained obscure there was more

knowledge now of its varied clinical manifestations, and certain facts concerning its epidemiology had been noted. The disease seemed to be relatively prevalent in these islands compared with other countries; diagnosis, treatment, and prognosis were difficult. Attention was now being chiefly focused upon post-encephalitis—the chronic phase of the disease which frequently follows the so-called acute attack; it was marked by various signs and symptoms which might either have persisted from the original illness, or might have supervened after the acute attack had apparently ended or had passed unrecognized. Upon the general population encephalitis lethargica, fortunately, made but small impact, and its incidence rate of 0.06 per thousand might be compared with that of 0.07 for enteric fever, and contrasted with rates of 2.10 and 1.45 for scarlet fever and pulmonary tuberculosis respectively. But, with the possible exception of cerebro-spinal fever, there was no disease which had, at the same time, so high a case-mortality rate and so high a case-disablement rate. In most of the fatal cases death occurred during the first three weeks of the primary illness, but it had become evident that in a not inconsiderable number it supervened at much longer intervals after onset. Thus of 452 death certificates received during 1926 in which the necessary particulars were given, 9.7 per cent. had recorded the death as occurring two years, 6.9 per cent. three years, and 2.6 per cent. six years after onset. It might be estimated that encephalitis lethargica eventually killed, or helped to kill, between 35 and 40 per cent. of those whom it was known to attack.

Consideration of various series of after-histories relating to patients notified in London, Glasgow, Belfast, Manchester, Bristol, Sheffield, and other large towns showed that a large proportion of patients did not completely recover from their primary illness, but suffered from sequels of varying severity. Thus of 1,173 patients notified in London during 1919–25, and whose cases were reviewed in 1926, 29.1 per cent. were found to be suffering from sequels; in 356 unnotified patients of the same series the sequel rate was 60.9 per cent. A review, after twelve months' interval, of the cases notified in the peak year of 1924 in London, Lancashire, Sheffield, Glasgow, Manchester, Belfast, and Newcastle-on-Tyne, showed that the sequel rates respectively for these local series of cases were: London 35.4, Lancashire 45.8, Sheffield 65.7, Glasgow 37.3, Manchester 50.7, Belfast 74.7, Newcastle-on-Tyne 34.3. The mean sequel rate in the case of 3,112 patients notified from these same cities over varying periods worked out at 41.9, and in rather more than half the number of patients the sequels were serious enough to prevent work or education.

The signs and symptoms of post-encephalitis were generally reminiscent of those which characterized the primary stage of the disease, and, with the important exception of Parkinsonism, as emphasized by Hall, it might be said that serious sequels were usually anticipated by severe symptoms in the initial illness; mental deterioration and conduct changes were also characteristic of the aftermath of encephalitis lethargica. By reason of their interesting variety the sequels of encephalitis invited classification as the primary symptoms of the disease had done, but for administrative purposes it was more useful to classify the post-encephalitis sufferers, rather than their symptoms, into three groups: (1) those who suffered mainly from physical sequels; (2) those who chiefly showed signs of mental deterioration; (3) those who exhibited demoralizations. This grouping was only loose, and a patient might partly qualify for two or more groups at the same time, or he might pass from one group to another at different stages of his post-encephalitic career. No physical sequel was so well known as Parkinsonism; indeed, so common and so important was this particular syndrome that by some it was regarded as almost synonymous with post-encephalitis lethargica. Roughly speaking, about half the patients who manifested after-effects developed Parkinsonism sooner or later; the latent period varied in most cases between three and eighteen months, but in a few instances this had been prolonged for two, three, and even five years. Unlike paralysis agitans, post-encephalitic Parkinsonism affected

males and females about equally and was by no means restricted to elderly subjects; the majority of sufferers, indeed, were under 30, and children were commonly affected. Isolated instances of recovery had been reported, but as a general rule the condition ended fatally, and accounted for most of the late deaths from encephalitis lethargica.

It was probably not too much to say that the mental processes of every subject of encephalitis lethargica were affected in some degree, either in the primary attack or subsequently, and the patients themselves fell easily into two classes—namely, those who were restless and excitable, and those who were dull and depressed. Typical of the irritable or positive type of mental disturbance (and almost pathognomonic of post-encephalitis) was the nocturnal restlessness associated with the inverted sleep rhythm which was so common in children. Positive symptoms of a more severe type were displayed by those older patients who were subject to maniacal outbursts or homicidal impulses. A different picture altogether was presented by the depressed or passive type of post-encephalitic patient. The backward child's inability to make any progress at school was due to a dulled intelligence, an impaired memory, and perhaps drowsiness, rather than to the restlessness, impatience, and lack of concentration which made teachers despair of the excitable type of child. Children in an advanced stage of Parkinsonism often provided examples of the passive type of case, but it was mainly adult patients who typically suffered from mental anergia. The mental disturbance in both the excitable and the depressed types might be severe enough eventually to justify certification; the excitable ones mainly for the sake of others, the passive ones mainly for their own protection. Up to the end of 1927 there had been admitted to mental hospitals and mental deficiency institutions 674 patients whose mental condition was caused by encephalitis lethargica. The subjects of demoralizations (Group III) were for the most part children and adolescents; through lack of inhibition they had become quite unmanageable at home, were given to lying and thieving, committed crimes against society, and found their way into reformatories or prisons. There was little or no intellectual impairment in the case of these children, though they often lacked the "capacity for mental comparison and discrimination"; they were morally defective, and exhibited startling changes, for the worse, in character.

The problems of post-encephalitis varied considerably according to the age of the patient. Released from the discipline and routine of hospital life, with a disposition strangely altered and with nocturnal restlessness as a prominent symptom, the young irritable child soon became an unmanageable nuisance; or, as the subject of Parkinsonism, he might be teased by thoughtless brothers and sisters, or scolded by impatient parents for a slowness of mind and body the significance of which was not understood. In either case the patient was out of place at home. In juveniles the question of education had to be considered, and, generally speaking, it was found that a return to their usual school was not practicable for children seriously handicapped by post-encephalitis. For some, the schools for backward children might provide the extra individual attention and patience required; unfortunately, however, the physical and mental consequences of the disease were so frequently accompanied by conduct changes that these children imposed an unjustifiable strain upon teachers, and might cause physical or moral harm to the other children. The resources of the Board of Education might then become exhausted, and it was in these circumstances, and for children with some prospects of improvement, that an encephalitis unit like that at Winchmore Hill—with its special arrangements for carrying on the child's education while under medical treatment and institutional discipline—seemed to meet a need. Industrial schools and reformatories had not, in the opinion of the Home Office, proved suitable repositories for the troublesome boy or girl. Of the 108 children admitted to these Home Office schools up to January 31st, 1927, 57 had been discharged, and of these 95 per cent. showed no improvement. Fresh difficulties arose when the youth, now over school age and

potentially more dangerous, was discharged from the Home Office school; he was more than ever unsuited for his home; he rarely gave satisfaction if placed out in employment; he might be tolerated for a time in a Poor Law institution if he consented to remain there; and, until the Mental Deficiency Act was amended at the end of 1927, it was seldom that such a case could be certified. Thus under the principal Act of 1913 it was not found possible to certify more than one-fifth of the juveniles under training in Home Office schools. Meanwhile, the ex-reformatory school inmate might come into more serious contact with the law, and as a result be placed in a Borstal institution, or he might be committed to prison. Borstal training had not apparently proved of much avail; but of the 72 post-encephalitic subjects who were admitted to prisons during the period April 1st, 1925, to March 31st, 1927, the Medical Commissioner reported that 54 "showed either no harmful effect from imprisonment or were definitely improved."

The adult post-encephalitic patient, suffering typically from physical infirmities or from mental anergia, was less prominent, though often presenting an anxious domestic problem. It might be the breadwinner who could not retain his old job, nor prove himself suitable for others, who then sat at home by the fire bemoaning his fate and becoming a burden on his family. Or it might be the wife, once the intelligent mainstay of the home, who had now become careless and lethargic, unmindful of her children and without any interest in her household duties. Such cases were not eligible for hospitals, nor were they welcomed in convalescent homes and such places. Eventually a certain number of these patients became certifiable, but a greater proportion found ultimate refuge in Poor Law institutions.

Further research into administrative methods was needed before it could be decided what were the best methods for dealing with these various types of post-encephalitis patient. For the present, it would seem that young subjects, under puberty, with slight psychic disturbance and whose general prospects were not hopeless, merited such institutional facilities as the Metropolitan Asylums Board had provided at Winchmore Hill; for many of the difficult adolescents the amended Mental Deficiency Act of 1927, it was hoped, would prove serviceable in securing for them adequate control and protection. That the lot of the uncertifiable adult could be lightened and his domestic anxieties relieved had been proved by the examples of Bristol, Glasgow, and other places, where, as the result of sympathetic co-operation between the various local departments concerned, special arrangements had been made for these patients in existing Poor Law institutions.

A MEETING of the Wolverhampton and District Clinical Club was held at the General Hospital, Wolverhampton, on April 17th. Dr. G. S. ASTON demonstrated clinically an instance of bilateral Charcot's joints, affecting the knees, in a patient with tabes dorsalis. Mr. S. MASLEN JONES described a case of hydramnios associated with uniovular twins, and criticized several theories accounting for the great excess of liquor amnii in this condition. Dr. W. R. SOMERSET exhibited the inhaler for closed ether anaesthesia which he has invented, and described various methods of using it. He emphasized the benefit of starting anaesthesia with ethyl chloride before passing on to full ether.

THE *Eugenics Review*, published for the Eugenics Society, has hitherto been circulated among members of that body only, but it has now been decided, in order to meet the growing interest which is believed to exist, to make the *Review* available to a wider public by placing it on sale in the ordinary way. For the April issue—the first to appear under the new regime—a more attractive format has been adopted. Among the contents is an extended report of the 1928 Galton Lecture on "Causes of Racial Decay" by Mr. C. J. Bond, of which a summary was published in our issue of February 25th (p. 315). A noteworthy feature, particularly of the editorial notes and book reviews, is the lively, not to say provocative, manner in which the various contributors deal with their subjects.

## Reviews.

### "TAYLOR'S MEDICAL JURISPRUDENCE."

IN preparing an eighth edition of *Taylor's Principles of Medical Jurisprudence* the publishers have very wisely submitted the work of revision to well-known authorities in both the medical and legal professions. A medical man, even though possessing extensive court experience and perhaps a law qualification, is bound to regard the subject from the medical aspect, and the advantage of having the legal viewpoint incorporated in this premier work cannot be overestimated. Especially is this the case in the present edition.

Professor SYDNEY SMITH is one of the few men who have devoted themselves entirely to the study of forensic medicine; he has enjoyed unrivalled opportunities for forensic practice in Egypt, where until recently he was the principal medico-legal adviser to the Egyptian Government. Together with Mr. W. G. H. COOK of the Middle Temple he has not only brought Dr. Taylor's famous work up to date, but has restored to it a great deal of the personal touch which is so apt to be lost when a book passes through the hands of a long succession of editors. Very much of the work is, of course, unchanged. We would have liked to see Professor Smith break away from the custom of previous editions, and include a description of the powers and functions of the General Medical Council and of the relations of the doctor to the State. A textbook of medical jurisprudence is perhaps the only place in medical literature which is suitable for a description and discussion of the legal obligations, penalties, and control to which a medical man submits himself when he places his name on the *Medical Register*, and we hope that an adequate account of this important matter will be included in the next edition.

Like other subjects in medicine, medical jurisprudence is growing, and its offshoots are tending to outgrow the parent. As in previous editions, much space has been devoted to insurance and workmen's compensation. These subjects have now grown to such an extent that they possess a literature of their own, and the question arises whether they should not be omitted from a book on medical jurisprudence. The subject cannot be dealt with thoroughly even in a work of these dimensions, and when "Taylor" ceases to be the authority on any question it indicates that, like public health, the subject has become a study on its own.

Professor Sydney Smith has made a special study of firearms, their identification, and the injuries they produce. His large experience of such cases has made him one of the chief authorities on this subject, and, as we should expect, the section dealing with gunshot wounds contains much fresh material. The other sections, especially that on identity, have likewise been stamped with the mark of personal experience. In the toxicological part of the work the description of gas poisoning, which has come into such prominence lately, has been thoroughly revised. This part of the book in general is well up to date. The legal aspect has been dealt with in an equally thorough manner, and in a way which gives the reader confidence in the legal views expressed. A reference to tetra-ethyl lead in motor fuel appears, though the recorded symptoms of industrial poisoning by this means are no doubt too recent to allow of a full description.

*Taylor's Medical Jurisprudence* needs no introduction or commendation: it is an essential book for any medical man to consult before appearing in a court of law. This new edition shows many improvements, though there are parts, notably in the description of the course to be adopted by medical men in cases of doubtful natural death, where a definite line of action would be preferable to a discussion. The additions and improvements in this eighth edition render it indispensable as a work of reference to anyone engaged in the practice of forensic medicine, and

<sup>1</sup> *Taylor's Principles and Practice of Medical Jurisprudence*. Edited by Sydney Smith, M.D., D.P.H. Eighth edition. With a complete revision of the legal aspect by W. G. H. Cook, LL.D., London: J. and A. Churchill, 1928. (Roy. 8vo, Vol. 1, pp. viii + 400, 39 figures; Vol. II, pp. v + 564, 4 figures, 63s. net.)

the editors are to be congratulated on the very successful manner in which they have completed a difficult task. To those who have a deep interest in the subject the happy thought of prefacing the book with a portrait of the great Taylor will be especially welcome.

### ANIMAL ORGANISMS AND THEIR ENVIRONMENT.

Man may have greater control over his environment than other animals, but he must remain one of the whole system of living things; it is impossible for him to avoid his relations with other beings and to remain cloistered in his own walls. Oecology (or ecology) is defined in the *Oxford English Dictionary* as "the science of the economy of animals and plants; that branch of biology which deals with the relations of living organisms to their surroundings, their habits, and modes of life, etc." A new science cannot arise or progress without stimulation. The scientific study of animal ecology is yet in its early stages, but in Mr. CHARLES ELTON'S book on this subject we find an accurately placed milestone of progress and encouraging views of lines for future advances. To many who read it the fascination of the subject may lie in its multitudinous ramifications, and its dependence on other, and not necessarily closely allied, sciences; others will find their interest in living creatures stimulated and perhaps, crystallized. All must admire the competence of the author and the clear way in which a complicated subject is so easily handled, so much so that at times one is tempted, as many of the pioneers in this field were tempted, to overlook the intricacy of the facts and the analysis of themselves. But the relevancy of the facts and the analysis of their implications are so astutely developed that the end-result of the treatment leaves no doubt as to its value.

The sequence of chapters is logically preserved, and the introductory synopses of each add greatly to the convenience of the reader. Those dealing with the numbers of animals and the variations in numbers should appeal strongly to the general reader, whose interests are also well provided for in the very representative bibliography; the discussion of "Methods" (chapter xi) has many morals of wide application, besides being of peculiar worth to the ecologist. Professor JULIAN HUXLEY is to be congratulated on this volume of the series of textbooks on animal biology which he edits—his introduction provides much food for thought—and Mr. Elton well deserves our thanks for his distinctive treatise.

### STRABISMUS.

In a large and profusely illustrated monograph entitled *Strabismus* Dr. OSCAR WILKINSON of Washington has treated the subject of squint in considerable detail. The moral running through the book is the importance of early treatment and the tragedy of allowing a cross-eyed child to grow up neglected until he arrives at an age when his deformity is incurable.

The book opens with an historical chapter full of interesting anecdotes dating from the time of Hippocrates. Then follow a summary of the various theories regarding the etiology of squints and a discussion of the anatomy and physiology of the ocular muscles and the physiology of vision. The various types of squint are then described; it is rather disconcerting to learn that there are forty-four of these. The clinical methods authorized in the detection and measurement of squint are clearly detailed, and the various methods used in the clinical investigation of the cases. The chapters dealing with the treatment of orthoptic cases are well written; much stress is laid upon orthoptic methods, the training of binocular vision, and the practice of the stereoscope. Many operative procedures are also described, including tenotomy, advancement, and recession. Precision in the extent of operative correction is insisted upon, but at the same time it is rightly pointed out that operation by itself merely gives a cosmetic result and does

not bring about a cure; there is only a mechanical relief of the deformity with the functional loss of the eye. Dr. Wilkinson's book is well written and beautifully produced. The beauty of its production, indeed, is its main drawback, for, considering the extent and scope of the subject matter, this has made its cost almost prohibitive.

### EXPERIMENTAL RICKETS:

*Experimental Rickets* is clearly a work to which the author, Dr. POUL FREUDENTHAL, has devoted a very large amount of labour. He has gone at great length into the literature of the subject, and describes a considerable mass of experimental work. There are, however, now so many monographs on medical subjects that addition to their number seems to need justification. Such justification could be offered for a work which presented new and important facts, which reviewed past and current literature in a convenient manner, or which furnished a compact and comprehensive survey of a wide field. Unfortunately we do not feel that the present volume fulfils these conditions. Of some 230 pages, 49 are devoted to an historical review, some 70 to the author's own experiments, and 71 to photomicrographs and diagrams. The remainder are distributed between "The pathogeny of A-avitaminosis," "Conclusion," "Summary," and a discussion of the importance of the conclusions reached the treatment of rickets. The historical review is extensive, but so badly arranged that it is impossible to distinguish important from unimportant findings. The author's discussion of his own results would be more convincing were it more sharply defined, instead of being intimately mixed with his views on the findings of others which should, one feels, have found a place in historical survey. The reader receives the impression that the author is unwilling to admit the existence of a rickets vitamin, as distinct from vitamin A, and it is quite clear how far he believes in the antirachitic value of ultra-violet light. While no sensible person will claim the existence of vitamin D, or its relationship to the existence of no discussion, yet both are supported by considerable weight of evidence. If the present position be challenged, it can only be attacked on the strong and direct evidence, and such evidence failed to discover in Dr. Freudenthal's book.

### MARIE'S COLLECTED PAPERS.

REFERENCE has already been made in our column volume, published in 1926, entitled *Travaux et* by Professor PIERRE MARIE, dealing with aph megaly, achondroplasia, and other affections of the A second volume has now appeared, and contains reprints of a number of papers which have been published from time to time to various periods of Professor Marie's career. The collection of original accounts of diseases which are described by him, or are intimately associated with his name, is divided into two main sections: in the first, prominence is given to three of the more important articles—namely, those on the Charcot-Marie form of "lacunae"; on hereditary cerebellar ataxy, and on cerebral "lacunae"; the second part contains articles on diverse diseases of the central nervous system, to which are appended several papers on various subjects, such as Graves's disease and skeletal deformities occurring in nervous affections. The article on the Charcot-Marie amyotrophy is that in which Marie separated off the disease as a distinct entity from other forms of progressive muscular atrophy. The same disease was subsequently described under the name of the peroneal type of muscular atrophy by Tooth, and by Hoffmann as neurotic muscular atrophy. The second article contains the original description of the then (1893) new clinical entity to which Marie gave the name of hereditary cerebellar ataxy, a condition related to Friedreich's ataxy.

\* *Experimental Rickets*. By Poul Freudenthal. Copenhagen: Levin and Munksgaard, 1927. (Sup. roy. 8vo, pp. 235; illustrated.)  
 \* *Travaux et Mémoires*. Par Pierre Marie. Tome deuxième. Paris: Masson et Cie, 1928. (Med. 8vo, pp. 393; 48 figures, 2 plates. 30 fr. 50 majoration.)

\* *Animal Ecology*. By Charles Elton, with an introduction by Julian S. Huxley, M.A. Textbooks of Animal Biology. London: Sidgwick and Jackson, Ltd., 1927. (Demy 8vo, pp. x + 207; 13 figures. 10s. 6d.)  
 \* *Strabismus*. By Oscar Wilkinson, A.M., M.D., D.Sc. London: H. Kimpton, 1928. (7 x 10, pp. 240; 120 figures. 42s. net.)

through transitional forms. The article on cerebral "lacunae" was the outcome of an observation of the relative infrequency of haemorrhages and softening in the brains of old hemiplegics, which Marie had special opportunities of observing. He found that in the majority of cases the lesions had the form of a number of spaces or lacunae, varying from the size of a millet seed to that of a bean, and situated in or near the grey centres or in the pons. He held the lacunae to be due to softening and degeneration, and the constant coexistence of arteriosclerosis suggested that this was a sufficient explanation; in some instances, however, the arteries in the feet were freely permeable, and Marie suggested, as a possible alternative explanation, that the softening resulted from an inflammation of the perivascular sheath, which was in all cases found to be considerably dilated. Post-mortem emphysema was definitely excluded. The present volume, like its predecessors, is full of interesting matter.

#### ANALYSIS OF THE FAECES.

DR. RENÉ GAULTIER has filled a gap in the long series of laboratory textbooks by his description of the clinical analysis of the faeces,<sup>6</sup> a third edition of which has been published. He starts with a careful account of the nature of the several faecal constituents in health, and discusses the factors concerned in their production. He then gives details of the various investigations, both macroscopic and microscopic, emphasizing the procedures which determine the presence or absence of abnormalities. Special attention is given to the general physical characteristics, substances derived from the food or from the digestive processes, bacteriology, and parasitology. The subject of the appearance of the different forms of fat in the faeces is treated with particular care, the conditions regulating their occurrence being defined in order that their diagnostic value may be made evident. Numerous illustrations are supplied, but in an English mind the absence of an index is regrettable. The information is given clearly and well, and the various methods are fully explained. The author has achieved the rather difficult task of relating laboratory investigations to clinical conditions without permitting the book to exceed a reasonable size.

#### NOTES ON BOOKS.

THE fourteenth edition of *Green's Manual of Pathology and Morbid Anatomy*<sup>7</sup> has been revised and enlarged by Dr. A. PINEX. Very few alterations have been made, except in the sections on nephritis and surgical shock, and the book still retains the form with which so many generations of students have been familiar. The original edition appeared in 1871, and was one of the first systematic introductions to English students of the cellular pathology associated with the name of Virchow. Since the publication of the last edition five years ago Dr. Thomas Henry Green has died. He had been unable to take part in the preparation of new editions for several years, but the tradition he established has been worthily maintained by a succession of subsequent editors. It has always been a favourite book with students, and is likely to remain so.

The transactions<sup>8</sup> of the second session of the Australasian Medical Congress (British Medical Association), which was held at Dunedin, New Zealand, in February, 1927, have now been collected and published in volume form. A summary of the proceedings appeared in the five issues of the *British Medical Journal* dated March 26th to April 23rd, 1927 (at pp. 584, 622, 670, 738, and 773), so that those who may have been attracted by any point mentioned at that time will now be able to obtain the full text of the papers, together with the discussions which took place. It may be recalled that the first session of the Congress was held at Melbourne in November, 1923. At the more recent gathering in Dunedin the Association at home was represented by Dr. Cooper Pattin of Norwich. It would be superfluous to attempt to detail the ground covered in the meetings of the

twelve sections; the range of subjects was almost coextensive with the field of modern medical science. The president, Sir L. E. Barnett, in his address, dealt with medical ideals and by criticism, and in a special meeting a series of papers on preventive medicine, the relation of the private practitioner to the State and to the hospitals, and national insurance was given. Considerable general interest attaches to the popular lecture on "The coming of the Maori" by Dr. P. H. Buck (Te Rangi Hiroa), director of Maori hygiene. In format and typography the volume is excellently produced, and useful indexes to speakers and subjects have been provided. The illustrations deserve special mention; there are numerous reproductions of diagrams, drawings, photographs, and skiagrams, many on special plates, which add considerably to the value of the various papers, and give an additional distinction to an interesting volume.

In content and format the 1928 edition of *The Yearbook of the Universities of the Empire*<sup>9</sup> maintains the now familiar style of earlier issues, and although a few pages have been added the volume remains still of a convenient size for a work of reference. Within its covers are compressed the central facts relating to some seventy establishments of university standing, with staff directories, information relating to curricula, degrees, diplomas, fees, etc., and various other matters. A useful appendix contains a guide to professions and careers open to persons possessing university qualifications, and others embody particulars of research grants and centres of research outside universities. The indexes are notably well arranged.

<sup>9</sup> *The Yearbook of the Universities of the Empire, 1928.* Published for the Universities' Bureau of the British Empire, London: G. Bell and Sons, Ltd. 1928. (Cr. 8vo, pp. xiii + 856. 7s. 6d.)

#### PREPARATIONS AND APPLIANCES.

##### HYOSCINE HYDROBROMIDE.

For the convenience of medical practitioners who wish to prescribe full doses of hyoscine hydrobromide for oral administration Burroughs Wellcome and Co. now issue "tabloid" hyoscine hydrobromide, grain 1/100 (0.00065 grm) in bottles of 100. "Tabloid" hyoscine hydrobromide 0.0005 gram (grain 1/220 approximately) has been issued for many years, as have also several strengths and combinations for hypodermic use.

##### A SYRINGE FOR INJECTING VARICOSE VEINS.

In giving injections for the chemical sclerosis of varicose veins the ordinary "record" syringe of two or three cubic centimetres capacity, with very fine hypodermic needles, has been the instrument of choice amongst practitioners, though it has the following disadvantages.

(1) The needle of a "record" syringe is in direct line with the barrel, so that the latter, more particularly in the case of awkwardly situated veins, is apt to obscure the segment of the vessel to be injected.

(2) As a proof that the lumen of the vein has been entered a little blood must be aspirated along the needle into the syringe. This blood, by mingling with the sclerosing fluid in the barrel, fouls it for subsequent injections.

(3) The graduations found upon the "record" syringe are not particularly adapted to the technique.

In an effort to overcome these disadvantages Drs. Katherine Cellan-Jones and C. J. Cellan-Jones (North Shields) have recently had made a modification of the syringe produced by Katz some years ago, and after a test period of three months they are satisfied that this syringe is a most useful and reliable instrument.

As shown by the accompanying illustration the syringe has a

glass barrel and piston, the former graduated in capacities of one-quarter of a cubic centimetre, the latter coloured dark blue for convenience in gauging the amount of a colourless fluid which is to be injected. The lower end of the barrel passes into a glass capillary tube bent upon itself and possessing, towards its extremity, two small dilated chambers. A white opaque background has been introduced in the length of the capillary in order to render the appearance of a minute column of blood more easily visible. The metal nozzle of the syringe, which snugly fits all sizes, and makes of hypodermic needles, has the same coefficient of expansion as glass, thus readily allowing of sterilization by boiling. A metal safety catch situated beyond the graduations fits lightly into a groove upon the piston, and prevents the latter from falling accidentally from the barrel.

When a vein is entered blood can be aspirated along the capillary tube into the ampullae, and when subsequently an injection is made the blood is forced back into the vein, leaving the remaining fluid in the barrel clear and untinted. In this way six or more injections may be conveniently administered without having to change or wash out the syringe.

This instrument has been manufactured for Drs. Cellan-Jones by Braun and Co. of Melsungen, Germany; the London agents are Adair Duff and Co., 47, Victoria Street, S.W.1.

SATURDAY, MAY 5TH, 1928.

## BRITISH LARYNGOLOGY.

THE invitation extended to Sir StClair Thomson by the president of the American Laryngological Association—the most exclusive body of its kind in any country—to give the address of honour on the fiftieth anniversary of its foundation, is a pleasant reminder of the cordial relations existing between the medical profession in the United States and in Great Britain.

The address itself, which may be found in full in the opening pages of our present issue, deals with the treatment of intrinsic cancer of the larynx by the operation of laryngo-fissure, a subject which the orator, by teaching, demonstration, and research, has made peculiarly his own. He is now able to trace the fate of seventy patients subjected to this method of treatment, a record which is unequalled either in point of numbers or in results. There is little likelihood that it will ever be equalled in numbers, for intrinsic laryngeal cancer is a relatively uncommon disease, and there are now so many competent followers of Sir StClair Thomson's teaching and technique that cases suitable for this operation will doubtless in future be distributed between numerous well-trained operators. It is more profitable to inquire whether the results are likely to be equalled or surpassed. Sir StClair Thomson admits an immediate death rate of 4 per cent.—that is, three post-operative deaths in seventy cases—yet if the case-histories of these three patients are carefully studied it will be noticed that in all of them death was only indirectly due to the operation. The full and accurate record demands a technical mortality of 4 per cent. Here, as often, the statistics prove a *mensonge en chiffres*, for the direct mortality of the operation has in reality been nil. There is therefore no challenge to be feared in this respect.

Of all the 70 patients thus treated, 34 are now alive, and of these 32 have survived from three to nineteen years from the date of operation without recurrence; 18 patients have died from other causes without recurrence, 7 have died from malignant disease elsewhere, and 11 have died from local recurrence. The record must be studied in detail to appreciate the real significance of these figures, which give 76 per cent. of lasting cures. The pioneer work on this truly conservative operation was performed by Butlin and Semon in this country, but there was no finality about it, for in some respects they left it in an unsatisfactory state; and so here again, without in any way detracting from the merits of what has already been accomplished, it may be that, based on the experience gained and faithfully recorded in these seventy cases, this 76 per cent. of lasting cures may be raised still higher. Brilliant as it is for any series of cases of malignant disease, and making allowance for certain favourable peculiarities about cancer in this part of the body, it is yet possible that the knowledge gained by the study of Sir StClair Thomson's seventy cases will enable laryngologists to make an even better selection of cases for this operation, and so raise the percentage of lasting cures. Each of these cases,

however, has been studied so carefully and exhaustively, and the operative results have been so good, that it really seems as though there is but little more to be done in this particular direction.

The paper by Sir Charles Ballance and Mr. Lionel Colledge, which also appears in this issue of the *British Medical Journal*, brings to a definite conclusion a certain line of investigation into the possibility of treating laryngeal paralysis by means of nerve anastomosis. The earlier stages of this experiment will be familiar to many of our readers, for they have been recorded in these columns. A bilateral anastomosis between the phrenic and cut recurrent laryngeal nerves in a monkey resulted in complete restoration of synchronous movements to the vocal cords, and the animal was kept for three years, the result being confirmed by repeated examinations before Dr. Harvey Cushing and the late Sir David Ferrier and Sir Frederick Mott, among others. The animal has now been killed, and microscopic examination of the larynx shows complete recovery of the muscles and nerves concerned. Proof of the functional success of this experiment is thus confirmed by histological examination, and, further, it has been possible, as the direct result of experimental work, to apply the method to the relief of symptoms caused by bilateral abductor paralysis of the larynx in a human being.

These two papers, the one recording a purely clinical research, the other almost entirely confined to a laboratory investigation, show that British laryngology is well able to maintain its position. They should be an encouragement to the younger laryngologists in this country to carry on the torch.

## PURE MILK PROGRESS.

Much energy and ingenuity have been spent in recent years in the attempt to improve the purity of the milk supply of this country. It is satisfactory to learn from an article by Dr. R. Stenhouse Williams, research professor in dairy bacteriology in the University of Reading, and Mr. W. A. Hoy of the same university, printed in the *Journal of State Medicine*,<sup>1</sup> that in their opinion substantial progress has already been made. From a series of tables dealing with the milk supply of various large towns and of large distributing agencies these research workers show that the number of farmers producing milk with low bacterial content has increased very largely during the past five or six years. Thus with one firm in Birmingham the number of farmers supplying milk containing on an average fewer than 10,000 bacteria per cubic centimetre was only 2 in 1922 and as many as 69 in 1926. Between April and August, 1927, one firm in the Midlands supplied milk which consistently gave a count of below 200,000 per cubic centimetre on arrival in London, and several other farms in the same area had nearly as good a record. A very large number of samples in various districts stood the *Bacillus coli* test, though an examination of the tables published shows that it is more difficult to eliminate coliform organisms than to reduce the count.

Professor Stenhouse Williams and his fellow workers in the National Institute for Research in Dairying at Reading are impressed by the excellence of the work of which the milk industry is now capable. He calls attention to the encorniums, in a recent issue of the *Journal of the American Medical Association*, on Great Britain's long list of large cities free from a single

<sup>1</sup> *Journal of State Medicine*, vol. xxxvi, No. 2.

death from typhoid fever; and he attributes the improvement in the purity of the milk supply in this country to two stimuli—wise advice concerning proper methods of handling milk, and a financial stimulus. He finds that the object has been furthered by county clean milk competitions, which were originally started in Essex by the Howards Dairies; by the advisory bacteriological posts set up under the auspices of the Ministry of Agriculture in provincial centres; by the Ministry of Health's system of granting licences to those who wish to produce a better quality of milk; and by the educational facilities now provided and increasingly made use of at such places as the Chelsea Polytechnic. Through these means very remarkable work is being accomplished, even by tenant dairy farmers who do not possess adequate chilling facilities for use during the summer months.

Owing to the difficulty now experienced by farmers in obtaining skilled milkers, two other research workers at Reading University, Mr. A. T. R. Mattick and Mr. F. Proctor, have been investigating the production of milk of low bacterial content by means of milking machines. The difficulty with this method of milking has been to keep the parts of the apparatus clean; so that, as with the old-fashioned domestic water filter, more germs were liable to come out at the exit than entered at the inlet. The observers used for their experiments, which are described in a recent issue of the *Journal of Hygiene*,<sup>2</sup> two units of an Alfa-Laval milking machine, one of which was washed with water, first cold and then at 185° F., while the other, after preliminary washing, was sterilized by steam. It was found that extraordinary fluctuations occurred in bacterial counts, whether the apparatus was sterilized or merely washed. Investigation showed that the contamination took place from water in the vacuum pipe line, from which bacteria found their way into the milk receivers, although a check valve was provided in the lids. By adopting a simple method of traps to the pipe line, and turning all vacuum supply taps upwards, the observers were able to obtain remarkably low bacterial counts in milk, especially with the sterilized unit, even twenty-eight hours after milking. They are convinced that milk with small bacterial content and of good keeping quality can be produced by the use of milking machines; that the milking units and their rubber components can be sterilized successfully by steam; and that contamination from pipe lines can easily be prevented by their methods. They found also that milking machines had no adverse effects on the cows or on their milk yield.

Thus the dairying industry, as Professor Stenhouse Williams remarks, has made great strides since the days when a few people like Mr. Wilfred Buckley were producing clean milk and creating their own markets without official support. On the one hand, there is an increasing desire to make use of scientific knowledge, not only among large firms, but in many much smaller businesses; on the other hand, there is the growing recognition that better work is worth more money. These two factors, operating side by side, have caused a marked improvement in the cleanliness of our milk. Continued collaboration between farmers and dealers, working in close touch with those who are studying their problems in the laboratory, should lead to further progress all along the line. As knowledge increases we may expect the high standard of efficiency already reached by the licensed milk producers in forward areas like Reading to be attained throughout the country at large.

<sup>2</sup>*Journal of Hygiene*, vol. xxxvii, No. 2.

# AN INTERNATIONAL COMMITTEE FOR RESEARCH ON INFANTILE PARALYSIS.

AN international committee for the study of infantile paralysis has recently been formed under the chairmanship of Dr. W. H. Park, director of the Bureau of Laboratories of the New York City Health Department. Arrangements have been made for a concerted three-year attack on the difficult problems of prevention and therapy presented by this formidable and crippling disease. To enable research to be conducted at a number of centres in the United States and in Europe, a sum of 250,000 dollars has been contributed by Mr. Jeremiah Milbank, a prominent New York financier who takes an active personal interest in hospitals and charities. The following centres have been chosen for the proposed researches: Bureau of Laboratories, New York City Health Department; the pathological institutes of Columbia, Harvard, and Chicago Universities; the Pasteur Institute, Brussels; and the Lister Institute, London. These various institutes are represented on the international committee by their respective heads. The personnel of the committee is as follows: Chairman, Dr. W. H. Park; vice-chairman, Dr. Joseph A. Blake (New York); Drs. E. O. Jordan and Ludvig Hektoen of Chicago University; Drs. F. P. Gay and Frederick Tilney of the College of Physicians and Surgeons, Columbia University; Drs. Milton J. Rosenau and Hans Zinsser of Harvard University; Dr. Lee K. Frankel of the Metropolitan Life Insurance Company; Sir Charles J. Martin of the Lister Institute, London; and Dr. Jules Bordet of the Pasteur Institute, Brussels. Mr. Samuel M. Greer and Dr. Josephine N. Neal will act respectively as treasurer and secretary, and the committee's headquarters will be Dr. Park's office at the Bureau of Laboratories, East 16th Street, New York. Directors of research at each selected centre will be free to initiate such investigations as seem to them desirable and within the compass of their respective institutions. The results of such researches will, however, be studied and co-ordinated by the international committee, and will thus constitute a joint piece of work. At the Lister Institute special arrangements are being made for research on poliomyelitis under the direction of Professor J. C. G. Ledingham. It would be difficult to overestimate the importance of this venture. In no field is new knowledge more urgently desired than in that of the neurotropic viruses, but the necessity of employing monkeys for the experimental study has impeded progress by reason of the heavy cost involved. It is nearly twenty years since Landsteiner showed that the virus of poliomyelitis could be transmitted to monkeys, but the little knowledge since gained of this and other neurotropic viruses has not materially clarified the preventive and therapeutic outlook. The present time is very favourable for a new attack on the problem. The last decade has witnessed very considerable developments in our knowledge of virus diseases, and methods of attack which have proved of promise in the investigation of certain other viruses may well be exploited in that of poliomyelitis. The generosity of Mr. Jeremiah Milbank in making the new venture possible will be widely appreciated.

## ARTIFICIAL HUMIDITY IN COTTON CLOTH FACTORIES.

THE effect of artificial humidity on the health of cotton weavers has been a controversial question between employers and employed for rather over fifty years, so that on the introduction of the Factory Bill of 1925, which contained clauses dealing in some degree with this matter, it was considered opportune to have a conference of both sides under Home Office auspices with a view to final settlement of the differences. Although the operatives still insisted upon total abolition of artificial humidity, and the employers claimed not only that such action could not be justified,

but that it would destroy an important branch of the industry, both parties were able to agree that a Departmental Committee would be a suitable body to decide the questions at issue. The committee was set up immediately, and on the scientific side included Professor Leonard Hill, Mr. F. T. Peirce of the British Cotton Industry Research Association, and Mr. D. R. Wilson of the Industrial Research Board. The report<sup>1</sup> has now been issued, and should, on the whole, give satisfaction. To cover the points of inquiry agreed upon by the conference, investigation was made on (1) the extent of mortality and sickness among weavers in selected areas, (2) the effect of total abolition on trade, (3) the extent of foreign competition and restrictions against humidity in other countries, (4) whether improved sizing could replace humidity, (5) the effect of humidity on fatigue and productive efficiency, and (6) the effect of air movement in reducing discomfort. The obtaining of reliable information respecting the health of weavers in both sections of the industry was necessarily regarded as the keystone of the inquiry. The requisite mortality figures for males for the period 1921-22-23 were obtained from the Registrar-General, and though these are not given in the report they are presumably similar to those published elsewhere.<sup>2</sup> They are distinctly against the humid shed, but, acting on the views expressed by such eminent witnesses as Dr. T. H. G. Stevenson, Professor M. Greenwood, Dr. Daley, and Dr. A. B. Hill, the committee is of opinion that the figures are too small to admit of any definite conclusion being formed. The duty of obtaining morbidity statistics was delegated to the Industrial Fatigue Research Board, the report, drawn up by Dr. A. Bradford Hill, being reviewed in these columns on January 14th last (p. 65). The committee expresses agreement with the findings, which were to the effect that there is no evidence that employment in humid sheds gives rise to more sickness than employment in non-humid sheds. Bearing in mind the mortality returns (so far as they are helpful) and the evidence of Sir Thomas Legge and others, it is concluded that one class of shed is no more dangerous to health than the other. Regarding the effect of humidity and of sizing on the tensile strength and extension properties of cotton, Mr. Peirce, a member of the committee, produced evidence which should convince the most conservative employer that he need not go beyond reasonable limits of temperature and humidity to weave his cloth effectively. It appears that humidity has much more effect on cotton yarn than has temperature; it increases the strength and extensibility markedly up to a limit of 80 per cent., but at a less rate over this; short staple cotton seems to be the most sensitive to humidity. The sizing of yarn is regarded as effective for its purpose, but the suggestion that it could be sufficiently improved to serve as a substitute for humidity is strongly negatived. It is therefore agreed that, whilst humidity is essential for the production of certain classes of cloth, the abuse of this agent could be further regulated with advantage. That foreign countries are competitors, and do not so far regulate the use of humidity, is agreed. Mr. S. Wyatt, who gave evidence, has previously shown in a report to the Industrial Fatigue Research Board that excessive humidity does produce fatigue and diminishes efficiency, and as a result of later experiments, carried out for the committee, he has found that the highest output was obtained at a dry bulb temperature of 72½° to 75°, and with a relative humidity of 75 to 80 per cent. Reference is also made to this observer's investigations on production of effective inside air movement by having paddles attached to the

shafting. The use of these is recommended for improving working conditions when the temperature becomes excessive, as in summer time, the assurance being given that air movement has no detrimental effect on the yarn. Alterations and additions to the regulations are recommended: the words "humid shed" to be replaced by "weaving shed," thus abolishing the present distinction, and power given to the Chief Inspector to grant relief to sheds where conditions are satisfactory; artificial humidification to cease at 72½° wet bulb, instead of 75°; weavers to cease work and leave the shed if wet bulb temperature exceeds 80°; the minimum dry bulb temperature to be 50° for the first half-hour of the day and 55° for the rest of the day; plans for conversions or new sheds to be submitted by the local authority to the superintending inspector of factories before sanction; provision to be made for continuing ventilation during the meal time and after work is finished; suitable cloakrooms to be provided for all sheds; air intakes for ventilators to be better designed and placed. Acting on the evidence of Professor Leonard Hill and Dr. Vernon, it was not considered advisable to adopt a "kata" standard for the sheds.

#### MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.

A MEETING of the Council of the Medical Women's International Association was held at Bologna on April 11th, and was followed on April 12th, 13th, and 14th by an open meeting, at which papers were read on medical measures for the protection of children and young persons in the various countries, and on diseases of the eye in relation to general medicine. There was an attendance of some 120 medical women representing fourteen different countries, and papers were also received from eight other countries which were unable to send delegates. Spain and Sweden, which have quite recently formed affiliated associations, sent fully accredited delegates for the first time, and Japan, where there are over 1,000 medical women, contributed a specially printed paper in German on the protection of children. The meetings were held in the old anatomical theatre of the "Archiginnasio," which has been preserved as a historical monument for the last hundred years, since the transfer of the University to newer buildings. It dates from the sixteenth century, and is entirely panelled in cedarwood, while the rostrum, from which the papers were read, is supported by two carved anatomical figures. At the further end is the grille, behind which the inquisitor watched proceedings in the seventeenth century. The local committee, in co-operation with the municipal and central authorities, had made the most generous and extensive arrangements for social entertainment and for visiting the various hospitals, including the famous orthopaedic institute, the Istituto Rizzoli. The Queen of Italy had consented to give her name as patroness of the conference, and a "committee of honour" had been formed with Signor Mussolini as honorary president and Signor Turati, secretary-general of the Fascio, as vice-president. An impressive inaugural ceremony was held in the library of the old University, at which speeches were made by the prefect, representing the Italian Government, the podesta of Bologna, and Professor Viola, president of the Faculty of Medicine. Lady Barrett, president of the Medical Women's International Association, replied. An afternoon reception was given by the podesta and the municipal authorities in the fine old town hall, which was decorated with the flags of all the nations, and on the evening of April 13th a dinner for 200 people, followed by a concert, was given at the Fascist headquarters of Bologna by the women's section. It was attended by all the foremost personalities of the town and University of Bologna, speeches being made by the prefect, the vice-podesta, Dr. Carepino Ferrari, president of the Italian

<sup>1</sup> Report of the Departmental Committee on Artificial Humidity in Cotton Cloth Factories, with Appendices. London: H.M. Stationery Office, 1928. 1s. 3d. net.

<sup>2</sup> Registrar-General's Decennial Supplement, 1921, Part II, pp. lxxvii and 115.

Association, and Dr. Lea Giorgi, chairman of the local committee. Miss Martindale replied on behalf of the Medical Women's International Association. Receptions were also given by the local committee of medical women, and by the officers of the International Association (Lady Barrett, Dr. Jane Walker, and Miss Martindale), at the Hotel Brini. A notable and most enjoyable week closed with expeditions to Ravenna and Rimini, where the municipal and medical authorities gave a hospitable welcome. At Ravenna lunch was provided in tents in the famous pinewood of Dante, and speeches were made, both in Latin and Italian, by the prefect and others. At Rimini the chief medical officer of health and other local doctors met the medical women at the station, and, after a reception at the town hall, they were conducted over the large children's convalescent home which lies by the sea. All who attended the international meeting came away with grateful memories of the hospitality of the Italians and admiration for their powers of organization on a large scale.

### SEA-SICKNESS.

SEA-SICKNESS, its causes and treatment, is a subject of perennial interest. Its symptoms are only too well known to the victims, though they are difficult to describe accurately to those who have never experienced them. Their explanation is by no means simple. We print on page 752 a short article by Dr. R. Allan Bennett which sums up in a convenient way a good deal of experience in this matter, which is one of real importance; for the condition may make a voyage a misery, and with the great majority of travellers by sea materially detracts from the pleasures of anticipation. The cause of sea-sickness is certainly not merely fear or anticipation, though these may greatly increase the liability. With a moderate ocean swell the milder symptoms may be experienced in mid-voyage by one who has till then been so happy that he is not even thinking about their possibility. The undue celebration of farewell by the medium of meat and drink is clearly inadvisable, but Dr. Bennett's 88 per cent. of patients who had over-eaten either before or during the voyage does not seem to differ significantly from the percentage of the ordinary non-suffering population at sea or ashore who do the same thing. As regards prevention, the avoidance of constipation and the cultivation of confidence appear to be the chief things necessary. The latter may be aided by the preliminary swallowing of a capsule or by any weird device in which the individual believes. Cross-channel passengers have been known to assert that they have avoided all discomfort by keeping one eye closed throughout the passage, or by the continuous eating of apples. A prophylactic mixture containing bromide and chloral with aromatics, sometimes appears to be of real help to the nervous passenger on the longer cross-channel trips, and chloretone has helped others, though its after-effects may be disagreeable, as is true also of some of the much-vaunted proprietary remedies sold at fancy prices. In longer voyages the consensus of opinion among stewards and stewardesses, if there be such consensus (for we understand that nowadays the ship's doctor is not usually consulted), may not be a bad guide to treatment. This, added to personal experience, tends to suggest that the horizontal position and fresh air are the two main requirements. The former is best secured in one's cabin, the latter on deck. This necessitates a nice adjustment of the balance of advantage. Dr. Bennett's dictum, that "however cruel it may seem, patients should be driven out of their cabins into the fresh air," will not be universally accepted. In the less severe cases, and with moderate weather, it is no doubt true, and should be acted upon; but in the presence of severe symptoms and weather there may be much to be said in favour of no attempt to get up. Moreover, if one has to suffer, it is usually preferable to suffer in seclusion. If

musea be very great one or two moderate doses of champagne often give most relief, or, as a second best and if the idea be not too revolting, dry ginger ale. Beyond these things, as a rule, there remains no resource other than an appeal to an unfeeling captain for a judicious choice of weather.

### THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

THE programme of the fourteenth triennial session of the Congress of American Physicians and Surgeons, which was held at the beginning of this week at Washington, D.C., has just reached us. This assembly differs in its constitution from any gathering of medical men with which we are familiar in this country, for it consists of fifteen constituent associations and societies, which hold their annual meetings every third year simultaneously and in one place, and devote the time of two meetings of the Congress as a whole to the discussion of subjects of general interest to all the fifteen component parts. In fact, the Congress resembles an Annual Meeting of the British Medical Association, but differs from it in the fact that except for two days in three years each of the sections leads an independent life. The programme is a very full one, and after looking through it we are not surprised to find that a proposal is to be brought forward at the request of the American Pediatric and the American Gynecological Societies to make the meetings of the Congress quinquennial in future. The amount of correspondence and discussion necessary to arrange such a programme may well require a longer interval for recuperation than three years. The membership of the component associations includes many Canadians, whose contributions to the programme show that they are by no means inactive. Certain European physicians and surgeons also appear among the readers of papers. Dr. J. W. Kernohan of Belfast spoke (by invitation) on encephalitis periaxialis diffusa before the American Neurological Association, and Mr. Harry Platt of Manchester read a paper on peripheral nerve complications of certain fractures before the American Orthopaedic Association—a subject full of interest just now when the treatment of fractures is so much discussed. Sir St. Clair Thomson contributed the address on laryngo-fissure for cancer which appears in our present issue and is discussed in a leading article, and Dr. S. A. Kinnier Wilson of London spoke on organic nervous disease in identical twins, reporting on four sets of such which have come under his observation. The name of only one continental European surgeon appears in the programme—namely, Dr. René Leriche of Strasbourg, who has reviewed the surgery of the sympathetic nervous system before the American Surgical Association. There are many subjects of interest mentioned in this programme, and as some of the entries are accompanied by brief abstracts an idea may in those cases be gleaned of the probable nature of the contributions. The remarkable case of Miss Helen Keller is the subject of papers in the otological and the neurological sections. It will be remembered that this patient, who had been blind, deaf, and dumb from infancy, was trained to a very high degree of knowledge and culture by the devoted efforts of Miss Sullivan of the Perkins Institution at Boston, on the lines followed by Dr. S. G. Howe in the teaching of Laura Bridgman, whose brain is to be the subject of discussion by the American Neurological Association. Before the same society a paper is to be read on Charles Darwin and Joseph Leidy of Philadelphia. The abstract postulates the equal importance of these two writers as "the two greatest biologists of the nineteenth century," showing how much a change of some seventy-five degrees of longitude may have on estimates of the relative importance of scientific achievements.

## CONFERENCE ON RHEUMATIC DISEASES.

ARRANGEMENTS have now been completed for the Conference on Rheumatic Diseases to be held at Bath on May 10th and 11th, of which we gave preliminary particulars on March 24th (p. 510). The programme has been drawn up with great thoroughness, and everything points to a very successful and profitable series of discussions. The three main sessions, devoted respectively to social aspects, causes, and treatment, will be presided over by Lord Dawson of Penn, Sir Humphry Rolleston, and Sir Farquhar Buzzard. The scope of these discussions will embrace rheumatic fever, both acute and subacute, chronic multiple arthritis, fibrositis, and degenerative arthritis. The proceedings will open on Thursday, May 10th, at 2.30 p.m., with a civic welcome by the Mayor of Bath, Alderman Cedric Chivers, and an inaugural address by Sir George Newman, president of the conference. The programme of social entertainments includes a dinner party given by the Mayor at the Guildhall on Thursday evening, followed by a *conversazione* at the Pump Room, when the guests will be received by the Mayor and the Mayoress (Madame Sarah Grand); and a luncheon on Friday, given by the chairman and members of the Bath Division, British Medical Association. On Saturday the Bacteriological Section of the Royal Society of Medicine will hold its annual meeting at Bath, when demonstrations will be given at the Hot Mineral Baths and Royal Mineral Water Hospital. These will be open to all those attending the Conference on Rheumatic Diseases.

## A CORONER'S JURY AND HOSPITAL ARRANGEMENTS.

No particular authority attaches to the rider of a coroner's jury. It is, in fact, as a rule a generalized expression of opinion based on the circumstances disclosed in the one incident with which they have been concerned. Like most generalizations from a single instance in any branch of investigation, the presumption is that it is wrong. When, however, such a rider is encouraged and endorsed by the coroner it becomes of somewhat more importance, for the coroner is a man with either a medical or a legal training, or both, who has probably had experience of many inquests. Nevertheless, even then the idiosyncrasies of the coroner have in some cases to be borne in mind. There is perhaps some justification for taking public note of the rider added by a jury to their verdict of "Death from natural causes" at a recent inquest upon the death of an elderly man who had been brought to Guy's Hospital and, after a careful examination, sent thence to St. Giles Hospital, Camberwell. After saying that the house-officer who saw the patient "showed all due care, and that no blame was attached to him," the jury added that "they considered that the system which allows patients to be transferred from one hospital to another on the opinion of one doctor only (and that a junior house-officer) is gravely unsatisfactory, and that no patient should be so transferred without being seen by two resident officers, both of whom should initial the removal papers." The coroner himself asks that the hospital authorities will inform him what steps they propose to take with the view of preventing such "regrettable occurrences." He will no doubt receive a courteous, and perhaps a reasoned, reply, but the medical committee of the hospital and the profession generally can scarcely be expected to do other than dissent from the implications of the rider and the request. These appear to be two: (1) That there is some legal right to question the propriety of a practitioner undertaking an ordinary medical service by reason of his age or experience; and (2) that the decision as to how a patient is to be dealt with must in no case be made on the authority of a single practitioner. With regard to the former it is sufficient to

say that it is registration by the General Medical Council which determines the legal status of a medical practitioner. All such practitioners are, in law, upon an equality, and any legal inquiry as to competence should be tested by that criterion. To adopt any other attitude would result in the subjection of every medical practitioner to a challenge as to competence, which is irregular in law and would be variable in practice. With regard to the second implication, it is enough to point out that decisions in every way comparable to those referred to have to be made, not merely at hospitals, but by every private practitioner in active practice every day; and that to accept a recommendation such as that of the coroner's jury would not only entail absurd administrative inconveniences, but would belittle the ordinary responsibility of registered medical practitioners in general, or would at least cast a grave reflection upon the competence of hospital medical officers in comparison with other members of their profession.

## A CAUSE OF NATURAL VARIATION.

THE occurrence of occasional variants and the perpetuation of them by natural selection is a fundamental conception of the Darwinian theory, and various causes have been suggested for this natural variation. There are probably a multiplicity of factors at work. In a short note in *Nature* A. R. Olson and G. N. Lewis<sup>1</sup> of the Chemistry Department of the University of California direct attention to an agency which they believe plays an important, if not a predominant, part in producing variations among plants and animals. It has been shown that the treatment of the fruit fly and the tobacco plant by  $x$  rays produces new and permanent varieties far in excess of those normally occurring, both as regards number and difference from the parent. When a bud of the tobacco plant was irradiated 80 per cent. of the resulting seeds which germinated were decided variants, the variation from one planting being greater than what had been noted in the normal plant for over a quarter of a century. Not all of the variants were fertile, but others seemed to be more fertile than the normal plant. The authors believe that such variations as actually occur in *Nature* are largely due to the reactivity of the environment. Their suggestion is an interesting one, but would be more captivating if it could be shown that there was an unusual variability of the fauna and flora in places where radio-active materials occurred in abundance.

THE Morison Lectures will be delivered before the Royal College of Physicians of Edinburgh by Dr. John Carswell on Monday, Wednesday, and Friday, May 7th, 9th, and 11th, at 5 o'clock. The subject this year is "Psychology and medicine."

THE second St. Cyres Lecture will be given by Professor K. F. Wenckebach in the Barnes Hall of the Royal Society of Medicine on Wednesday, May 16th, at 4.30 p.m. The subject will be "The heart and circulation in a tropical avitaminosis (beri-beri)." Tickets of admission may be obtained from the Secretary of the National Hospital for Diseases of the Heart, Westmoreland Street, W.1.

A Scientific Evening will be held at the Royal Free Hospital on May 9th, at 8.30 p.m., when various demonstrations will be given and cinematograph films shown. Further information may be obtained from the secretary at the hospital, Gray's Inn Road, W.C.1.

<sup>1</sup> *Nature*, April 29th, 1928, p. 673

## ANAESTHESIA BY THE RECTAL INJECTION OF OIL AND ETHER AND OTHER DRUGS.

A REVIEW of the present position as regards the rectal administration of ether and oil as an anaesthetic in surgical practice, and of morphine, magnesium sulphate, and ether analgesin in surgical and obstetric practice, by Dr. Robert A. Hatcher, professor of pharmacology in the Cornell University Medical College, has been published as a series of special articles, which opened in the *Journal of the American Medical Association* for December 17th, 1927.

### I.—RECTAL OIL-ETHER ANAESTHESIA.

Professor Hatcher deplures the fact that Gwathmey, its originator, should have attempted to develop the method without adequate animal experimentation, with the result that theories have been based on erroneous views, and accepted and repeated by later writers; he proceeds to quote numerous extracts from the literature of the subject, and, after discussion, to summarize his conclusions. These are as follows.

1. That oil-ether mixture is an advance over other methods of rectal or colonic administration.
2. That anaesthesia is readily induced with mixtures of varying proportions, but in practice a mixture containing equal volumes of oil and ether is probably the most suitable, since resultant bowel irritation is less than when higher percentages of ether are used.
3. That the bowel must be washed out immediately after the operation is over, and all residual mixture removed. Prior to introduction of the mixture the neighbouring skin must be adequately protected from possible leakage of oil and ether by smearing the parts with vaseline.
4. That ether is absorbed from the colon and not from the rectum; consequently the warmed mixture must be introduced slowly for a period of some ten minutes high up into the colon proper.
5. That the advantages of the method are: (a) It spares to some extent the respiratory passages. (b) There is less salivary and bronchial secretion. (c) It lacks certain disagreeable features of ordinary inhalation methods. (d) The excitement stage is often lacking, and when present is usually of short duration. (e) There is less nausea and vomiting during anaesthesia and after operation. (f) There is a clear field left for the operator in head and neck cases.
6. That the disadvantages of the method are: (a) The depth of anaesthesia is not under perfect control, as is the case with inhalation anaesthesia, and in certain cases this fact may outweigh all advantages. (b) There is always some intestinal irritation after administration, and in a small number of cases this may be severe and accompanied by haemorrhage, and may even end fatally. (c) There is greater injury to the liver with this method than with inhalation anaesthesia when similar quantities of ether are administered.
7. That it shares with inhalation anaesthesia the following drawbacks: (a) It has the same pharmacological contraindications. (b) It cannot be used in a room with an open flame. (c) The patient has to be kept under observation until consciousness returns, and in the case of oil-ether anaesthesia this period may be prolonged. (d) It often needs preliminary medication such as morphine injections, or subsequent inhalation anaesthesia where deep narcosis is required.
8. That detailed statistical studies of accidents due to anaesthesia conducted in various ways are urgently required. These must contain suitable classifications to permit of the correct evaluation of varying factors. Until forthcoming, no comparisons as to the relative safety of any method as compared with any other can be made. The dose of ether should be regulated according to the weight of the patient, and it seems probable that 2 grams of ether per kilogram of body weight is the maximum dose that can be given with safety, following a hypodermic injection of from one-sixth to one-fourth of a grain of morphine, the latter dose depending also on body weight.
9. That the choice of an anaesthetic and its mode of administration need the same careful consideration whatever be the method of anaesthesia employed. Routine methods are dangerous and irrational.
10. That lack of adequate statistical studies of the occurrence of post-operative pneumonia and its causes makes it impossible to state whether this follows oil-ether anaesthesia with greater or less frequency than other forms of anaesthesia.

### II.—SYNERGISTIC ANALGESIA.

The author next proceeds to discuss so-called synergistic analgesia. This was introduced by Gwathmey in 1921 and consists, in the addition to the usual hypodermic injection of morphine, of a small amount of magnesium sulphate. He claims that this addition increases the value of the injection from 50 to 100 per cent., and so allows much smaller quantities of ether to be used. Gwathmey divides the stages of anaesthesia into four—the first being that of excitement, the second that of analgesia, the third that of surgical anaesthesia, and the fourth that of overdosage. He proposes to make use of the first and second stages only, in which excitement is abolished, so as to make expert supervision unnecessary, and it is with synergistic analgesia that he proposes to effect this result. Hatcher discusses the literature of the subject which followed Gwathmey's original paper, and comes to the conclusion that the evidence is not convincing that the use of from 2 to 6 c.cm. of a 50 per cent. solution of magnesium sulphate materially lessens the amount of ether required by rectal administration to induce anaesthesia. *Per contra* there is no doubt that the amount of morphine used has a decided influence on the total quantity of ether required; but there is ample evidence that the action of morphine on the respiratory centre is synergistic with that of ether and magnesium sulphate, and that numerous deaths have resulted from their combined use. What has been said concerning the advantages and disadvantages of rectal anaesthesia applies equally to the so-called synergistic analgesia, and the evidence brought forward by Gwathmey in support of his claims with regard to the latter form of analgesia is not convincing. Moreover, expert supervision is still as necessary as ever with regard to the welfare of the patient submitting to the induction and maintenance of anaesthesia.

### III.—ANALGESIA IN CHILDBIRTH.

Hatcher next discusses analgesia in childbirth, with particular reference to the claims of synergistic analgesia, and after citing numerous papers on the subject comes to the conclusion that synergistic analgesia is by no means safe in the hands of the unskilled, and that the commercial exploitation of proprietary products based on the Gwathmey formulae is potent for much harm, since it will inevitably tend to promote the thoughtless and ill-advised use of the method. No method of inducing analgesia is suitable for universal use. So-called painless childbirth is frequently a most difficult problem. The general practitioner is often misled into believing that he can secure better results by the method that he reads about than by the methods with which he is familiar, when in truth it presents no essential advantage, and may prove inferior in his hands to that in which he has acquired a degree of skill.

The Gwathmey method skilfully used will undoubtedly mitigate the pains of labour, but no woman should be promised a painless labour, since even Gwathmey admits that only a small proportion of patients have relatively painless labour.

Obviously the dosage of morphine and ether should be calculated on the weight of the patient. After an average dose of morphine the maximum dose of ether for a woman of average size amounts to about 2½ ounces. The quinine used in the Gwathmey method frequently overcomes the retarding effect of morphine, but labour is sometimes prolonged even with large doses of quinine. A great difficulty lies in the estimation of the time that will elapse before labour is completed, with consequent uncertainty as to the time when the enema should be administered. Talkativeness and motor unrest are difficulties which, in the absence of suitable attendants, may prove troublesome to deal with. Rectal irritation may be important.

The question of the value of magnesium sulphate with morphine and ether cannot be answered at present. Many state that it has a clinical value, but there is no evidence that it potentiates the action of morphine, and animal experiments show that there is a summation of toxic effects. There is probably also a summation of therapeutic effects.

On the whole, then, the opinion of the author would

seem to be that rectal oil-ether anaesthesia and analgesia, whether used with or without other drugs such as magnesium sulphate or quinine, should be induced only in selected cases and at the hands of the skilled anaesthetist. The methods, even in the hands of the skilled, so far from being harmless, show, or appear to show, unfavourable results with greater frequency than is met with usually in the case of the various inhalation methods. The further inference is obvious and needs no elaboration. The enthusiastic claims of the pioneers, as so often happens, have not been borne out by the experience of subsequent workers, and accidents have happened which cannot be explained away on the assumption that a faulty technique was entirely to blame. Undoubtedly rectal anaesthesia and analgesia have a place in the anaesthetic arm, but it has by no means as yet been proved that this place should be granted them at the expense of the older methods. An examination of the author's papers in the original will convince most British anaesthetists that his conclusions are sound and that the anaesthetic millennium has not yet been reached.

### TETRA-ETHYL LEAD IN MOTOR SPIRIT.

*Committee of Inquiry: Evidence from America.*

The first ordinary session of the committee appointed by the Minister of Health, Mr. Neville Chamberlain, to inquire into the possible danger to health resulting from the use of motor spirit containing lead tetra-ethyl, or similar lead-containing compounds, was held at the Office of Works on April 30th. The names of the committee are as follows:

*Chairman:* Sir Frederick Willis, K.B.E., C.B., who was until recently Chairman of the Board of Control.

*Departmental Representatives:* Ministry of Health: Sir George Buchanan, C.B., M.D. Home Office: Dr. J. C. Bridge, F.R.C.S. (Senior Medical Inspector of Factories). Air Ministry: Mr. D. R. Pye, M.A. (Deputy Director of Scientific Research). Medical Research Council: Sir Charles J. Martin, C.M.G., D.Sc., F.R.S., F.R.C.P. (Director of the Lister Institute). Sir Robert Robertson, K.B.E., D.Sc., F.R.S. (Director of Scientific and Industrial Research). Dr. C. H. Lander, F.R.S. (Director of Fuel Research).

*Non-official Members:* Mr. A. Chaston Chapman, F.R.S., F.I.C., Sir William Wilcock, K.C.I.E., C.B., M.D., F.R.C.P., Professor W. E. Dixon, M.D., F.R.S.

*Secretary:* Mr. S. F. S. Hearder, Ministry of Health, Whitehall, S.W.1.

Evidence was taken from representatives of the American producers and the British distributors of ethyl petrol, and from an official of the Air Ministry regarding experience in its use.

Dr. GRAHAM EDGAR, director of research to the Ethyl Gasoline Corporation, New York, stated that his company had placed the full results of its investigations at the disposal of the committee. There had been, in 1924, five fatalities and a number of cases of poisoning at Bayway, New Jersey, among men developing a new process for the manufacture of lead tetra-ethyl, but this had nothing to do with ethyl gasoline. Several American cities banned the sale of this spirit, and eventually the matter was taken up by the United States Public Health Service. Officially, it was found that there was no hazard to public health from the use of ethyl gasoline, and no grounds for prohibiting it, provided its distribution and use were controlled by proper regulations. Following these investigations the cities which banned the spirit withdrew their objection. The United States Bureau of Mines had exposed animals from three to six hours per day to exhaust gases from an engine burning this spirit; after a period of eight months there was no storage of lead and no symptom of poisoning. Tests on human beings were made by exposing groups of men as severely as possible to ethyl gasoline in various ways, with groups not so exposed as controls. Searching medical examination established that no individual in any of the groups gave evidence of lead poisoning or any other injury to health resulting in any way from ethyl gasoline. The experience of the corporation had been that when their product was introduced into new territory reports of alleged injury were numerous, while from territory in which its use had been extensive such reports were negligible. Reports were investigated wherever possible; in no case had there been any substantiation of the rumour that any injury could be traced to the use of ethyl gasoline. Referring to the result of an investigation recently published in an English newspaper, Dr. Edgar said no conclusions whatever could be reached from consideration of data so fragmentary. Replying to questions, he stated that theirs was a new industry, and that any material or fluid having lead in it had to be closely observed. Some of the men regularly handling ethyl had been rigorously examined during the past ten years, and would continue to be watched for the next ten years, in view of

possible cumulative effects. As yet there had been no deterioration in the health of the staff.

The rapid extension in the use of ethyl gasoline in Canada and the United States was described by Mr. A. M. MAXWELL, vice-president and sales manager of the Ethyl Gasoline Corporation, who added that last year the corporation, which supplied thirty-six of the major oil companies, did not receive a single complaint of damage to health from users. Mr. H. S. TEGNER of the Anglo-American Oil Company said his company was thoroughly convinced of the safety of the tetra-ethyl mixture before marketing it in England. Although its representatives had studied every available source of evidence, and had been intimately concerned in handling the product in their blending plants, where the staffs were regularly inspected by competent medical practitioners, they had not encountered the least indication that the handling of the spirit did or could produce the slightest deleterious effects to the worker, the motor car user, or the public generally.

Mr. PYE, representing the Air Ministry, stated that exhaustive experiments had been carried out in the laboratory and during long evolutions of two squadrons. At no time had there been any report of illness among the personnel handling ethyl spirit. In high-speed aero engines the proportion of tetra-ethyl lead used in the petrol was often considerably higher than in the mixtures sold commercially. Dr. BRIDGE of the Home Office said the Anglo-American Oil Company fully consulted that department before they put ethyl spirit on the market. The inquiry was adjourned.

### Ireland.

*Farewell Dinner to Professor J. A. Lindsay, Belfast.*

On the occasion of his leaving Belfast to take up residence in London, Dr. James A. Lindsay, Emeritus Professor of Medicine in the Queen's University, Belfast, and senior consulting physician to the Royal Victoria Hospital, was, on April 24th, entertained at a complimentary dinner. Professor Lindsay's hosts were his colleagues of the visiting staffs of the Royal Victoria Hospital and the Belfast Maternity Hospital. He has for some years past been chairman of the boards of both these institutions, and in that capacity has exercised an important and beneficial influence on their development. In the after-dinner speeches his colleagues found much to recall in connexion with his valuable services in raising the standard of the local hospitals and in the advancement of medical education in Belfast. Professor R. J. Johnstone, M.P., a former pupil of the guest of the evening, paid his tribute in some amusing verses composed for the occasion. Professor Lindsay is a past-president of the Ulster Branch of the British Medical Association, and was president of the Section of Medicine when the Association held its Annual Meeting at Belfast in 1909. He will be greatly missed by members of the medical profession throughout Northern Ireland, who unite in wishing him health and happiness in his retirement.

*The Coming Public Health Conference in Dublin.*

The aims and objects of the public health conference which is to be held in Dublin from August 15th to 20th were the subject of an address by Sir William Thompson, M.D., at a recent meeting of the Dublin Rotary Club. It was, he said, well known to everyone that medicine and surgery had made great progress during the latter part of the nineteenth century and up to the present time, but it was recognized that in future it would be maintained more in the direction of prevention of disease than otherwise. For some years past special attention had been devoted to prevention, not only by the medical profession, but by big business firms and public bodies having the health and welfare of their employees and of the community at heart. It was to forward this object that over forty years ago the Royal Institute of Public Health was established. The Dublin Medical School, which deservedly held a world-wide reputation, was, said Sir William Thompson, one of the first to institute a diploma or degree in public health—as far back as the sixties in the last century—and, happily, they had still with them Sir John Moore, who was one of the earlier graduates. Dublin business houses had not been behindhand in looking after the health of their employees, notably the firms of Guinness and Jacob. The holding of the yearly congress in large centres throughout

Great Britain, Ireland, and on the Continent, as the Instituto diil, was a means of bringing together those interested in public health and allied work to discuss the problems which arose from year to year. In addition, this served, through the press, to educate the public and keep it informed of the progress made in the prevention of disease, which would add to the health and happiness of the community. Last year the congress was held in Belgium, in 1926 in Bristol, and seventeen years ago it was held in Dublin. The congress was made up of delegates appointed by universities, medical colleges, boards of health, and other institutions interested in public work, through invitations sent by the Institute in London to such bodies in Great Britain, Northern Ireland, the Continent, United States, and Canada. In Saorstát Éireann the invitation was sent by the executive committee of the congress. The Mansion House had been placed at the disposal of the congress for offices, by kind permission of the city commissioners. The matters to be discussed were of practical importance from every point of view, and should be interesting and instructive to the citizens of Dublin and the people throughout the Free State. They had some of the most important public health workers in Great Britain and the Continent coming across. Sir William Milligan of Manchester; Dr. Varrier-Jones, superintendent of Papworth Tuberculosis Settlement; Sir Henry Gauvain; Dr. Stevenson of the British Ministry of Health; Dr. Leighton of the Scottish Board of Health; Dr. Trimble, tuberculosis officer, and Dr. Fulton, Children's Hospital, Belfast; Dr. Wurtzen of Denmark; and Professors Abercrombie and Beattie of Liverpool. From an expert and scientific point of view the success of the congress was ensured. Dublin, he continued, had always been noted for its hospitality, and the executive committee was doing its utmost to live up to past traditions. It might be asked if any good results followed the 1911 congress, and what benefit was expected to accrue from the coming congress. One had no hesitation in saying that those who took part in the 1911 congress were unanimously of the opinion that much benefit resulted therefrom. Public health conditions had advanced considerably during the seventeen years, although the great war and their own unsettled conditions intervened. He wished publicly to pay a tribute to the Ministry of Local Government and Public Health since 1922. There was now in Saorstát Éireann one of the best means for the appointment of medical officers of health, medical officers, and all appointments on health—through the selection board. The adoption of this system was a bold and courageous step for the Executive Council to take; from a political point of view it alienated some support, but, when carried on for years, it ensured a body of public health enthusiasts second to none in any other country. Thus the health of their people would be improved and prosperity and happiness ensue.

#### The Rotunda Hospital, Dublin.

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland on April 20th Dr. Bethel Solomons read the clinical report of the Rotunda Hospital for the year 1926-27, and films were shown to illustrate the appearance of the Fallopian tubes after the injection of lipiodol and the method of performing x-ray pelvimetry. Dr. Solomons announced that the x-ray plant installed during the year had proved useful in obstetrical and gynaecological diagnosis and treatment. The pathological laboratory had been reopened. The scope of the ante-natal department had greatly increased, and it was suggested that ante-natal study should be made compulsory in universities. A small ward had been opened for the treatment of infants. The British Medical Association standard of morbidity had been used and the "Rotunda" method also was followed; the results proved to be identical at the end of the year. The number of Caesarean sections had been large in spite of attempts to avoid this operation. The treatment of eclampsia had scarcely altered. The number of admissions (673) to the gynaecological wing was a record for the hospital. The gynaecological mortality was 0.95 per cent. The master of the hospital thanked his assistants, Drs. Taylor and O'Donel Browne, for their share in the preparation of the report, and he

referred to the excellent work of the matron and nursing staff during the year. Dr. Gibbon FitzGibbon, president of the Section, said that the treatment of septic cases at the Rotunda Hospital was apparently much the same as it had been at the end of his term as master. He did not put much faith in colossal iodine, but thought that it was beneficial in some cases. In the last few years treatment by vaccines and antitoxins had decreased considerably. When performing Caesarean section the lower segment operation was more difficult than the classical form, but it was the better procedure; he did not think that it would have much more influence on the recovery of an actually infected case, and believed that such cases should always be drained at the time of operation. In no case of accidental haemorrhage was plugging of the cervix indicated. He had had most disastrous results in cases of placenta praevia which had been sent into the Rotunda Hospital plugged. Sir William Smyly emphasized the importance of educating medical students in midwifery, and commented on the recent improvements at the Rotunda Hospital. Dr. Louis Cassidy said that at the Coombe Hospital it had been found that at least 50 per cent. of the women who developed sepsis had not been interfered with. He believed that there were three causes for sepsis: the possibility of toxins, a septic focus in the teeth, and residual urine in the bladder. Foetal mortality seemed to be the main difficulty in midwifery at present; this was largely due to lack of ante-natal treatment, and the new ante-natal clinic at the Rotunda Hospital should be of great value. Dr. J. S. Quin said that of all the improvements in the Rotunda Hospital none was of more value to students than the clinic for infants. Dr. R. J. Rowlette remarked that a great forward step had been taken in restoring the pathological laboratory at this institution. Dr. N. McI. Falkiner suggested that a detailed register of the patients who came to the ante-natal department and were delivered in the Rotunda Hospital should be kept and compared with the records of those patients who did not attend; only in this way could the value of the department be estimated.

## England and Wales.

### A Private Patients' Home Insurance Scheme at Norwich.

THE opening of a new private patients' home at the Norfolk and Norwich Hospital marks the beginning of an interesting effort to meet the needs of the middle classes in respect of hospital facilities. In the scheme now in force there the provision of pay beds is associated with an insurance scheme, the membership of which is limited to persons whose incomes fall within certain defined limits. Admission will be restricted to persons whose incomes do not exceed (a) for single persons, £350 per annum; (b) for married couples without children under 16, and widows and widowers with children under 16, £450 per annum; and (c) for married couples with children under 16, £550 per annum. A yearly premium of £1 10s. will entitle a member to free in-patient and certain special out-patient treatment for himself, his wife, and any children under the age of 16. The scheme embraces "hospital" treatment only, and before a patient may be admitted he must be seen by a member of the hospital staff in consultation with his own doctor; the fee for such consultations is not provided for by the premium. Only members of the hospital staff can treat patients under the scheme. Maternity, mental, and infectious cases cannot be admitted. The premium covers all surgical, medical, and maintenance costs, including those of special departments, while in hospital, but not the cost of any special appliances, drugs, or instruments which may be ordered for treatment after discharge. Power is taken by the management committee to control the extent to which members may remain in hospital as in-patients or attend as out-patients; no one may remain as an in-patient for more than four consecutive weeks, or attend as an out-patient for more than eight weeks in any six months, except by special arrangement. The department is managed on behalf of the hospital board by a committee, on which subscribers to the

insurance scheme are represented. Persons who are not members of the scheme, so far as accommodation permits, may be received as private ward patients at a charge of £4 a week; this does not include medical attendance, which will be arranged by the patients themselves, but its cost must not exceed fifteen guineas. The admission of non-members is subject to the conditions regarding income limits and preliminary consultation which apply to members. Simultaneously with the inauguration of the private patients' department, the hospital authorities have determined to reserve the right to refuse admission as ordinary patients to anyone whose income, or in the case of dependents whose parents' income, exceeds £300 per annum. The only exceptions are members of the Sunday and Saturday Fund Contributory Scheme who are entitled to medical benefit under the National Health Insurance Act. Considerable interest attaches to the financial basis of the private patients' insurance scheme and to the arrangements for the remuneration of the honorary medical staff. The first charge on the year's contributions will be a payment to the hospital of an amount for each private patient admitted, based on the average cost per patient in the general wards, plus 25 per cent; the second charge will be an equal amount to be paid to the honorary medical staff. A proportion will then be set aside for capital charges and fresh expenditure, and any balance remaining will be divided equally between the hospital and the medical staff. The distribution of the amount available for these practitioners will be in proportion to the work done by each. It has been estimated that with the premium stated and a 4 per cent. sickness rate the scheme should be financially successful; that with a 5 per cent. rate there would be a profit; but that with a 6 per cent. rate the amount for distribution to the honorary medical staff would have to be reduced. It will be noted that the hospital stands in relation to the medical staff as preference shareholders in a trading concern to ordinary shareholders; its fixed share of the available funds must be met before other payments can be considered. The new building, which stands in its own grounds near the parent institution, was formally opened on April 20th by the Hon. Sir Arthur Stanley, who remarked that it was the first time he had heard of a combination of a private patients' home with a contributory insurance scheme, and expressed his special interest in seeing how their scale of payment would work out.

#### Durham University Medical Society: Visit to Denmark.

The summer meeting of the University of Durham Medical Society took the form of a visit to the University and hospitals at Copenhagen from March 31st to April 6th, the party consisting of forty-five students and members of the staff of the Newcastle Medical School. The visit was arranged at the invitation of the Danish Students' National Union and the medical faculty of the University, with whom the British Chargé d'Affaires, Mr. Millington Drake, and Dr. Vincent Naeser had co-operated with such enthusiasm that a very warm welcome was given to the party. Meetings were held at the Rigshospital on March 31st and April 2nd. A lecture was given by Professor Faber on the medical curriculum in Denmark. The course of study occupies seven years, and is invariably followed by two years' residence in hospital after the final examination. One of the chief features is the "weeding-out" process in the third year at the end of the courses in anatomy and physiology, and after some preliminary hospital work. More than a third of the students are rejected at this stage. The English students felt that this obstacle, savouring of the "survival of the fittest," probably accounted for the very high standard of work in the remaining years of the medical curriculum. Professor Faber continued with a clinical lecture on undulant fever due to *B. abortus* infection, a disease which has been recently recognized to be very prevalent in Denmark, and Professor Lundsgaard gave a very practical clinical lecture on arterio-sclerosis, with an account of his own researches on the subject. Other items included a demonstration by Professor Schaldemose, who operated in the big surgical amphitheatre of the hospital; a lecture on vitamins by Professor Bloch, who showed cases of xerophthalmia, and gave an account of this deficiency

disease and the epidemic of it which appeared in Denmark in 1918; and a lecture by Professor Krøgh on capillary physiology, illustrated by a cinematograph demonstration of the blood cells in the capillaries, which aroused great interest. The remaining days were devoted to Professor Monrad's hospital, to the Bispebjerg Hospital, to the Finsen Institute, and the Serum Institute, where Dr. Thorvald Madsen received the party and lectured. One of the most interesting meetings was held on the outward journey in the s.s. *Arcturus*, with Dr. J. C. Spence, the president, in the chair, when Mr. Rutherford introduced a discussion on sea-sickness. The subject was considered from the stand-points of physiology and therapeutics, and current theories were fully discussed in the light of personal clinical knowledge. Captain Hjelt took part in the discussion, and gave a vivid account of his own experiences of cases and their treatment.

## Correspondence.

### TROPICAL AUSTRALIA.

Sir,—I am glad to reply to the letter of Dr. Andrew Balfour, published in the *British Medical Journal* of January 7th (p. 30). The Commonwealth statistician and actuary, Mr. C. Wickens, furnishes me with the following statement of fact.

"With reference to the letter relative to tropical Australia written by Dr. Andrew Balfour, a copy of which was received under cover of yours of March 5th, I am appending particulars taken from census reports for Queensland, which will serve to refute the statement that Australians employed in the cane-fields are very largely of Italian origin.

#### "Census Reports 1861-1921.

"The reports up to 1868 indicate that the number of Southern Europeans in Queensland was negligible. In 1871 and following census years the number of Italian-born persons in Queensland per thousand of the population was as follows:

1871	...	0.72	1901	...	1.70
1881	...	1.17	1911	...	1.54
1891	...	1.11	1921	...	2.44

"In 1921 separate figures were obtained for tropical and non-tropical divisions of Queensland. The Italian-born population resident at that date within the tropics represented 8.37 per thousand of the tropical population, and the Italian-born population south of the tropics 0.56 of the non-tropical population. The percentage of the population in respect to birthplace was also tabulated for the States of Australia in 1921. The results obtained showed that the number of persons enumerated in Queensland who stated that one or both parents were born in Italy was 3,458, representing about 4.5 per 1,000 of the total population."

It should be remembered that the State is divided into tropical and non-tropical Queensland. The distinction is arbitrary in one sense as it is based on the Tropic of Capricorn, whereas the whole of Queensland is north of the 29th parallel. From Mr. Wickens's statement it will be seen that the answer to Dr. Balfour's suggestion that the white race in tropical Queensland is of Italian origin is that it is not correct. A healthy white race which is not Italian has been reared in tropical Queensland for several generations. The infantile and the adult death rates are lower than in almost any other place in the world, and the most thorough physiological investigations have shown no deterioration which can be measured by the means at our disposal. Towards the end of his letter Dr. Balfour refers to the low-lying lateral of tropical Queensland. Might I suggest that whether a country is low-lying or hilly tells us very little? It is the accurate record of the wet-bulb temperature that indicates the stress to which human beings are subjected. What may lie in the future I do not know, but I can definitely state that in tropical Queensland a vigorous white race, which contains only a small percentage of Italians, is being reared and shows no signs of deterioration. In fact, the suggestion that there is deterioration, when made to some of the residents in tropical Queensland, is received with ridicule. Those who saw the soldiers Queensland sent to the front during the great war will understand the incredulity.—I am, etc.,

Melbourne, March 12th.

JAMES W. BARRETT.

# CARDIOSPASM (SO-CALLED ACHALASIA OF THE CARDIA).

SIR,—In a previous letter (April 7th, p. 610) I furnished evidence combating the theory of achalasia of the cardia and further confirming that of cardiospasm. Dr. Hurst maintains, however, in your issue of April 21st (p. 690) that my letter so seriously misstates the evidence in favour of achalasia and against cardiospasm as to call for a reply.

Dr. Hurst writes: "It is not clear what he can mean by cardiospasm, as he denies the existence of a cardiac sphincter." I certainly deny the presence of an anatomical sphincter, but recognize the presence of a physiological one at the lower end of the gullet. At the British Medical Association meeting in Liverpool (*British Medical Journal*, October 19th, 1912, p. 1047) I showed two dissections, each including the lower part of the oesophagus and upper part of the stomach, in which the muscular layers had been separated. These demonstrated both muscular coats to be of uniform thickness and without any special aggregation of fibres at or near the cardia. The textbooks are in agreement as to the non-existence of an anatomical sphincter in this situation. It is even stated on good authority that a cardiac sphincter is found in no animal (D. M. Greig, *Edinburgh Medical Journal*, August, 1921). In view of the consensus of opinion on this question it is interesting to learn from Dr. Hurst's letter that he and others have demonstrated an anatomical cardiac sphincter. The exhibition of specimens of so rare a nature would be welcomed at a meeting of laryngologists or anatomists. I might mention that my preparations are still available for comparison.

Dr. Hurst states that degeneration of Auerbach's plexus "must result in failure of the sphincter to react to stimuli. The sphincter cannot, therefore, perform its normal function of relaxation nor its rarely exercised power of contraction; it consequently remains closed—that is, in its normal position of rest." It seems to me futile in our present state of knowledge to theorize as to the effect of the degenerated plexus on the cardia. I must, however, take exception to Dr. Hurst's statement that the "sphincter," or, as I prefer to term it, the cardiac canal, is closed during rest. On the contrary, it is rhythmically widening and narrowing with inspiration and expiration respectively, both in the normal subject and in the patient with cardiospasm. In the latter, however, when the oesophagoscope comes into contact with the upper end of the cardiac canal this is seen to contract vigorously, and resistance, sometimes strong, but at least greater than normal, is encountered. These findings seem to me to admit of only one interpretation—namely, spasmodic contraction.

Obviously Dr. Hurst's acquaintance with the endoscopic examination of the oesophagus is limited, or he would not have stated that "it is difficult to pass a rigid instrument past the angle formed by the sphincter with the rest of the oesophagus, particularly when the latter is so dilated that its lower extremity is actually below the entrance to the sphincter," for there is no special difficulty unless in overcoming firm spasm, and under such conditions the oesophagoscope guided by the eye is safer than a mercury tube passed blindly; nor would he have made the amusing suggestion that I have mistaken the spasm of the diaphragm caused by pressure of my instrument for spasm of the cardiac sphincter.—I am, etc.,

Glasgow, April 24th.

A. BROWN KELLY.

\* \* This correspondence seems to have come full circle, and may now, we think, be regarded as closed, except for corrections of fact.

## DELAYED NOTIFICATION OF TUBERCULOSIS.

SIR,—Dr. Rose Jordan's letter under the above title published in the *British Medical Journal* of April 21st (p. 692) raises some interesting and important points in regard to the notification of tuberculosis. It is, I think, unfortunate that, in giving the percentage, she does not divide the non-notified cases from those dying within three months of notification.

In the administrative county of Lancaster we have for many years made special investigations into the reasons for non-notification and delayed notification. Dealing,

then, first with the non-notified fatal cases, we have the following results: In 1927 there were altogether 54 pulmonary (representing 4.8 per cent. of the total pulmonary deaths) and 42 non-pulmonary cases (representing 14.1 per cent. of the total non-pulmonary deaths) reported for the first time at death. The circumstances of non-notification were investigated in each instance, and are as follows: (a) that in 8 of the 96 deaths the doctor was only called in attendance a few days prior to death; (b) that in 28 cases notification was not made owing to the misinterpretation of the regulations—for example, previously notified in another sanitary district, disease commenced prior to 1912, temporary resident, attended by more than one doctor and notification believed to have been made by first practitioner; (c) that 38 cases presented considerable difficulty in diagnosis; (d) that in 5 cases the doctor accidentally omitted to notify; (e) that in 7 cases no doctor was in attendance; (f) that in 6 cases no information was ascertainable; and (g) that in 4 cases there was no apparent reason for non-notification.

With regard to delayed notification, we had altogether in the county 344 cases of pulmonary tuberculosis where the death occurred within three months of notification (the non-pulmonary cases were not specially investigated). Before the inquiry into these 344 pulmonary cases, 146 were deducted for such reasons as deaths outside county area, complicated cases presenting difficulty in diagnosis, deaths in public institutions, fulminating cases, and no doctor in attendance.

Inquiries were made in regard to the balance—namely 198—and it was ascertained that the period under the doctor at the date of notification was as follows:

Under 1 month	...	...	...	...	...	96
1 to 2 months	...	...	...	...	...	52
2 to 3 "	...	...	...	...	...	15
3 to 6 "	...	...	...	...	...	19
6 months and over.	...	...	...	...	...	16

198

Thus, 35 patients had been under their doctor three months or more prior to the date of notification, a percentage of 3.1 on the total pulmonary deaths (1,105) for the county for 1927.

This period of three months or more was taken by Dr. Jordan for her seven cases (if I have read her letter aright). While this is much too long a period to allow before the family doctor consults the tuberculosis officer, it must always be remembered that there are patients who will not easily agree to see the tuberculosis officer, and others do not disclose their symptoms to the doctors for some weeks.—I am, etc.,

G. LISSANT COX,  
Central Tuberculosis Officer, Lancashire  
County Council.

Preston, April 23rd.

## THE "CURE" OF PULMONARY TUBERCULOSIS.

SIR,—Dr. Carswell asks me a very proper question (April 21st, p. 692), but he is under a misapprehension as to my views on therapeutic immunization. I consider it essential for success against any infection that: (1) The antigen must be complete—it must contain all the microbes attacking the patient's tissues, hence the use of mixed infection antigens in the treatment of tuberculosis. (2) The antigen must be potent—that is, contain as great a toxin content as possible, so that antitoxin as well as antibacterial immunity can be achieved. (3) Such a dose must be attained as will produce sufficient antibodies to enable the patient's phagocytic cells to ingest and digest the infecting microbes and survive the process. (4) The doses must not be given at fixed intervals, but the interval must vary with the reaction of the patient.

In order to achieve potency the microbes for ordinary antigens are grown on agar containing 10 per cent. unheated human blood—a medium as close to a human tissue as it is possible to achieve. It might not be thought that microbes would lose much toxicity in twenty-four hours, but that period in the life of a microbe corresponds to something like two thousand years of human existence. The tubercle bacillus, owing to its lipid saturation in its

acid-fast form and its slow growth, has made the manufacture of a potent antigen difficult, and, except in the case of old tuberculin A T, special grinding apparatus has had to be devised. In A T Koch hoped for the presence of toxin freed from the bacillary body by autolysis. I think he achieved it to a certain extent, for I have always thought A T the best of all the ordinary tuberculins. In the manufacture of H.T.S. (human type tubercle bacillus solution) no special apparatus is required.

Dr. Carswell is exercised by the smallness of the dose, but 0.000000001 mg. actual weight of the original live tubercle bacillus, obtained by dilution, is a potent therapeutic dose of H.T.S., and must not be exceeded as a primary dose in the immunization of established pulmonary tuberculosis. He will realize, then, that 0.01 mg. is ten million times the primary dose. I feel that the patient is safe if I attain to a dose of 0.001 mg., but it is not always possible to do so, as the maximum dose varies with the individual.

H.T.S. is, therefore, a very potent antigen. I believe it to contain free toxin. I have made a solution of the bovine type (B.T.S.), but have found in practice that H.T.S. gives just as good results in "surgical" cases. Apparently the toxin of the tubercle bacillus is, like that of the diphtheria bacillus, fairly uniform in quality—of course, the ideal would be an autogenous tubercle bacillus antigen for each case. This answers the first part of Dr. Crawshaw Holt's letter (p. 692). I most thoroughly agree with the second part, for tuberculosis will not be controlled until contacts, infants, and calves are rendered relatively immune by preventive inoculation with tuberculosis.—I am, etc.,

Dublin, April 23rd.

W. M. CROFTON.

#### THE CAUSES OF ALCOHOLIC INEBRIETY.

SIR,—In your issue of April 21st (p. 691) Drs. George and Vincent lay greatest stress upon heredity as "a decided cause" of alcoholism. This is not borne out by the experience gained in the institution of which I am medical superintendent. It is true that not only patients, but their relatives also, are generally anxious to shift what they consider the opprobrium of inebriety from themselves to their defenceless forebears. In spite of this perhaps natural desire, only a small proportion can adduce any reliable evidence in support of such a scapegoat type of excuse; against which most of us know that where there has been marked parental excess the children tend to become rabid teetotalers. Drs. George and Vincent do admit that there are "quite an appreciable number in whom heredity and habit seemed to be absent as causal factors." In my experience their "appreciable number" is the vast majority, and the heredity factor when present is so accidentally, not causally. It would appear with at least equal frequency in a sample of the population taken in respect of any other affliction. The bugbear of heredity, which we all trail with us in some sort, stultifies therapeutic endeavour, though it serves as an ever-present help in time of trouble.

Careful psychological investigation in every case reveals the presence of those other factors which Drs. George and Vincent touch upon so lightly and dismiss so easily. My experience has convinced me that the essential underlying factor in alcoholism is the desire for the mental effect of alcohol, and not easy access to the drug, nor habit, nor heredity, which latter serve at most as auxiliary determinants. Of course, alcohol is an addiction drug, and the "alcoholist" is not able so to control himself and his dosage as to maintain the, to him, exactly desired effect. In aiming at what is to him "euphoria," he oversteps the mark and, like all neurotics, finds that his last state is worse than his first. Not infrequently addicts hate the taste of alcohol and refer to it as "the beastly stuff," but this does not prevent them from again having recourse to it when the adequate stimulus recurs.

Unless the prime importance of the individual psychological factor be appreciated a rational therapy and reorientation can hardly be expected. Concurrent and incidental determinants must, of course, be attended to, and so far as possible be removed, but the essential is to discover in each individual "alcoholist" the psychological

factors which motivate his flight to "alcoholic euphoria" at all costs, and in spite of the fact that he is aware that a price must be paid for this flight.—I am, etc.,

Caldecote, April 27th.

ALFRED E. CARVER.

#### "DRUNK IN CHARGE."

SIR,—This subject has again been brought forward in your issue of April 21st (p. 693). As the condition is so easily recognized by an onlooker, it is unfortunate that the evidence of the police surgeon or the judgement of the magistrate should be at fault in what is, in everyone's opinion, a matter of first-class public importance. I beg to submit herewith a few desiderata for your readers.

The time between the moment of arrest and of the accused being examined by the police surgeon should be as short as possible. Then, with the man's name, age, and address, he should be invited to tell his own story. If this is rational, and if there is no suggestion of incoherence of speech, disorder of behaviour, posture, and dress, or disorientation of time and place, then the fifteen to twenty tests commonly applied are unnecessary, for the man is not drunk at the time of examination.

As a rule magistrates prefer tests, and therefore it is wise to put the man through some of these, selecting the most striking results for the ear of the magistrate. The fact, however, that the condition termed "drunk" is due to alcoholic loss of guidance and control of the highest centres should be ever present to the mind of the surgeon during his examination, and, further, enable him in the witness-box to give his evidence in a manner that is lucid, calm, and decisive.—I am, etc.,

London, N.W.1, April 22nd.

J. MAUGHAN.

#### THERAPEUTIC USES OF OXYGEN.

SIR,—It was with considerable astonishment that I read the article on the cause and treatment of the crisis in lobar pneumonia in your issue of April 21st (p. 661). The author states that "In the past the use of oxygen has been the cause of more deaths in pneumonia than one cares to contemplate, simply because it was administered cold and not warmed to the required temperature. . . ." This sweeping statement is entirely unsupported by facts and is palpably incorrect. The small amounts of oxygen commonly used in many of the current non-quantitative methods of supposed oxygen administration are not sufficient to effect appreciably the temperature of the total volume of inspired air, and even with efficient quantitative methods the addition of, say, two litres per minute of oxygen would not reduce the temperature of the inspired air to any significant extent. On the other hand, good results have been obtained without oxygen in the treatment of pneumonia easing out of doors in cold dry air. Having had considerable experience of the administration of oxygen, both warmed and cold, in pneumonia and other conditions of oxygen lack, I can state dogmatically that warming *per se* makes little difference, and that provided that the method be efficient and the rate of oxygen flow adequate the results are excellent. Much more could be said regarding the facts of the case—it is sufficient, however, to protest rather against the manner in which so inaccurate a statement is made.

The final sentence also contains some amazing inaccuracies. Oxygen does not increase metabolism. Where the oxygen supply is insufficient for metabolic needs the animal rapidly succumbs from progressive oxygen lack. Experimental evidence clearly shows, however, that the metabolic rate is independent of the supply of oxygen provided that the latter be adequate (vide any textbook of physiology). The rationale of oxygen administration consists in increasing the oxygen percentage of the alveolar air sufficiently to overcome a pathological deficiency of permeability of the pulmonary epithelium and so to prevent or abolish oxygen lack. Oxygen does not destroy disease, although peroxides, in the absence of excess of catalase or peroxidase, accumulate in cultures of pneumococcus to an extent sufficient to inhibit the growth of the organisms. Efficient oxygen administration overcomes the pulmonary

functional deficiency and so prevents death and damage to tissues from oxygen lack before the immunity processes come into play. The final outcome depends upon those processes, whatever they may be.—I am, etc.,

Leeds, April 24th. H. WHITRIDGE DAVIES.

#### THE MEINICKE SYPHILITIC REACTION.

SIR,—In a report by Jambert et Gory (*Compt. rend. Soc. de Biol.*, 97, 1455-56) the reaction of Meinicke is stated to have permitted a definite classification as positive or negative in 91 per cent. of 610 syphilitic and 1,490 other serums. To quote from an abstract of this made by me (*Physiological Abstracts*, 13, p. 62, April, 1928): "The reaction is considered to be of great value in the battle with syphilis, and practitioners are advised to get it adopted in laboratories to which they look for diagnosis, or at least to insist on the simultaneous use of different methods." Though possessing little practical knowledge of the subject I venture to bring it to your readers' notice. Tolu antigen was used by the authors.—I am, etc.,

Physiological Department, University College, Cork, April 26th.

D. T. BARRY.

#### INVESTIGATION OF MATERNAL MORTALITY.

SIR,—The Council of the Society of Medical Officers of Health has had before it the letter appearing in the *Times* of April 3rd, over the signatures of certain obstetricians, as to the need for research into the above subject. The council is in agreement that the research required calls for a close alliance between the physician, the biochemist, and the bacteriologist, and the close apposition of the laboratory to the bedside, but it is not of opinion that an investigation by local health authorities of all maternal deaths should be excluded or discredited, and the council regrets that the signatories have seen fit to take this view.

The council would further put on record that the signatories are in error in suggesting that a knowledge of the cause of a disease is necessarily a *sine qua non* for its prevention, and in this connexion would refer to the control of small-pox by vaccination, the diminished incidence of enteric fever following on the betterment of sanitary and living conditions, and the reduction of deaths from scarlet fever as the result of the measures taken by health authorities.

The council of this society feels that matters of this kind are best discussed in the professional journals, and it therefore hopes that you will allow this reply to the letter referred to above to appear in your columns.—I am, etc.,

E. H. SKELL,

Acting President, Society of Medical Officers of Health.

London, W.C.1, April 22nd.

#### THE ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—My friend Mr. Back, in whom surgery has gained what has been lost to the Bar, has spoken admirably for many who feel as he does and have long suffered in silence. He deserves their thanks. The remedy is never to vote for any candidate on whose behalf his friends canvass, either in person or by letter. Others, I know, follow that rule, and are content to rely on their own judgement. Those Fellows who have no knowledge of the merits of the candidates had better abstain from voting. I understand from an unofficial but reliable source that the College authorities have long viewed canvassing with disapproval.—I am, etc.,

London, April 28th.

LIONEL COLLEDGE.

#### EFFECT OF THE BIRTH RATE ON THE AVERAGE AGE AT DEATH.

SIR,—There is another view of the question which Dr. J. H. Garrett's letter (April 14th, p. 644) discusses. The falling birth rate has been accompanied by a falling death rate, a rising average duration of life, and a rising average age at death, and all these phenomena have been closely correlated. This correlation, and its Malthusian significance, should not be ignored. While this correlation has continued—that is, while economic conditions have continued to be unsatisfactory—the diminution of the birth

rate has not been raising the average age at death for any other reason than the economic one. It has not been raising the average age at death in virtue of its other tendency, which Dr. Garrett stresses, to raise the average age of the population. This tendency can only be effective when the economic conditions of the older adults are not seriously depressed by the burden and competition of the young.—I am, etc.,

London, S.W.7, April 17th.

B. DUNLOR, M.B., Ch.B.

#### SUPERANNUATION OF MEDICAL OFFICERS.

SIR,—In reference to the report of the Departmental Committee upon the amendment of the Local Government and other Officers' Superannuation Act, the Ministry of Health must be well aware of the great importance of proceeding immediately to put the committee's recommendations into execution. There are various undesirable complications and hardships arising out of the present condition, especially in connexion with medical officers, partly due to the irregular application or refusal on the part of local authorities to apply Section 16 of the Act, which affects previous service. It would be lamentable if this Government went out of office without having brought the committee's recommendations to fruition by introducing a bill for this purpose during the present session.—I am, etc.,

April 12th.

ANOTHER VETERAN M.O.H.

#### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

ON April 30th the House of Commons discussed the Ministry of Labour vote, with special reference to the transference of miners to other areas and industries. On May 1st it resumed consideration of the Budget resolutions, and Mr. CHURCHILL announced that the Government had decided not to persist with the new tax on kerosene. This tax was accordingly rescinded, but no changes were granted in the new petrol tax. Discussion of the Budget continued on the following days.

The Parliamentary Medical Committee met at the House of Commons on May 1st, Dr. FLEMING presiding, and approved the arrangements for a visit, at the invitation of the Army Council, to Aldershot on May 4th to inspect military medical services and institutions. The committee discussed the National Health Insurance Bill. Dr. SINCLAIR made a statement on the position of national health insurance in Northern Ireland. The committee also discussed the schedules of additional benefits proposed in the bill, and decided by majorities to support the inclusion in the first schedule of three new benefits—the employment of specialists, professional attendance in childbirth, and medical attendance on the dependants of insured persons. Regarding the last proposal the committee was sharply divided, and its members felt that as the meeting was a small one its majority view should not be taken as a final one. No opinion was recorded on the proposal to allow other than medical benefits to the dependants of insured persons, this not being thought a subject for the Medical Committee as such. The committee passed a resolution to support an amendment to the National Health Insurance Bill on behalf of the dentists. This amendment would provide that the regulations for dental benefit should give free choice of dentist or clinic to an insured patient, and that no clinics should be run by approved societies. On the Budget the question was raised of whether a rebate could be secured on petrol used in doctors' cars for professional purposes. Sir RICHARD LUCE undertook to inquire as to the views of the British Medical Association on the subject, and the committee agreed that if the Association proved in favour of some such remission the officers of the Parliamentary Medical Committee, with Sir Richard Luce, should table an amendment to secure that remission. Other Budget topics were discussed and adjourned. It was announced that the chairman of the committee had put down a question for May 3rd asking the Minister of Health about the publication of the report of the Committee on Vaccination and Small-pox. The committee agreed to summon a special meeting after the issue of this report. It decided to say nothing concerning Mr. Briggs's Protection of Dogs Bill.

#### National Health Insurance Bill.

The standing committee of the House of Commons which is examining the National Health Insurance Bill resumed, on April 26th, its consideration of Clause 2, which amends the provisions of the principal Act concerning inmates of hospitals, etc. In response to a suggestion previously made by Mr. BRIANT, this clause was amended on the motion of Sir KINGSLEY WOOD to provide that a contributor leaving a hospital or institution should be permitted

to receive sickness or disablement benefit in a lump sum if the society or committee concerned thought that special circumstances warranted this. Dr. VERNON DAVIES asked whether payment would be allowed up to the maximum of £50. Sir KINGSLEY WOOD said it would.

Mr. HARNEY moved an amendment to provide that where any balance remained due to the insured patient it should be paid, not to the Central Fund, but to the institution, unless that were maintained by a public authority or out of public funds. Mr. HARNEY asked whether, when an inmate of an institution said he would like the balance to be paid to that institution, power already existed to have it so paid. Sir KINGSLEY WOOD said that was so.

Mr. HARNEY withdrew his amendment, and the committee carried the clause as amended.

Clause 3 makes amendment to the provisions of the principal Act on the administration of medical benefit, and proposes to enact that, after a date to be prescribed, no insured person other than a nurse or employee of an institution shall be allowed by an Insurance Committee to make his own arrangements for medical treatment or attendance by participating in collective arrangements through any system or institution. A proviso was added that any system or institution through which such arrangements had been made before March 6th, 1928, might apply to the Insurance Committee and to the Minister for approval.

Mr. JOHN opposed the clause, saying that the medical schemes or institutions in existence met the desire for a greater scope in medical treatment than could be given by individual panel doctors. Under the Act the individual medical practitioner was not called upon to have more skill than could be reasonably expected, but by the medical institutions under discussion medical treatments and benefits were so co-ordinated that members of the institution were entitled to get them from a number of doctors, both surgical and medical. These schemes also provided for electric treatment, massage, light treatment, and laboratory work from skilled doctors and surgeons. A number of doctors were engaged by these medical institutions. He had in mind one scheme which included 4,000 unemployed. If that scheme did not get further recognition those persons would be left without any medical service. Panel doctors could not be expected to take them over. He cited the progress of the Mid-Rhondda Medical Aid Society. In 1913 it was approved for about 800 members. Now it had practically 6,000 members, receiving medical treatment, medical appliances, surgical appliances, artificial limbs, dental treatment, and oculist treatment. No individual practitioner could provide these treatments.

Sir KINGSLEY WOOD said institutions for collective medical treatment of their members which were in existence at the passage of the National Insurance Act of 1911 were untouched by this new legislation. A number of institutions had been brought into existence which claimed to make dispositions so as to escape the normal arrangements of medical benefit. This had been done under the guise of making individual arrangements to receive treatment as provided by Section 15 (3) of the old Act—now 24 (3). When the Act was passed that provision was added to meet the case of the person who said, "I want to make arrangements with my own medical man." It was never contemplated that a number of people would be able to band themselves together and by a device put themselves in the same position as institutions existing at the passing of the Act. A number of these so-called institutions were under no obligation to render any returns to the department, which had no effective control to see that the standard of medical treatment was sufficient. In some cases this sort of society made a profit where there should be no profit, as all the money should be expended on behalf of the insured persons. Where, as the department thought, the payment to the doctor was not of a kind that ensured the best medical attention, the department was right in asking Parliament to intervene. It said that any of these institutions not coming under Section 24 (4)—that dealing with societies existing in 1911—must apply to the department, which would examine their claims sympathetically with the object of ensuring an adequate standard of treatment for their members. When approved they would have to supply proper returns to the department and generally conduct their institutions as the original institutions had been conducted. Each case would be considered on its merits.

Mr. JOHN said these schemes had to apply to the Insurance Committee for approval. The secretary of the Insurance Committee for Glamorgan had said before the Royal Commission that he had no cause of complaint against these schemes. The Mid-Rhondda scheme collected £7,218 last year, and the whole cost of administration was £100. It had seven doctors and paid them salaries higher than those in similar institutions recognized by the British Medical Association. Their efficiency and qualifications would compare with those of any other doctors in South Wales. This scheme had expended £4,000 on a proposed hospital for its members. Mr. JOHN added that he understood Sir Kingsley Wood to give an assurance that, subject to schemes being worked according to the standards of the Ministry of Health, no serious objection would be raised to their approval. That being so, he withdrew his objection to Clause 3.

Dr. VERNON DAVIES asked whether Sir Kingsley Wood's speech meant that future schemes on similar lines would be sanctioned. He would be much opposed to that. The old colliery clubs, which had now been called medical institutions, had done extremely good work, but he hoped no new ones would be allowed. The medical men associated with these schemes were competent and did extremely good work, but for some years now the British Medical Association had set its face against this type of institution or practice. Every week in the *British Medical Journal* a warning notice asked anyone applying for such a job to consult the Association first.

(Mr. JOHN: A ban!) When the present qualified and competent medical men retired the highest type of doctor would not apply for these appointments. (Mr. JOHN: We have got them.) Ultimately the institutions would have a type of medical man who, though fully qualified, was not the highest type of the profession, and the institutions would suffer. He hoped the Minister would not in any way sanction an extension of this system.

Sir KINGSLEY WOOD gave an assurance that the department had no intention of dealing with any but those systems and societies already in existence. They did not propose to deal with any new ones nor to encourage the practice.

Dr. WATTS said he did not approve of these institutions, but with the growing discontent in the country with the nature of the treatment people got under national health insurance, a number of people were anxious to band themselves together to make arrangements with private doctors under a system by which the Insurance Committees would hand over to them the capitation fee, and the patients would be willing to pay a supplementary fee to make sure that they got decent attendance as insured persons. He held no brief for the institutions or clubs under discussion. The medical attendance they gave was equally as bad as—if it were possible to be as bad as—the medical attendance under the national health insurance. He spoke from knowledge of the attendance which insured persons got under national health insurance. It was not the fault of the doctors. Under the National Health Insurance Act a doctor's time was taken up in a large measure by red-tape regulations and by keeping silly records which were of no use to anybody, and which, when they eventually arrived at the Ministry of Health, were, he understood, destroyed, no use being made of them. If certain groups of the insured population banded themselves together and made a private arrangement with medical men to attend them on the basis of the capitation fee plus some extra payment which they themselves voluntarily made, and that arrangement could not go on if this clause was allowed to remain, he agreed with the proposal to delete the clause.

Mr. RYAN DAVIES said Dr. Watts belonged to the Neolithic Age. Health insurance had come to stay, and doctors were now anxious to come into it, as payments were secure and they were much better off than in the days before the Insurance Act. He was not sure that people in South Wales were getting the best medical service. In some of these institutions the medical men were splendid fellows so far as their personality was concerned, and gained the confidence of the nation, but might not be competent medical practitioners.

Clause 3 was then approved.

Clause 4 proposed to permit approved societies and Insurance Committees, with the consent of the Minister, to make subscriptions and donations "of an eleemosynary character" to hospitals and similar charitable institutions, even although, in the case of the approved society, no disposable surplus was disclosed at the last preceding valuation. This was altered slightly at the suggestion of Sir Kingsley Wood to make sure that the clause did not bar new societies.

Mr. BRIANT moved to permit subscriptions to "hospitals, dispensaries, and other institutions." He thought the definition should be widened to cover future institutions with new methods of treatment, both preventive and remedial. Sir KINGSLEY WOOD said the clause endeavoured to end a system by which under the previous law advantage was taken to enter by way of contract with some institution, and in return to receive certain benefits for members of the society. That was perfectly permissible at the time, but in the opinion of many societies was detrimental to them. He must resist the amendment. All the societies should do in future was to make genuinely charitable gifts to institutions.

Mr. RYAN DAVIES said they should have in the Act some interpretation of what "charitable institution" meant. He gave a case where officers and committees of approved societies had formed themselves into a "charitable institution," and another where an approved society decided to establish a clinic from funds granted under the same pretext. All money spent from national health insurance funds by Insurance Committees and approved societies should be audited to its destination. By subterfuges societies had been able to detach money from their benefit funds to provide additional benefits which they could not, in law, provide.

Mr. MILLER said some societies had used this section to offer additional benefits in anticipation of a surplus which they had no reason to assume would come to them, and in order to attract people to their societies. If that could be stopped it would be desirable. The Revenue would recommend that gifts should be made to surplus, but this bill went except out of a guizing that there were cases where some gift might be made to an institution whereby special treatment could be obtained.

Dr. DRUMMOND SMITHS said he was interested in the section as connected with the important subject of specialist benefit. The committee had heard speeches showing the unsatisfactory character of the present medical benefit under the Insurance Act. Societies in the past had tried to make arrangements with voluntary hospitals that in return for a donation a certain number of beds would be reserved. In many cases that arrangement had been refused, as managers of voluntary hospitals had not felt they were entitled to make such allocations. He asked whether an arrangement with a voluntary hospital for a certain number of beds to be set aside for a particular approved society would be allowable under the clause.

Sir KINGSLEY WOOD said Dr. Shiels would have an opportunity of raising that on another part of the bill.

Dr. SMITHS asked if a voluntary gift could be accompanied by any condition as to the treatment of an individual or of a number of individuals.

Sir KINGSLEY WOOD said the gift would not then be voluntary. Dr. FRENCHAMPTON pointed out that the clause in the bill omitted the provision in the original Act that gifts might be made for the support of district nurses or for the appointment of nurses to visit and nurse insured persons. Were district nursing associations, Queen Victoria Jubilee Nurses, and midwives' societies intentionally omitted, or were they included under the words "similar charitable institutions"? Contributions to such institutions under Section 25 of the old Act had been very useful and much desired by the people. Nothing should be taken away which might help in reduction of maternal mortality.

The CHAIRMAN (Mr. William Nicholson) pointed out that the next amendment dealt with the words "and similar."

Mr. BRIANT withdrew his amendment.

Mr. HARVEY moved to leave out the words "and similar," and to insert instead "dispensaries and other."

Sir KINGSLEY WOOD said he desired to give an assurance that the Ministry did not wish to rule out any charitable gifts of such a character as those to a district nursing association.

Mr. HARVEY's amendment was accepted by the committee.

Dr. FRENCHAMPTON moved to add to the purposes for which approved societies might make gifts "or for the training or support of district nurses or midwives, and may appoint nurses or midwives for the purpose of visiting and professionally attending insured persons."

Sir KINGSLEY WOOD said the amendment was inappropriate at that stage, and he could not then accept it.

Mr. RIVS DAVIES trusted the committee would not accept the amendment. All the money paid into the funds of approved societies should be paid to approved persons, doctors, dentists, opticians, surgical appliance makers, hospitals, nursing institutions, were all after this money.

Dr. SHULLS said many of the institutions for training midwives and nurses were supported from charitable donations, and many were in an unsatisfactory condition. There was not a sufficient supply of midwives for the wives of insured people. The amendment emphasized the principle that the wives of insured persons should have adequate and efficient nursing, and that an approved society should be able to give donations to societies which were training people for that work.

Dr. FRENCHAMPTON withdrew his amendment, and Clause 4 was added to the bill.

The committee then discussed Clause 5, amending the provisions of the principal Act concerning the repayment of benefits improperly paid. Sir KINGSLEY WOOD accepted an amendment providing that the repayment should not exceed 3s. 9d. a week, and the clause was then carried.

Discussion followed on Clause 6, making administrative provisions regarding societies with members in more than one national area, and the committee adjourned till May 1st.

Consideration of the bill was resumed on May 1st. On Clause 6 Mr. JOHNSTON moved an amendment to provide that where a society without branches had been approved for more than one national area a separate valuation might be made in respect of each national area. He said he proposed this because of the large excess of expenditure on sickness in Northern Ireland, as revealed by the experience of the Prudential and other approved societies. Dr. VERNON DAVIES asked why there was this excess. Mr. JOHNSTON said it was due to the different method in which doctors approached the question. Test examinations in Northern Ireland had disclosed that persons had been continued in benefit who would not have been so continued in Great Britain.

Colonel SINCLAIR, who was indistinctly heard, resisted the amendment. Any excess of sickness was due to the fact that Ulster had a poor agricultural population. The Government of Northern Ireland contemplated future action with regard to health insurance.

Mr. CHAMBERLAIN said there was power under the existing Act by regulation to form a separate society for Northern Ireland and to transfer members to it from the parent society. They would have to secure the consent of the members in Northern Ireland. The proportion per head of sickness benefits was high, but in total payments the amounts were trivial. He understood that the Government of Northern Ireland was unable at the moment to assimilate its national health insurance system to that in this country.

Dr. VERNON DAVIES said he had never met people who were more afraid of sickness or pain than the Irish people. At the slightest pain they ran for the doctor, and the second question was, "Shall we send for the priest?" That psychological attitude—the fear of death on the slightest pain—must be kept in mind.

Mr. MELLER said that if medical benefit were introduced in Northern Ireland, where at present the dispensary service was an inadequate substitute, there would be an increased disparity in contributions between Northern Ireland and the Irish Free State. Mr. RIVS DAVIES asked whether the Minister would press the Government of Northern Ireland to set up an inquiry into the provision. Mr. CHAMBERLAIN said that would be very difficult to do. Representations could only be made through the Secretary for the Dominions.

The committee divided on Mr. Johnston's amendment, which was defeated by 12 to 26. Clauses 6 and 7 were then added to the bill.

Clause 8 authorizes the Minister, under regulations, in any case in which he has reason to believe that the affairs under this Act of an approved society are not properly administered in any respect to cause an inquiry to be held into the administration of the affairs of the society, and if he is satisfied as a result of the inquiry that the administration should be improved, and the society fail after such period as he may determine to introduce such reforms into the administration as are necessary, to order the amount which may be carried to the administration account of the society out of contributions under this Act to be reduced by such sum as he may direct.

Mr. WHITELEY moved an amendment providing that before making such an order the Minister should appoint an independent body to investigate and report on the affairs of the society.

Mr. CHAMBERLAIN said the proposal in the clause was much less drastic than the present law, which made withdrawal of approval, without inquiry, the penalty for maladministration by a society. Clause 7 already provided for an inquiry, and Mr. Whiteley's proposal was superfluous.

Sir KINGSLEY WOOD said it could be generally said that the administration of the societies under a complex Act of Parliament had been creditable to all concerned. Since 1911 there had been about thirty cases of maladministration, which had been met by arranging that the members of the societies concerned transferred to more efficient ones.

Mr. WHITELEY withdrew his amendment. Clauses 8 and 9 were added to the bill.

Clause 10 provides that deposit contributors who are debarred by their state of health from membership of an approved society may apply to the Minister for admission to a deposit contributors' insurance section. Mr. HARVEY moved the omission of the conditions that the application must be made within a prescribed time, and that the exclusion must have been for reasons of health.

Mr. CHAMBERLAIN said the clause was in accordance with the recommendations of the Royal Commission on National Health Insurance. No real difficulty would arise. Mr. HARVEY withdrew his amendment.

During further discussion on the clause Sir KINGSLEY WOOD said it was desirable to draw the conditions of membership for the deposit contributors' section so as to prevent the setting up of a great State insurance section in rivalry to the self-governing approved societies. Ill health was a condition of membership of the section, and any contributor who made no claim for two or three years would be asked to try and secure membership of an approved society.

Clause 10 was added to the bill.

Clause 11 proposes amendments in the provisions of the principal Act dealing with sickness and maternity benefit for unemployed married women. This was added to the bill without discussion.

Clause 12 provides for the establishment of a Seamen's Special Fund, and for the use of contributions payable in respect of masters and seamen neither domiciled nor having a place of residence in the United Kingdom. Masters and seamen are to be eligible for benefits out of this fund, whether they are insured persons or not. The committee assented to this, and to Clause 13, thereafter adjourning till May 3rd.

#### Small-pox.

Sir KINGSLEY WOOD, replying to Mr. LANSBURY, on April 24th, said that in the twelve months ended March 31st 51 cases of small-pox were notified in London. There were 7 cases of small-pox during this period amongst homeless persons in London; but information was not available as to the number of persons who had been in contact with those cases and who subsequently either developed small-pox or escaped infection; 13,348 cases were notified in England and Wales during the period in question. Complete particulars as to the vaccinal condition of these cases were not available. During the same period small-pox was entered on the medical certificate as the cause, or one of the causes, of death in 66 instances. The figures quoted above were, of course, provisional.

In an answer to Mr. Kelly, on April 26th, Mr. CHAMBERLAIN said Circular 830 dealt with the detection of small-pox among casuals, and advised boards of guardians that if a case of small-pox was found in a casual ward the temporary closing of the ward should not be necessary if certain precautions were taken. The circular did not deal with the permanent closing of redundant casual wards. He would soon speak about the extent to which his views on casual wards and small-pox had been accepted by boards of guardians.

On May 1st Sir KINGSLEY WOOD told Mr. Grundy that circular letters were recently issued to boards of guardians in consequence of the epidemic of small-pox. Apart from these, no special instructions had been issued, but the guardians were fully aware of the regulations in force, and the officers of his department would, as occasion might require, draw their attention to any necessary improvements in the arrangements of the several casual wards. As at present advised, the Minister of Health saw no ground for further action on his part.

#### Maternal Mortality.

Sir KINGSLEY WOOD told Sir Robert Thomas, on April 25th, that Mr. Chamberlain proposed to appoint a special committee on maternal mortality. The committee would doubtless report whether further financial assistance could usefully be provided for research into the question.

On April 26th Mr. CHAMBERLAIN told Sir Basil Peto that a detailed classification of deaths due to pregnancy and child-bearing was not available for a later year than 1925, in which there were 84 deaths from septic peritonitis, perimetritis, and pelvic peritonitis. It was a duty of doctors at ante-natal clinics to detect and remedy any focus of infection which might later be a cause of septic infection.

Sir BASIL PETO asked whether Mr. Chamberlain did not know that septic peritonitis almost always supervened from attempted abortion, and whether that was not brought about by the policy of the Ministry of Health in denying information about birth control at maternity and welfare centres.

Dr. VERNON DAVIES asked how anything which was done at an ante-natal centre could get rid of septic peritonitis.

Commander KENWORTHY asked whether Mr. Chamberlain denied that his policy, which the House had approved, of refusing Government information on birth control was responsible for these infections.

Mr. CHAMBERLAIN denied it. On Mr. THURTELL reasserting that lack of information about restriction of families did cause these cases, the Speaker intervened, saying such controversial questions could not be pursued at question time.

#### *Tuberculosis in England and Wales.*

Mr. CHAMBERLAIN, answering questions put by Captain Bournie on April 26th, said that on December 31st, 1927, there remained on the registers of local authorities in England and Wales 363,187 notified cases of tuberculosis. Excluding general hospitals, 215 institutions approved by the Ministry of Health for the residential treatment of tuberculosis had been approved by local authorities in England and Wales, and 134 by voluntary bodies. All these were maintained wholly or in part out of public funds. He had no complete information about institutions not so maintained. Details of the number of persons receiving treatment for tuberculosis in sanatoriums during 1927 were not yet available. In 1926 the number of persons who received residential treatment for tuberculosis under the schemes of local authorities was 63,680, the average duration of treatment being approximately 150 days.

Sir KINGSLEY WOOD, on April 24th, told Mr. Hore-Belisha that it would be impracticable to obtain accurate or complete statements as to the percentage of the industrial employed population who were discharged from their work in 1927 because they were suffering from tuberculosis.

#### *Foot-and-Mouth Disease.*

Mr. GUINNESS, answering questions on April 30th, said that during April one fresh infected area was declared on account of an outbreak of foot-and-mouth disease at Selston (Notts). Three outbreaks were confirmed in areas in which restrictions were in operation at the end of March on account of previous outbreaks. The discovery of the Foot-and-Mouth Disease Research Committee that the virus of foot-and-mouth disease remained alive in the marrow of bones for a considerable period led to the prohibition of the import of bone and bone products from the continent of Europe. Manures of animal origin were admitted under licences, subject to certain conditions.

On May 1st Mr. GUINNESS informed Sir H. Hope that the Foot-and-Mouth Disease Research Committee was investigating the behaviour of foot-and-mouth virus in animal products and on inanimate objects, in the hope of discovering the means by which the virus was introduced to this country and methods of excluding it.

#### *Bills.*

A bill to amend the Rag Flock Act (1911) was presented on April 25th by Mr. Mackinder, supported by Dr. Vernon Davies.

A bill to provide for the representation of the University of Reading in Parliament was presented by Mr. Somerville on April 26th.

The Bethlem Hospital Bill was read a second time in the House of Lords on April 19th, and sent to committee.

On April 26th the Protection of Dogs Bill, introduced by Mr. Briggs, was read a second time. An amendment, subsequently tabled to the bill by Mr. Briggs, proposes to throw on all finders of stray dogs a legal obligation to hand them over to the police.

*Treatment of Venereal Disease in Scotland.*—Sir J. GILMOUR, in reply to Mr. Buchanan, on May 1st, said that while in certain counties in Scotland there were no centres for the treatment of venereal disease, there was no county in Scotland without facilities for such treatment, either at a centre situated within its borders or by arrangements with another local authority. With regard to towns of a population of 10,000 and over, the position was as stated in his reply of April 17th. He was aware that a certain number of persons suffering from venereal disease might shift from place to place, and, indeed, for one important class of persons who frequently moved—namely, sailors—treatment facilities had been specially provided in the principal ports. The development of venereal disease schemes in all areas was being carefully watched and reviewed by the Scottish Board of Health. He did not think that at present any good purpose would be served by the appointment of a committee of inquiry such as Mr. Buchanan had suggested.

*Medical Appointments in Palestine.*—In an answer to Mr. Kelly, on April 25th, Mr. AMERY said that as yet no Government medical appointments in Palestine were open to women doctors. The special positions for dealing with infant welfare which ordinarily were filled by women doctors were covered in Palestine with a widespread service of nurses and midwives. In the opinion of the Government there was no special opening in Palestine for women doctors in other capacities.

*Sleeping Sickness.*—Mr. AMERY, in reply to Sir R. Thomas, on April 30th, said that his attention had not been drawn to the appointment by the Lisbon Government of a commission to investigate the causes of sleeping sickness in Mozambique, with special reference to the tsetse fly. He would, however, ask the Secretary for Foreign Affairs to make inquiry in the matter. A number of such missions, including several in our own territories, were engaged in the investigation of sleeping sickness problems in Africa, and endeavours were made, through a subcommittee of the Committee of Civil Research, to ensure effective collaboration among workers engaged in the study of sleeping sickness.

## Obituary.

SIR WILLIAM SELBY CHURCH, BT., K.C.B., D.M.,

Consulting Physician to St. Bartholomew's Hospital; President of the Royal College of Physicians of London 1899-1905.

THE death, on April 28th, of Sir William Church in his ninety-first year removes a great figure in the medical life of this country at the end of the last and the beginning of the present century. As he retired from St. Bartholomew's under the 65 years' age-limit as long ago as 1902, he was personally little known to the present generation; but such an example of an English country gentleman with simple sportsmanlike instincts guiding a long professional life has seldom been so consistently and unobtrusively set before men. In his time he bore much of the brunt of directing the policy and the activities of many important bodies, such as the great medical school of St. Bartholomew's Hospital, the Royal College of Physicians of London, the Royal Society of Medicine, the Imperial Cancer Research Fund, and the hospital funds of London.

William Selby Church was a member of an old and long-lived family. His father, John Church, J.P., D.L., who was born in 1782 and died in his eighty-ninth year, was taught to shoot by a man who had shot snipe along the River Fleet. His mother was Isabella, daughter of George Selby of Twizell House, Northumberland, and came of a family which once owned most of Northumberland and were the hereditary janitors of Berwick. His maternal grandfather, Pridemore John Selby (1788-1867), High Sheriff of Northumberland in 1823, was a well-known field naturalist, and painted for his illustrations of *British Ornithology* (1825-34) life-size pictures of the birds, some of the originals being in Sir William's possession. William was the youngest of three sons, the other two dying comparatively young, and was born on December 4th, 1837, at Woodside, the house in which he died, on the borders of Hatfield Park. He remembered travelling to Eastbourne when the railway from London went no further than Tunbridge Wells, where the coach had to be taken. He went to Harrow, then under Dr. C. J. Vaughan, in 1851, and was in the school eleven for four years (1853-56), being captain in his last year; but being then overgrown and short of breath he was forbidden by Dr. Richard Bright to play, and accordingly resigned his captaincy. There was, however, no regular match at Lord's against Eton that year, or indeed in 1857, because the headmasters disagreed about the date, Vaughan, indeed, vetoing the match during term time; but in the latter year he played at Lord's for eleven Harrovians under 20 years of age, including those at the universities, against eleven similar Etonians. He often represented Oxford, but did not get his "blue," and continued to play until, in village cricket, he met with the accident so familiar to athletes getting on in years—so-called rupture of the plantaris tendon. As a small boy at Harrow he heard the conversations of Old Harrovians, friends of his father, who remembered and spoke of Lord Byron in not very complimentary terms.

He went up to University College, Oxford, in 1856, and in 1860 took a first class in the School of Natural Science. In this year he was appointed Lee's Reader in Anatomy, thereby becoming a student of Christ Church, and held it until 1869, when residence was made obligatory. He entered at St. Bartholomew's Hospital Medical School probably about 1861 (for examination of the students' register does not show his signature), and worked at morbid histology with James Andrew, then warden of the college, at whose suggestion he investigated, in 1862-63, with J. S. Warter, clinical thermometry and the distinction between typhoid and typhus fevers by means of holding a rod dipped in hydrochloric acid and getting fumes in typhus cases. Warter, who was M.D. of Edinburgh, contributed a paper on "The thermometer in disease" to the *Hospital Reports*, but died prematurely of typhus. Church took the B.M. in 1864, and the D.M. Oxon. in 1868, the membership of the Royal College of Physicians in 1864, and in 1870 was elected a Fellow, together with his junior colleague Dyce Duckworth, who also died this year; since 1923 he had been the senior Fellow of the College. He lectured on comparative anatomy at St. Bartholomew's, and was

physician to the Royal General Dispensary in Bartholomew Close, and assistant physician to the Victoria Park Hospital for a time. In 1866 he was put in charge of the cholera wards at St. Bartholomew's Hospital, and then for three months was acting apothecary for Mr. Wood, thus doing the work subsequently discharged by house-physicians; in March of the following year (1867) he was elected assistant physician, and continued to do much work in the post-mortem room, publishing papers on cerebral pathology and aneurysms in the *Hospital Reports*. Between 1868 and 1880 he made thirty communications to the old Pathological Society of London, all but two before 1874. Early in 1875 he became full physician to the hospital, and when he was elected consulting physician in 1902 had taught no fewer than forty-six house-physicians. As a general physician—a type now becoming exceptional—Church was extraordinarily sound; one of his former house-physicians, who has since followed in his footsteps in being physician at their old hospital, recently expressed doubt if he ever made a serious mistake in diagnosis. He taught more by example than by precept, and had a shrewd eye to the main issues, rather avoiding extreme refinements of diagnosis. Long apprenticeship in the post-mortem room, or, as he usually called it, the dead house, had given him a sense of due proportion, and this experience he increased by constant visits when full physician. His house-physicians learnt more from him than did those who were mainly concerned to pick up hints thought to be useful in steering them safely through the jaws of the examining bodies. He certainly never "laid himself out for practice," and his voice was not heard in the market-place; but, though he gave no sign of disappointment, he was not so indifferent to private practice as was commonly supposed.

At the Royal College of Physicians of London he held the offices of Examiner in 1874, 1875, 1884-86, Councillor 1888-89, Censor 1890-91, Senior Censor in 1896, and was elected President 1899-1904. The first election, on March 27th, 1899, on the retirement of the late Sir Samuel Wilks, was remarkable for the close contest between him and the late Sir William Broadbent, and was impressed indelibly on the memory of those present by the sudden failure of the electric light, which necessitated the votes (Church 77, Broadbent 67) being counted by the glimmering light of a single lamp—a Rembrandt-like effect.

Throughout his life he shouldered laborious and necessary, but not invariably interesting, tasks as a matter of duty without any suggestion that this was the reason, and, moreover, always mastered the business thoroughly. At the Hospital School committees he was indefatigable, and was said to have carried the staff on his back. On the General Medical Council he represented the University of Oxford from 1889 to 1898, and on Sir Henry Acland's resignation of the regius professorship of medicine in 1894 was his obvious successor, but for family reasons he declined to be put forward. When he became President of the Royal College of Physicians of London official appointments crowded upon him. In 1900 he went to South Africa as a member of the Royal Commission on the Treatment of the Sick and Wounded in the South African war. On the announcement of this Commission there were some questions

asked in a critical tone in the House of Commons about some of the members of the Commission, and in answering them Lord (then Mr. A. J.) Balfour showed up their futility by adding, "I suppose that someone will express doubt about Dr. Church's appointment?" In 1901 he served on the Royal Commission on Arsenical Poisoning by Beer in the Midlands, and in 1906 was on the Royal Commission on Viri-section. He was chairman of the executive committee of the Imperial Cancer Research Fund from its foundation in 1902 until July, 1923. He took an active part for many years (1903 to 1918) as chairman of the distribution committee of the King Edward VII Hospital Fund for London, and was also chairman of the distribution committee of the Hospital Sunday Fund until 1922. As President of the Royal College of Physicians he was naturally called upon to give introductory addresses; in October, 1901, he delivered the address at the opening of the winter session

at the Yorkshire College, Leeds; at the Oxford Meeting of the British Medical Association in 1904 he gave the Address in Medicine on "Our sanitary needs, with special reference to the national health"; and, in 1905 he addressed the York Medical Society on "Medicine in the past, present, and future." When Sir Andrew Clark, who was president of the Royal Medical and Chirurgical Society, died in November, 1893, Church was the senior medical vice-president; and accordingly acted as president for the remainder of the session—by no means a light task, for it involved the preparation of the president's address, chiefly composed of detailed obituaries of deceased Fellows, which (and particularly in the case of Sir Andrew Clark) necessitated many and minute inquiries. In 1884 he became one of the honorary treasurers of the society, and in 1905, when senior honorary treasurer, directly after ceasing to be President of the Royal College of Physicians, became chairman of the organizing committee, which, after two years of constant negotiations, successfully accomplished the amalgamation with seventeen other medical societies into

the Royal Society of Medicine in 1907, of which he appropriately became the first president. The enormous labour of conciliating and satisfying the wishes and rights of the contracting bodies had been unsuccessfully attempted several times before—for example, in 1870, when the number of interests concerned was very much smaller. This eventual success, for which the honorary secretaries—the late Dr. Arthur Latham and Mr. H. S. Pendlebury—and the late Sir John MacAlister played admirably in team work, owed much to Sir William Church, for he was, as Sir William Osler said when seconding his election as president, "that rare bird in the profession, a good business man." He continued the honorary treasurership during his presidency (1907-09) until 1913 (except for the year 1911), thus steering the financial course of the society through the troubled waters of finance during the most critical years of transformation and early growth.

Church was not a voluminous writer, but whatever he did, and usually it was in response to some special call, was the outcome of much work and solid thought. He delivered the Harveian Oration at the Royal College of Physicians of London in 1895, the year after Sir Lauder Brunton, who for years was his corresponding assistant

[Elliott and Fry.

SIR WILLIAM CHURCH, Bt., K.C.B.

physician. His Harveian Oration on "The rise of physiology in England" was supplemented by an appendix in small print occupying rather more than half the number of pages that the Oration itself did, and containing much interesting detail, the outcome of patient research. He was Editor of *St. Bartholomew's Hospital Reports* for a number of years (1877 to 1893), bringing out the thirteenth to the twenty-ninth volumes inclusive, and a large part of what he wrote on purely professional subjects is embedded in their pages. He contributed to the first volume a paper on ichthyosis with congenital malformation of the aorta, and for the last time, in 1897, accounts of clinical cases from his wards. The thirteen papers between these two cover a wide range of medicine, as is shown by reference to some of them, such as his report on 136 cases of cholera with 44 deaths, or 33.08 per cent., treated in the hospital in 1866; two valuable reports on cerebral pathology, in 1868 and 1869; a discussion on the etiology of aneurysms (1870), on pyæmia (1893), diphtheria (1891), hydatids (1893). A most important contribution was his analysis of nearly 700 cases of rheumatic fever (1887), on which he wrote with authority in the first and second editions of Allbutt's *System of Medicine*. A great deal of time-consuming and exhaustive investigation was entailed in his historical account of "Our hospital pharmacopœia and apothecary's shop," and in an appendix to the first instalment "A note on the six gifts of Theophilus, Philanthropos or Robert Poole." (The "gifts" of Robert Poole, physician to the Middlesex Infirmary and the Small-pox Hospital, and a follower of George Whitfield, were published works, of which the fifth was the *Physical Vade Mecum*.) He also wrote obituary notices of his colleagues James Andrew and Sir Thomas Smith. In 1899, in an address to the Abernethian Society of the hospital, he reviewed "The progress of medicine during the reign of Queen Victoria," a period then almost corresponding to his own life.

Many honours, entirely unsought, rightly came to him; he was created a baronet in 1901 and K.C.B. (Civil) in 1902, an Honorary Fellow of University College, Oxford, and an Honorary D.Sc. of that University in 1904; he was also the recipient of the Honorary D.Sc. Victoria, D.C.L. Durham, and LL.D. Glasgow. He was a keen shot, fond of horses, and was at one time a prominent member of the London Skating Club. He travelled little abroad, as he had many interests in his country home, where after his retirement he was active as a county councillor and justice of the peace, and in other respects.

Tall, handsome, and with a fine presence, his features when at rest were serene and of a natural unconcealed dignity, but they did not invite any attempt to dictate; bluff, or override his opinion, which he always gave quite plainly. Surprisingly modest, without diffidence or shyness, he was firm, but never showed anger, and was absolutely devoid of self-seeking or log-rolling; he was indeed a just man, whose impartial decisions and wise advice inspired general respect and confidence. Kind and hospitable, he naturally had numerous friends in different walks of life; and among the profession he served so well there are many who owe him much for generous help, and even more for a wonderful example.

In his early professional life he lived first in Granville Street, Portman Square, then at 2, Upper George Street, Bryanston Square, and all his married life at 130, Harley Street. In 1875 he married his relative Sybil Constance, daughter of C. J. Bigge of Linden, Northumberland, who was an uncle of Lord Stamfordham. Lady Church died suddenly in 1913, leaving one daughter and two sons, the elder of whom, John William, was killed in the war (1918), and the younger, Major Geoffrey Selby Church, M.C., R.F.A., succeeds to the title.

The funeral took place on Monday, April 30th, at St. Mark's Church, Woodhill, near his home. A memorial service was held at the same time at the Church of St. Bartholomew the Less inside the precincts of the hospital with which he had been connected for sixty-seven years. It was attended by the President, Censors, and Officers of the Royal College of Physicians.

HUMPHRY ROLLESTON.

## PERSONAL APPRECIATIONS.

We are indebted to Sir ARCHIBALD GARROD for the following appreciation:

The death of Sir William Church, at the ripe age of 90 years, removes from amongst us the Nestor of the Oxford Medical School and the last survivor of a generation of physicians and surgeons to St. Bartholomew's Hospital who seem, to those who were taught by them, to have included an unusual number of men of outstanding personality. For Oxford Sir William had strong affection from the days of his youth when, having taken a first class in the Honour School of Natural Science, he was for a time Lee's reader in anatomy and a senior student of Christ Church. At a later period he represented the University on the General Medical Council, and served on the Board of the Faculty of Medicine. He always had the interests of the Oxford Medical School near to his heart. At St. Bartholomew's he is chiefly remembered as a wise counsellor, whose advice always reflected his own high standards, and always courteous and considerate to those with whom he came in contact. He was also a very able administrator, and his colleagues testified how much of the success of the Medical School was due to its treasurer. These qualities found even wider scope during the six years of his presidency of the Royal College of Physicians. By birth and tastes a country squire, and fond of country pursuits, Sir William devoted his best energies to any work in committee room or ward which he undertook. No one was more regular in attendance, and although he was not at his best as a clinical teacher, one recalls consultations in which he alone reached a correct diagnosis, and sentences which summed up tersely all that needed to be said on a subject. His friends and pupils rejoiced that he was able to enjoy the evening of his life, spent in his country home in the surroundings which he loved so well.

Dr. H. MORLEY FLETCHER, senior physician to St. Bartholomew's Hospital, writes:

As one who served under Sir William Church, first as a clinical clerk and later as his house-physician, and afterwards had the privilege of enjoying his friendship for many years, I am glad to have an opportunity of contributing a few lines about his work at St. Bartholomew's Hospital. His fine presence; his bushy eyebrows, and his keen, penetrating dark eyes with their kindly expression made him a most impressive figure in the wards. He did not give bedside addresses but said comparatively little, though he always liked to be questioned by his clerks, and then he would talk freely in reply. As a teacher he was perhaps more valuable to his house-physicians than to students. During his twenty-eight years of office as physician he had forty-six house-physicians, and all of those who acted in that capacity felt that they owed him a great debt of gratitude for his sound teaching in clinical medicine. His power of diagnosis was very striking, and rarely, if ever, was it found to be mistaken. It was always based on a most thorough physical examination, and never did he attempt a diagnosis based on insufficient grounds. He was a fine morbid anatomist, and for years performed the medical post-mortem examinations at the hospital. The records so carefully drawn up by him are evidence of his devotion to this important department of medicine. He was a pillar of strength on the medical staff, as he was indeed a wise counsellor. His honesty of purpose, strict impartiality, and sound judgement were recognized and valued by all his colleagues. As chairman of the Finance Committee for many years he played a great part in building up the school on a firm basis. After his retirement from active service on the staff he served on lay committees to the great advantage of the administration of the hospital.

What one could always feel with Church was that in him one had a wise friend of great experience and judgement, to whom in times of doubt or trouble one could always go for advice and help, and that this would be forthcoming in full measure. I think he was the most honest and truthful man I have ever had the honour of knowing.

J. A. MACDONALD, M.D., M.Ch., LL.D.,  
Past Chairman of Council and of the Representative Body,  
British Medical Association; Consulting Physician,  
Taunton and Somerset Hospital.

IN our last issue we had to announce with deep regret the death of Dr. J. A. Macdonald, which took place on April 23rd at his home in Taunton, after an illness of some months' duration. In him the British Medical Association loses one of its great figures, a man of outstanding character, universally liked and respected, who devoted a very large part of his working life to the interests of the medical profession and the welfare of his brother practitioners.

James Alexander Macdonald was born in 1855 at Newtownards, County Down, and on leaving school studied for the teaching profession. From his earliest days he was a fine athlete. He played for Ireland in the second International Rugby football match against England, and was in the Irish team for several years; he also played in one international Association match against England, and was an international lacrosse player along with his three brothers. After a short time as a schoolmaster at the Methodist College, Belfast, he decided to take up the profession of medicine, and entered as a medical student at Queen's College in that city, graduating M.D. and M.Ch. at the old Royal University of Ireland in 1887, and B.A.O. in 1889. To a man of Macdonald's open-air tastes and splendid physique the life of a country practitioner naturally appealed. On coming to England some forty years ago as assistant to the late Dr. George Cornish of Taunton, he soon became identified with the public life of the town and district. He succeeded to Dr. Cornish's practice, became medical officer to the Taunton Board of Guardians, and was appointed to the staff of the Taunton and Somerset Hospital, which he served for many years as physician, though surgery was perhaps his strongest professional interest. He took a keen interest in politics, both general and local, and was for a long time chairman of the old Taunton Conservative Association. Ever ready to encourage sport in his adopted town and county, Macdonald's services were in constant demand at athletic meetings of all kinds. He was a very familiar figure on the county cricket ground at Taunton, and maintained his interest in Rugby football up to the last.

In the British Medical Association, which he served with

such ability and distinction, Macdonald held almost every office. He had been a member of the West Somerset Branch Council from 1894 onwards, and had acted as its representative for the past twenty-five years, holding office as president of the Branch in 1899 and again in 1926. In recognition of his work for the profession in the West of England he was elected an associate member of the Dorset and West Hants Branch. He became a member of the Central Council in 1906, and soon afterwards was elected Chairman of the Representative Body in succession to Sir Victor Horsley. He held this post for three years, and was then chosen to succeed Mr. Edmund Owen as Chairman

of Council. He retired from that position in June, 1920, after serving for ten arduous and eventful years, which included the Insurance Bill crisis and the whole period of the war. He was elected a Vice-President of the Association at the Belfast Annual Meeting in 1909, held office as President of the Section of Medical Sociology at the London Meeting in 1910, and during the Birmingham Meeting in 1911 received the honorary degree of LL.D. from the University of Birmingham. The Association's Gold Medal of Merit was awarded him in 1913. In the following year he made a tour of the New Zealand, Australian, and some of the Far Eastern Branches, and he acted again as ambassador of the parent body to Oversea Branches when he visited South Africa soon after relinquishing the chairmanship of Council. These visits were greatly appreciated by all members of the Branches, and they did much to bind closer together the British Medical Association at home and overseas. Dr. Macdonald's absence in South Africa during the latter part of 1920 was taken as an appropriate moment to set on foot an appeal for

*J. A. Macdonald*

a testimonial fund in acknowledgement of his long and self-sacrificing work for the Association and the profession; the presentation was made to him during the Newcastle Annual Meeting by Sir Clifford Allbutt, the outgoing President. From 1920 onwards Macdonald was chairman of the Journal Committee; this was work which made a strong appeal to him, and he was admirably equipped for it by temperament and experience. His loyalty to the *Journal* and its staff was made plain to all every year when he presented the Committee's report to the Representative Body.

For the past seventeen years Macdonald had been one of the direct representatives of the profession in England and Wales on the General Medical Council, and during a considerable part of that period he was a member of the

Executive Committee and of the Education Committee. He was diligent in attendance at Committee and Council meetings, and took a deep interest in the disciplinary business. Another proof of the trust reposed in Macdonald by his fellow practitioners was their choice of him to preside over the early sessions of the Conference of Representatives of Local Medical and Panel Committees. In October, 1919, he was appointed by Dr. Addison (the first Minister of Health) as a member of the Consultative Council on Medical and Allied Services. Lastly may be mentioned his presidency for several years of the Irish Medical Schools' and Graduates' Association.

The funeral, on April 26th, was very largely attended—indeed, the whole of Taunton seemed to have turned out to the church service, and a large number of the townspeople walked to the cemetery. There was a big attendance of Freemasons, Dr. Macdonald having been a very prominent local Freemason, and also a Past Grand Officer. The medical profession was well represented. The Chairman of Council (Dr. Brackenbury) and the Medical Secretary (Dr. Cox) represented headquarters, Drs. F. J. Gomez and H. C. Bristowe represented the Council as well as the West Somerset Branch, and Dr. D. E. Finlay the Gloucestershire Branch. Two other colleagues and old friends must be mentioned—Drs. A. E. Joselyne and J. T. Cameron, who had attended Dr. Macdonald during his last illness.

#### PERSONAL TRIBUTES.

We are indebted to a number of leading old colleagues and friends of Dr. Macdonald in the work of the British Medical Association for the personal appreciations that follow.

Sir JENNER VERRALL writes:

It is told that, when Coleridge died, Charles Lamb would recall his loss from time to time and suddenly exclaim, "Coleridge is dead!" Even so will some of us speak of Macdonald. He has been so long a familiar figure in the Association that only the older members can think of a day when his name was not yet a household word. Though already well known in his own locality, it was the position he assumed under the new constitution in 1902 which brought him quickly into general notice, so that he was actually the second on the list of Chairmen of the Representative Body. He could be moved to a fiery indignation by injustice, was pitiful for distress or failure; but it was the straightforwardness of the man which gained and held the hearts of all. There were elements in him through which he played some parts in life: strong in body and mind, ready to see an opportunity and steadfast in grasping it, easy to follow because easily understood. These were the things which made him in early life an international football player, and later, for so long, a leader of men. When he rose in a meeting there would be no vague generalities. He spoke to press some definite point or expose a danger, and he would, perhaps, end with a whimsical, almost wistful, smile and "I really do not see what else you can do." Men trusted him, for he trusted himself. Who can say if there was still work for him to do? But we may be glad, as he was glad, that fullness of years was given to him that he might be a pioneer in the constitution of the Association, a strong tower for us while the Insurance Act was in the making, and in other stormy times, and a framer of plans for future good in the quiet days of peace.

Sir EWEN J. MACLEAN writes:

The first vivid impression I have of Macdonald was gained at the Exeter Meeting of the Association in 1907, when he was elected to succeed Victor Horsley as Chairman of the Representative Body. A very different type of man in physique, outlook, and otherwise, but, none the less, a sound instinct had determined the choice. The Association, under its reconstructed machinery and with the compelling personality and ability of Horsley to focus it, had taken much new ground in various directions, and needed a leader of rather the "strong silent" type to bring it, for a time at all events, beside the still waters; and such a man was Macdonald.

Of the strong athletic type of build, his handsome

features, well-shaped head, and silvered hair combined to gather from my meeting over which he presided a quick confidence which was confirmed by the tones of the pleasing, good-carrying voice. His fairness of mind and ready wit were further attributes which went to make him the admirable chairman he was. He would not, however, tolerate for long any fantastic element developing in a debate, or the discussion of any proposal inciting to precipitate action. Many a time in the Representative Body and in the Council would a few sentences from him, charged with kindly satire or strong disapproval, speedily bring the proceedings within the pale of "common sense." When he was not in the chair, to "put up Mac" towards the end of a debate meant to gather and consolidate the practical and feasible points which remained or had emerged in its course.

He had no occasion to seek popularity; it came to him. He was trusted of men, and radiated friendliness. He was a man of intense political conviction, even perhaps of bias, and yet in the days of the insurance negotiations, when feeling was running high, I have seen him, though with some obvious effort, control his words and demeanour better to pursue the task in hand. When acute differences arise, some men display their worst qualities, others their best. To differ from Macdonald did not mean to dislike him. On the contrary, in a captivating degree, he had the capacity of agreeing to differ. As it happens, some weeks ago I met, on a public occasion, the distinguished statesman who was responsible for the Insurance Act, and he said: "How is old Macdonald? He was against us, but I liked him!" Macdonald and I would sometimes, in retrospect, fight over again the feudal battles between our respective clans, and as often as not it would end up by his making the passes of striking a dirk into the bench and jocularly challenging me to remember that wherever a Macdonald sat was the head of the table.

Amongst the many and varied services of outstanding importance which Macdonald has rendered the Association, none, I think, can be counted of greater value than his insistence on sanity of outlook and common sense in its counsels. The many years during which he devoted so much time and energy to arduous work at headquarters and elsewhere must have cost him much in finances and in health, and it is with a full heart I recall that when in Edinburgh last year I said we would welcome him at the Cardiff Meeting, he replied pathetically, "I'll surely come, old man—if I'm alive." We shall miss him profoundly.

Mr. E. B. TURNER writes:

My acquaintance with J. A. Macdonald began more than fifty years ago in the flurry of a scrimmage in a twenty-a-side match played on the Rathmines Ground at Dublin. Both of us being what are now called "front-row forwards," we saw (and felt) a good deal of each other during that strenuous hour and a half. We afterwards cemented our friendship at the dinner, where we sat next to each other. Exactly the same thing happened in the two subsequent years, the first in London, the second in Dublin again. For many years after 1878 (when the last of these meetings took place) I only saw Macdonald occasionally when I met him at an Irish match at Blackheath, Richmond, and later on at Twickenham. I knew nothing of his connexion with or work for the British Medical Association, as I was not then a member. I was therefore astounded, when I attended my first Representative Meeting at the Guildhall, and Dawson Williams took me off to introduce me to the Chairman of Council, to find my old friend and opponent of days gone by in that position. Since then, for the last seventeen years, I have been very closely connected with him in almost every aspect of B.M.A. work—on committees, conferences, and Council meetings. During the war his help to me when I was Chairman of the Representative Body was invaluable, and on those most important committees which followed the peace I more and more learned to value and appreciate his qualities. He never spared himself. He was always ready to give of his very best for the good of the public and of the medical profession. He was a whole-hearted B.M.A. man, and during all the years of his work with and for that body was always ready to do whatever in him might lie to con-

solidate its strength and prestige; and its present high position is in a very great measure due to his long, devoted, and unselfish work. He was a bonny fighter, eloquent and generous in debate, with the God-given gift of humour. An outstanding figure in our profession, we shall not soon look upon his like again.

Sir ROBERT BOLAM writes:

During the last quarter of a century "Macdonald of Taunton" has been a name of moment in the British Medical Association. For more than fifteen years he has been to me a vivid and admirable personality. Admission to the freedom of his friendship these twelve years past has been a high privilege. My first experience on the Council was in the early years of his long term of office as Chairman, before the shadow of ill health fell on him. His effortless grasp of intricate and important business, even at the end of a long tedious day, and his intuitive knowledge of the tendencies of his Council members were always surprising. There was much of personal magnetism in his rule. He could be advisedly silent or speechful himself, would brighten the dull debate with humour, encourage the timid, muzzle the verbose or irrelevant, and quell the insubordinate.

At the annual meetings he was at his best. A tower of strength in difficult situations in the Representative Meeting, by a few sentences he would clarify an apparently hopeless position or prevent some step which would be foolish or unsafe. He was never prone to long speeches at these times. His utterances were pithy and to the point, and on occasion he would thunder with a fine indignation where his feelings were deeply stirred. Then at the various social functions he was equally a prominent figure. Though Ireland was his birthplace, one always thinks of Macdonald as typically British in his demeanour and outlook. He had the best traits of all our island nationalities, even if the humour and the keen political instinct of his home country were two of the most dominant. In his youth no mean athlete, Macdonald was still a golfer when I first knew him, and to the end of his days a sportsman in the highest sense. In medico-politics he was never quite reconciled to the steady inroads made by State and local services on the domain of private practice during the last three decades. Yet he was too much of a statesman to allow his feelings to interfere with his recognition of an inevitable trend. The advance of the British Medical Association in the early years of its present constitution was due in the main to the sound sense and devoted labours of a relatively small band of workers. Among these J. A. Macdonald will always hold a pre-eminent place as a statesman and a worthy ambassador of the profession. In the memory of his friends the picture of that noble head and sturdy figure will ever stand for all that is straight and true and lovable.

Dr. C. O. HAWTHORNE writes:

The announcement of the death of Dr. J. A. Macdonald must bring a sense of loss to all members of the British Medical Association. So prolonged and so conspicuous is his record of service that many who never knew him personally will feel that a commanding figure has gone from amongst us. In the history of the Association his name is written in large and firm characters, and just as he gave gladly, so in turn he received confidence and gratitude in full measure. A prominent memory of Macdonald for those who have been associated with him in counsel, in debate, and in administration will certainly be a recognition of the definiteness of his views and opinions. To differ from him was, of course, possible, but not to misunderstand him. Never hurried in his conclusions, and not unduly impatient of opposing arguments, he had a large capacity for decision and an ability to stand fast where he had chosen his ground. These qualities made him an ideal chairman and an efficient administrator. In similar fashion he was a really gallant ally, and equally a formidable opponent, when a fighting campaign was in progress; and he had a manifest joy in battle that engaged the goodwill even of his friends the enemy. His mind, like his physique, was of the robust order, and though circumstances sometimes compelled him to compromise he had no love for this ~~sort~~ of strategy;

what appealed to him was the rigour of the game. Yet, withal, he was a very lovable personality, and in the inner counsels of the Association it is not only his wisdom and commonsense and experience we shall miss, but also his generous and large-hearted fellowship.

Dr. H. B. BRACKENBURY writes:

It was not until after my election to the Council of the Association in 1914 that I knew Macdonald, though I think I had previously attended at least one conference of which he also was a member. He was at that time Chairman of Council and of the Insurance Acts Committee, and he acted also as chairman of the Conference of Local Medical and Panel Committees. My first impressions were of a striking and attractive personality and an extraordinarily capable and effective chairman. Later one discovered, along with one or two ingrained prejudices which often influenced his pronouncements rather than his actions, a soundness of judgement, a grasp of hard facts, and an appreciation of practical difficulties which made him a wise counsellor and a valuable leader of opinion. It was perhaps a little difficult to become intimate with him, but a natural and innate reserve did not succeed in obscuring a broad and abundant sympathy. His was a powerful intellect and a strong character, and he placed these and all his great abilities at the disposal of the Association and profession to a degree and with an unselfishness which have, I think, never received sufficient appreciation and acknowledgement. Over a long series of years he sacrificed time, energy, economic prospects, in the interests of his fellow practitioners and of the organized profession. In these interests he worked hard and continuously and wisely, especially in connexion with the British Medical Association and the General Medical Council, to the amazement of those who were in a position to appreciate what he was doing, and in a way which deserves the great gratitude of all those who have benefited thereby. The memory of his fine figure, lovable personality, and trusted leadership is one to cherish.

Mr. N. BISHOP HARMAN writes:

To Macdonald there fell the unique lot of guiding the counsels of our Association, and through them the profession at large, during some of the most stirring epochs of the last hundred years of medical life. There never was a time when medical opinion and temper were so stirred as during the passage of the Insurance Bill through Parliament. There never was a time when national life was so stirred as during the great war. Through the years of formation of professional opinion before the launching of the original Insurance Bill, and during the negotiations of the terms of the bill, Macdonald was at the helm. Again, in that other epoch, perhaps more cataclysmal than any other of the world's history, in the time of the war, Macdonald was at the helm of the Association's affairs. He was Chairman of Council from 1911 to 1920, and through all these years he devoted himself to the service of his professional colleagues and their business in a manner that few have realized. The character of his work that strikes the mind, when one attempts to judge its quality and to sum up the impressions of it in some terse expression, was balance. He was a man in whom there was shown to the full that perfect coherence of cool thought and calm judgement that gave a perfect poise in the times of human storm, when passions were aroused and temperaments were battling in the dust of the arena. During these difficult years, when sides waxed and waned, he never lost his sense of proportion or failed to keep a fair balance between the swaying parties he had to guide. Reputations were made and marred, but his steadily appreciated. Surely that was the mark of a man of worth. It is sometimes suggested that physique and character are correlated, that the one is the reflex of the other; it surely was so with Macdonald. In physique he was stability personified, though not of the sort shown by the stone pylon, which is stable by virtue of its weight, for with all his solid strength he possessed a manifestly strong current of vitality, which was part of his stability. If there be an "inferiority complex" that forces some to vindicate their existence, to assert that they are there, then Macdonald was born with a most enviable "superiority complex" that gave him a mind

above pettiness, above demagoguery, and filled him full of a golden common sense that saw things both near and far in a comprehensive view. It was a great thing for our profession that there was a man of his calibre at the helm in those days. In these last years, when age and infirmity gave him less time and vigour to work for the Association, he yet found time to serve as the chairman of the Journal Committee, and it is sad to think that within so short a time both the Editor, with whose life-work Macdonald was so closely woven, and the chairman of the Committee that supervises the work of the *Journal* should have reaped their last laurels and passed to their rest.

Two incidents of the stormy years of the Insurance Bill recall to my mind his mastery of affairs—the occasion when the Special Representative Meeting, held at the old Examination Hall of the Conjoint Board on the Thames Embankment, when he guided the proceedings on the visit of the Minister in charge of the bill, and again, a little later, when I met him one Sunday morning after the fateful Council meeting, when he told me of the decision of the Council with regard to the transfer of the services of one of the officials of the Association to the service of the Government. He saw clear-eyed the storm that these actions forecasted, but he did not for one moment quail or hesitate in guiding his colleagues along a path that events and calmer days have justified. Macdonald was an ideal chief, for he was a good comrade. He was massive and yet genial, fearless but kindly. He will live in the memory of the generation that succeeds him as an inspiration.

Sir JAMES BARR writes from Jersey:

It is with extreme regret that I have learned of the death of Dr. J. A. Macdonald. It is only a few weeks since he paid a warm tribute to the memory of Sir Dawson Williams, and now his numerous friends have to deplore his own death. He has long been well and widely known as an outstanding figurehead of the British Medical Association, but comparatively few knew how much the medical profession, and especially the Association, owe to his untiring and unselfish energy. The amount of work and time which he devoted to his public duties was given ungrudgingly and without any personal ends in view. Macdonald's ambition was the aggrandisement and welfare of the medical profession.

He was never a keen controversialist, but he was an ideal chairman, and although he allowed contending forces fair liberty in debate, he never tolerated any licence. He was always firm in his decisions, which were invariably respected by all parties. I was closely associated with him during the stormy times preceding the Insurance Act, when the vast majority of the medical profession were in opposition to the bill; but when the Act became a *fait accompli*, although a stubborn North of Ireland man, he was able to adapt himself to the working of the Act, and piloted the Association through troubled waters into a safe harbour. With his wish I had the pleasure and honour of acting as his deputy in the Council chair during his visit to the antipodes in 1914. Honours and dignities have been showered on less worthy men, but his ambition was not personal, but professional. The Council of the Association recognized his supreme merits, and conferred on him all the honours that were in its power to bestow. He had the personal misfortune to remain a bachelor, but he was wedded to his profession, and had he become a Benedictine the medical profession would have been the losers.

Macdonald was a prominent member of a band of distinguished graduates of the Queen's University who settled in this country in the seventies. Perhaps his first introduction to England was as an international Rugby footballer. I well recollect in 1912, when I was introducing Dr. Gordon of Maghull to him, that they had both played together against England. They were then most loyal subjects, and prepared to fight for England; but when the British Government in their Home Rule escapades were prepared to betray and coerce Ulster, the most loyal part of the Empire, Macdonald was among the first to join Carson's Covenanters. All the Queen's University men to whom I have referred have held prominent public and

professional positions in this country, have been an honour to the country of their birth as well as to that of their adoption. A good many of them are now dead, and the latest to join the great majority, Dr. Macdonald, will be long and affectionately remembered by all who knew him. I feel that I have lost another dear personal friend, and I much regret that I am not now in a position to attend his obsequies.

Dr. MILNEN MOORE (Eastbourne) writes:

I should like to add my tribute of respect and admiration for the late J. A. Macdonald. For many years I have watched his devotion to the interests of the British Medical Association and its members, having sat at his feet when he was Chairman of the Representative Meetings, in the conduct of which he was ever firm, courteous, and discerning. I have admired his manly figure, his captivating brogue, and his ready response to any question asked or suggestion proposed. I regret indeed his loss to the Association and to all those who may have been nearest and dearest to him.

Dr. ALFRED COX writes:

I first met Macdonald at the historic conference called by the Medical Guild in May, 1900. The conference consisted of representatives of local medical societies, of a few Branches of the British Medical Association, and of the Council of the Association, and its influence on the future of the Association was immense, as all those who have read Dr. McVail's account (which was published in the *British Medical Journal* of June 7th, 14th, 21st, and 28th, 1924) know well. Macdonald came as a representative of the West Somerset Branch of the Association; he took little part in the debates, but impressed all of us with his personality. He said afterwards that he had very little knowledge of the subjects to be discussed, and had gone more or less out of curiosity, but his visit was the means of leading him into the life of the Association, and it was not long before he became an acknowledged leader. The seal was put upon his position when he was elected to follow Horsley as the second Chairman of the Representative Body. Horsley was a most masterful person, and there were many who were doubtful whether anybody could successfully follow him in an admittedly difficult position. But Macdonald quickly allayed all fears, and he loved to be reminded of the fact that within half an hour of taking the chair he had called Sir Victor Horsley to order, an event which caused great joy to all who witnessed it. From that day onwards Macdonald became and remained a leader in the Association—trusted, admired, and liked as few men have been. It has always been a subject of wonder to me how he, a single-handed general practitioner, could give up the time he did to the Association and the profession generally. I suppose that, averaged over the last twenty-five years, a day a week would probably be an under-estimate. He explained it by saying that a man must have a hobby and be prepared to pay for it, and that he had the best of neighbours and colleagues. Macdonald was one of those fortunate men who are born with a strong personality. One could not be in the same company with him for long without being impressed by it. He had very strong prejudices, and never concealed them, but he was the soul of honour, and I could not imagine him ever doing a shady action. The Association owes to Macdonald far more than it could ever repay, and the place he made for himself in the profession, by sheer force of personal character, was unique.

Mr. W. E. HEMPSON writes:

I should wish to say a word in tribute to the memory of J. A. Macdonald. Friendship between us dated from our first meeting some twenty-five years ago, and became more closely cemented year by year. He was in truth a boon companion, a staunch friend, and a generous foe—with a "white man," a sportsman, and a gentleman. How few one meets in life who can claim these attributes to the full measure that he enjoyed them, borne with a modesty which disarmed criticism or envy. Had the Representative Body been canvassed in point of individual popularity, Macdonald would without doubt have headed the

list. In debate his voice was never heard on any subject without good occasion arising, and when he spoke he struck home and carried conviction. His honesty of purpose in everything he said and did was universally accepted. Such is my experience of our old friend, and the affection which I bore towards him will remain green in my memory.

The death is announced of Dr. JANE HENDERSON RUTHVEN, one of the best known medical women in Johannesburg, which took place in the General Hospital there on March 28th, after a brief illness. Dr. Henderson, as she then was, received her medical education at the London School of Medicine for Women, and studied later in Paris. In 1890 she obtained the Scottish triple qualification, L.R.C.P., L.R.C.S.Ed., and L.R.F.P.S.Glas., graduating M.D.Brux. in the following year. She had the distinction later of being one of the first medical women to be appointed to the resident staff of a mental hospital, and for two years was assistant medical officer at the Holloway Sanatorium, Virginia Water. Subsequently she commenced practice in Glasgow, where she remained for about seven years, during which time she devoted herself largely to work at the Wynd Mission Dispensary in that city. In 1902 her association with South Africa began, when in the aftermath of the war she received an appointment under the Colonial Office for work in connexion with the concentration camps, and became medical officer of the camp at Krugersdorp. On her marriage soon afterwards she took up her residence in the country, but for many years past had been living in Johannesburg, where in addition to carrying on private practice she was one of the medical officers at the school clinic. Dr. Ruthven's activities, however, extended considerably beyond the affairs of her profession; she took a leading part in various women's movements, and for a number of years was president of the Women's Enfranchisement League. She was also a vice-president of the Women's Civic Society and a member of the National Council of Women; she was, in 1909, elected a Fellow of the Royal Society of Arts, and had recently contributed to the proceedings of the South African Society for the Advancement of Science a paper on international intellectual co-operation. Social and political affairs generally possessed a deep interest for her, and she had travelled extensively in Europe and America. Among other activities may be mentioned her work in connexion with the District Nursing Association, her membership of the League of Nations Union, and her interest in the affairs of the St. George's Presbyterian Church, Johannesburg, in which she was recently elected a manager.

Dr. JOHN LAWSON RANKINE, who died suddenly on April 14th, was born in 1881, and received his medical education at Oxford University and Guy's Hospital, London, obtaining the diplomas M.R.C.S.Eng. and L.R.C.P.Lond. in 1907. He then served for a period as house-surgeon at the Dumfries and Galloway Royal Infirmary, and later was a clinical assistant at the Royal Eye Hospital, Southwark, before embarking in practice in the Border district, first at Mallsburn, Bewcastle, and at Fergus Hill, Kirkcubright, and finally at Longtown, where he spent the greater part of his professional life. He was medical officer of health for the Longtown rural district, and took a considerable part in organizing the provision in the area for dealing with infectious disease. During the war he was for a time in charge of the local Red Cross Hospital, and later received a commission in the Royal Army Medical Corps, serving in the East with the acting rank of major. References to his death were made in the churches of several denominations, and a memorial service, held in Arthuret Parish Church, Longtown, was largely attended by all classes of the community, and notably by representatives of the public health service and the medical profession. Dr. D. C. Edington and Dr. G. T. Willan represented the British Medical Association, of which Dr. Rankine was a member. He is survived by his widow, a son, and a daughter.

Dr. FRANCIS PENNY, who died in Doncaster Infirmary on April 15th from injuries received in a motor accident five days previously, was until recently medical superintendent at the Barnsley and Wakefield Joint Sanatorium, Mount Vernon, Barnsley. He received his medical education at King's College, London, where he was a Warneford Scholar, and in 1884 obtained the diplomas M.R.C.S.Eng. and L.S.A.Lond. As a house-surgeon at King's College Hospital he was associated with Lord Lister. Subsequently he held resident posts at the North Devon Infirmary, Barnstaple, and at the Doncaster Infirmary, and served as a civil surgeon in the South African war. A keen interest in travel and exploration later led him to seek employment abroad, and he acted at various times as medical officer to various mining companies in regions so diverse as Spitzbergen and Central Africa. During the late war he served at sea, and in more recent years was, for a period of about six years, medical superintendent at the Mount Vernon Sanatorium. At the time of his death he was engaged in preparations for a voyage to New Zealand. A former colleague writes: Francis Penny was much loved, and was very popular with his patients. He held very decided opinions in various medical matters, and strongly believed that most of our modern ailments were due to overeating. He believed in periods of fasting, and never, of late years, took more than two meals a day. He rarely used tuberculin in his practice, and avoided the use of all serums and vaccines as far as possible. Penny was one of the pioneers in the use of ultra-violet light, and his results in the treatment of lupus were very satisfactory. He was a good tennis player, and often defeated opponents more than twenty years his junior, and he was also very fond of dancing. The funeral service was held at Lawnswood Crematorium, Leeds, and was attended by several members of his family, including his brother, Colonel Penny, A.M.S. (retired), the mayor of Barnsley; the chairman of the Health Committee of Wakefield; and the medical officers of health for Barnsley and Wakefield.

The late Dr. GEORGE CHARLES KAROP, who died suddenly at his residence at Herne Bay last August, was of Danish descent but of English birth, having been born in London in 1853. He was educated in part at Heidelberg, and afterwards entered as a medical student at the Middlesex Hospital, obtaining the diplomas M.R.C.S.Eng. and L.S.A. in 1875. For about a year he held a resident post at this hospital, subsequently becoming a surgeon in the service of the Royal Mail Steam Packet Company. He next returned to the Middlesex Hospital as tutor in physiology in the medical school, with notable success as a teacher, and later was for ten years clinical assistant at the Royal London Ophthalmic Hospital (Moorfields). In London, and later at Herne Bay, to which place he removed in 1907, he built up a considerable practice as an eye specialist, being for many years honorary ophthalmic surgeon to the Herne Bay Queen Victoria Memorial Cottage Hospital. Throughout practically the whole of his life Dr. Karop took a keen interest in microscopy, being closely identified with the Quekett Microscopical Club, which he joined in 1873, and of which he was the honorary secretary from 1883 to 1904. He was also a Fellow of the Royal Microscopical Society, and served for a time on the council of that body. Microscopical research was his chief hobby, his main interest, apart from its medical aspects, being in the *diatomaceae*. He took no prominent part in public affairs in Herne Bay, but he was a well-known and respected figure in that town, where he was much esteemed for his personal qualities. His wife died in 1926; he is survived by three sons and a daughter.

The following well-known foreign medical men have recently died: Dr. JEAN DANYSZ, of the Institut Pasteur, Paris, Commander of the Polish Order Restituta, aged 67; Dr. EUGENE HERTOGE, vice-president of the Royal Academy of Medicine of Belgium; Dr. L. KLEINWÄCHTER, formerly professor of obstetrics at Czernowitz, aged 89; Dr. OSKAR BAIL, professor of hygiene at the German University of Prague; and Dr. RICHARD PRIBRAM, professor of physical chemistry at Vienna.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on May 8th there will be two clinical demonstrations, one at 2 p.m., at the Cancer Hospital, by Mr. Ernest Miles, and another at 2.30, by Dr. Frew, at the Hospital for Sick Children. On May 9th Mr. Greaves will give a demonstration at the Royal London Ophthalmic Hospital; all three demonstrations are open to members of the medical profession without fee. Several courses are being given throughout May. In addition to those already in progress, on May 7th four other courses begin. These are an afternoon course for two weeks at the Infants Hospital; a course in diseases of the throat, nose, and ear, occupying all day, for three weeks; an afternoon course in ophthalmology, continuing for four weeks; and a course in neurology at the National Hospital, Queen Square, which continues to June 29th. Full particulars of all special courses and of the general course of work may be obtained from the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE third lecture of the post-graduate course on cancer, at the Leeds Medical School, under the joint auspices of the Leeds and West Riding Medical-Chirurgical Society and the Yorkshire Council of the British Empire Cancer Campaign, will be given on May 9th, at 3.30 p.m., by Professor G. Grey Turner, his subject being cancer of the rectum. The lecture is free to medical practitioners, who should, however, inform the secretary of the British Empire Cancer Campaign, 47, Park Square, Leeds, of their intended presence at least two days previously.

THE spring meeting of the South Wales Medical Golf Society will be held at Southerndown golf course on Thursday, May 17th. The divisional stage for the Treasurer's Cup (for the Cardiff Division) will also take place on the same day at Southerndown. Other Divisions of the British Medical Association wishing to hold their competitions on the same date are asked to communicate with Dr. T. Garfield Evans, 127, Cathedral Road, Cardiff.

A CONFERENCE to consider the position of women in the service of hospitals will be held at the Mary Sumner House, 24, Tufston Street, Westminster, from 2.30 to 6 p.m. on Tuesday, May 8th. The speakers will include Dr. Graham Little, M.P., Dr. Margaret Emslie, Miss Eleanor Rathbone, and Miss C. Fulford, and the three questions to be discussed are: (1) opportunities for training of women medical students; (2) the appointment of women to paid and honorary medical posts in hospitals; and (3) the appointment of women on boards or committees of management of hospitals (including mental hospitals). Visitors' tickets (price 1s.) and further particulars may be obtained from the National Union of Societies for Equal Citizenship (which has convened the conference), 15, Dean's Yard, S.W.1.

ON his departure to take up the appointment of medical officer of health for East Sussex Dr. R. Asbleigh Glegg, who has been M.O.H. to the Lindsey County Council for the past twenty years, was presented with handsome gifts from his associates—doctors, dentists, nurses, and clerks—of the health department and from the staff of the county council as a whole.

A RECENT change in the by-laws of the Royal Society of Medicine extends the privilege of associate membership to dental and veterinary practitioners on the terms formerly applicable only to members of the medical profession. The associateship is therefore open, subject to election by the Council, to members of the three professions who apply for election within five years of their first professional qualification, at the end of which period the privilege lapses. An associate who has paid three annual subscriptions may, if elected to the Fellowship, be admitted without payment of entrance fee.

THE West African Medical Staff List, revised to show the appointments held by officers on November 30th, 1927, gives a total of nineteen specialist and research appointments, one in Sierra Leone, eleven at the Research Institute for the Gold Coast, and seven at the Lagos Research Institute. The total establishment of the staff is now 215.

PENDING international agreement about bacteriological nomenclature the *Bulletin of Hygiene* has provisionally adopted a system based on that recommended by the 1920 report of the committee appointed by the American Society of Bacteriologists. A description of this system is published in the February issue of the *Bulletin*.

AS in several recent years, the Italian State Tourist Department is organizing a special study tour for medical practitioners to the spas and health resorts of Italy from September 5th to 21st. The tour is restricted to foreign practitioners to the number of 150, and will be conducted by a special first-class train throughout. Assembling at Milan, the party will visit a number of centres of medical interest in Lombardy and Piedmont, including the Italian lakes and the Italian Riviera, before dispersing at Viareggio. At each

spa a medical lecture will be given, followed by visits to bathing establishments, etc. The texts of lectures will be provided in English, French, and German, and interpreters familiar with these languages will accompany the party. The inclusive charge will be 1,500 lire (about £16 10s.) for the tour; reduced fares will be available in Italy to and from the points of assembly and dispersal. Full information may be obtained from the Ente Nazionale Industrie Turistiche (Italian State Tourist Department), Via Marghera 6, Rome.

THE ninth international neurological congress will be held in Paris on July 3rd and 4th, when a discussion will be held on the diagnosis and treatment of cerebral tumours, in which Drs. Clovis, Vincent, Bédère, Bollack, Hartmann, and de Martel will take part.

A MEDICAL congress on diseases of the respiratory tract will be held at Clermont-Ferrand, under the presidency of Professor Castaigne of Paris, and will include excursions to La Bourboule and Mont Dore on May 27th and 28th. The subjects for discussion will be the treatment of tuberculosis in the spas of Auvergne and centre of France, treatment of diseases of the pharynx and larynx at these spas, and injection of mineral waters into the tissues. Further information can be obtained from the Centre Médical, 23, Place Bréchin-haut, Moulins (Allier).

THE fifth international congress of thalassotherapy will be held at Bucarest and Constantza from May 21st to 29th. Further information can be obtained from the general secretary, Strada Mantuleasa 35, Bucarest.

DR. AUGUST GÄRTNER, professor of hygiene at Jena University, celebrated his eightieth birthday on April 18th.

ACCORDING to the Stockholm correspondent of the *Times* this year's Nobel Prize winners will receive about £8,700 each from the Nobel Foundation. The prizes to be awarded in 1928 are for physics, chemistry, medicine, and literature.

A PRIZE of 3,858 francs will be awarded by the Société de Neurologie of Paris for the best work on the treatment of disseminated sclerosis published between July 1st, 1927, and July 1st, 1928. Further information can be obtained from Dr. O. Crozon, 70 bis, Avenue de Jéna, Paris.

A BILL has been introduced in the Legislature of Trinidad and Tobago to provide for the medical inspection of Government and assisted schools and of the pupils attending such schools.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9561, 9563, 9564, and 9565 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, *Antiology Westcent, London*.

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), *Articulate Westcent, London*.

MEDICAL SECRETARY, *Medisecra Westcent, London*.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 6, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

## QUERIES AND ANSWERS.

### HARDENING THE FEET.

"H. R." wishes to know the best method of hardening the feet preparatory to a long walking tour.

### INCOME TAX.

#### Cash Basis.

"J. C. G. C." started practice in 1926-27 and paid tax for that year on the basis of his gross bookings less expenses. Can he now adopt the cash basis?

The revenue authorities object to the cash basis as applied to a new practice until the point is reached at which the receipts from old bookings are likely to balance the unpaid

accounts for the year for which the account is paid. Probably they will insist on the "bookings" basis for at least three years. It should be borne in mind that it is the probable value of the outstanding debts which should be brought in, and therefore if there are any particular cases in which it is not expected that the whole amount will be received, deduction should be made for probable specific losses.

#### Deduction for Use of House.

"S. H." owns his house, which is assessed at a net value of £45. He has claimed to deduct, as representing the professional portion, the sum of £25 "as one-third of a reasonable rental value." The inspector of taxes declines to allow more than £15—that is, one-third of the net assessed value.

The assessed value must be taken as the basis, and therefore the inspector's attitude is correct. "S. H." should, however, bear in mind that as £45 is the net value, any cost of maintenance, repairs, etc., applicable to the professional portion of the house may be separately charged as professional expenses.

#### Motor Car Expenses.

"N. B. C." inquires which of the expenses incurred in running a car for professional purposes may be deducted from gross income.

All expenses may be deducted except those incurred in the purchase—as distinct from the cost of replacement—of the car or its improvement. This includes, for instance, the annual cost of insurance, but, of course, the sums received must be brought in against any expenditure resulting from accident, etc. To the extent, however, to which the car is used for private purposes the total cost must be restricted—for example, by 10 per cent., or whatever percentage may be reasonable.

#### Motor Car Transactions.

"I. L." bought a Singer car for £145 in February of this year. What allowance can he claim for 1928-29?

Depreciation, namely, 15 per cent. of £145—that is, £22. When the car is replaced an obsolescence claim can probably be made, as 15 per cent. is usually found insufficient in such circumstances.

"E. W." bought a car in 1926 for £170. He has now sold it for £60 and bought another car for £170. No depreciation has been claimed.

The actual out-of-pocket cost of the new car—that is, £170-£60=£110—can be claimed as a professional expense of the current year. It will be seen that it is the income-tax return for 1929-30 and not for the current financial year that will be affected.

"A. P." inquires what is the annual percentage figure for depreciation on a car for the first, second, and third years.

The normal rate granted appears to be 15 per cent., though no doubt there are cases where 20 per cent. is given, having regard to the nature of the work the car has to perform. The rate is applied to the "written down" value—that is, the cost price as reduced by allowances for the previous years. On a car costing £400 the allowances would work out as follows:

First year—£400 at 15 per cent.=£60, leaving £340;  
Second year—£340 at 15 per cent.=£51, leaving £289;  
Third year—£289 at 15 per cent.=£43, leaving £246;

and so on.

#### LETTERS, NOTES, ETC.

##### PROGNOSTIC SIGNIFICANCE OF LARGE NUMBERS OF TUBERCLE BACILLI IN PUS.

DR. B. R. CLARKE (Bellast), referring to Dr. Cobbett's article on the relative frequency of human and bovine tuberculosis in our issue of April 14th (p. 626), reports the case of a woman, aged 20, who, following pleurisy at the age of 10, was admitted to hospital with physical signs of infiltration of the upper half of the right lung and the upper fourth of the left lung. The sputum was examined four times for tubercle bacilli without result. The patient improved rapidly, the temperature becoming normal after nine weeks in hospital. Nearly a year later a rapidly caseating tuberculous gland developed on the left side of the neck, and the patient began to lose ground steadily. Meningitis supervened and the patient died. Pus aspirated from the swelling was found to contain tubercle bacilli in large numbers; in appearance they were long and thin, and contained no granules. Lesions of the human type appeared in an inoculated guinea-pig.

##### BODY AND MIND.

MR. F. MATTHIAS ALEXANDER (London, S.W.) writes: Dr. A. Murdoch of Bexhill-on-Sea has drawn my attention to your leading article entitled "The reality of delusions" in the *British Medical Journal* of March 17th (p. 437). Dr. Devine's conclusion, which you quote, that a delusion is "the conscious symbol of a morbid state of functioning of the whole organism," and his preceding statement that both physical and mental illness are "the expression of disturbances of the organism," are of more

than ordinary interest to me, as my practical teaching experience of over thirty years has been based upon the impossibility of separating the so-called mental and physical elements in any of our dealings with the human organism. The "disturbances of the organism," which Dr. Devine states express themselves in "both types of malady," I have found to be due in every case to wrong use and malfunctioning of the whole organism. I have evolved a technique the object of which is to restore to my pupils a right use of their whole organism and not to treat manifestations of disease in which I am not interested. I have found that where its application is successful, symptoms, whether manifesting themselves as "physical or mental illnesses," tend alike to disappear in process; and medical men who have sent pupils to me, and whose names I enclose, can verify this. Dr. Peter Macdonald brought out this point very clearly in the address which he gave to the Yorkshire Branch of the British Medical Association, and which you published on December 25th, 1926; and in my book *Constructive Conscious Control of the Individual*, to which you gave a favourable review, I made my position quite clear at the outset by defining my use of the term "psycho-physical" as covering all manifestations of human activity. When you express the hope that the gap between psychological medicine and medicine at large may narrow rather than widen, may I suggest that the first step towards such an integration must be a statement of a technique by means of which the cause of the "morbid state of functioning of the whole organism," which Dr. Devine states lies behind mental and physical illnesses alike, may be found and eradicated?

##### STREPTOCOCCI AND PURPURAL SEPSIS.

MR. J. T. AINSLIE WALKER (London) writes: If Professor Beattie's reference to the Rident-Walker test in his letter in your issue of April 14th was intended to imply that the only organism used in this test is *S. typhosus*, he has given an entirely erroneous impression. In my original note, published in the *Practitioner* in 1932, I gave an example from my laboratory note-book, showing the result obtained for a certain preparation X when working with *B. coli* as the test organism. The multiple, or coefficient, was 10.0. The following quotation is taken from the same note: "Of course, a different multiple will be found when working with different organisms. In the case cited above the multiple found for X when tested against a pure culture of *S. pallida aureus* was 4; but this only bears out Dr. Houston's excellent observation on the necessity for the choice of a disinfectant being governed by the purpose to which it is proposed to put it."

##### THE "RISING TEST" FOR ACUTE ABDOMEN.

DR. K. RAPP (Biberach, Württemberg), referring to Mr. C. L. Granville Chapman's memorandum on a diagnostic test for acute abdominal conditions (October 29th, 1927, p. 788), states that he first recognized the value of this test in appendicitis in 1921, and published a note on it in the *Medizinische Klinik* (1925, No. 41), giving it the name of *Rumpfbereugungsschmerz*. He agrees with Mr. Chapman as to the assistance given by it in the stage before abdominal tenderness appears.

##### CHRONIC DIARRHOEA CAUSED BY A FEATHER QUILL.

DR. H. E. JONES (Glasgow) reports the case of a man who had suffered for many years from pain in the bowels and diarrhoea: he was considerably relieved, but not cured, by treatment with pilul. kino co. He subsequently passed through the bowel a hard, brittle, smooth, polished and somewhat flattened tubular fragment, which was brownish and about the size of an ordinary match. It had been removed from the bowel with considerable difficulty, and subsequently the patient had no diarrhoea, and the abdominal pain and discomfort entirely disappeared. The specimen appeared to be a quill from the wing or feather of a small brown bird. The patient stated that when in South Africa several years previously he frequently dined on snipe and guinea fowl, and might quite easily have swallowed a quill. Commenting on this case Dr. Jones writes: I have been considering very carefully the question of diagnosis and the line of treatment I should have adopted had I previously known that such a foreign body was in the bowel. In the first place, to diagnose a foreign body such as a quill is by no means easy. A quill stuck into a sausage and x-rayed only throws a faint shadow, which would be almost imperceptible were the sausage placed within the abdominal wall. To find a solvent that will dissolve a quill is a difficult matter. Hydrocyanic acid—such as hydrochloric and sulphuric—and soda—and potassium iodide or bromide, a feather or quill. Bromine converts a feather into a brown mass, and nitric acid causes a feather and quill to disappear completely, but neither of these could be used for medicinal purposes. Since wild animals, such as the fox, eat birds, including their feathers, their digestive secretions must contain some solvent which acts upon feathers and quills, or else they must pass through the alimentary canal undissolved. I should be glad to have the opinions of others on this point.

##### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 54, 55, 56, 57, 60, 61, and 62 of our advertisement columns, and advertisements as to partnerships, assistantships and locum tenencies at pages 53 and 59. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 203.

## An Address ON THE PATHOGENESIS OF ACUTE PRIMARY GLAUCOMA.\*

BY

A. MAITLAND RAMSAY, M.D., LL.D., F.R.F.P.S.,  
HONORARY DIRECTOR, JAMES MACKENZIE INSTITUTE FOR CLINICAL  
RESEARCH, ST. ANDREWS; CONSULTING OPHTHALMIC SURGEON,  
GLASGOW ROYAL INFIRMARY AND OPHTHALMIC INSTITUTION.

GLAUCOMA is not a disease in itself, but rather a symptom-complex whose characteristic feature is increase in the tension of the eyeball. It was, however, the peculiar greenish reflex from the pupil that first attracted attention and suggested the name glaucoma. Centuries had to pass before William Mackenzie drew attention to the hardness of glaucomatous eyes. That was the first observation of real value in the study of glaucoma, and may be regarded as the foundation of all present-day knowledge of the subject.

When considered from the clinical standpoint glaucoma may be primary or secondary; primary when it is unassociated with any other disease in the affected eye, and secondary when the glaucomatous seizure arises as a complication of a pre-existing pathological condition. The attack is acute or chronic, according to the presence or the absence of congestion of the ocular blood vessels, but inflammation in the strict sense of the word never occurs during the course of acute primary glaucoma. Venous congestion is alone responsible for the severity of the symptoms, which vary greatly in degree in different cases. In the majority they are subacute and recurrent, but in a small proportion they may be described as fulminating. In these circumstances glaucoma is seen in its most tragic form—the onset, course, and termination being the incidents of a few hours. A single attack occurring with dramatic suddenness results in total and irrevocable loss of sight. Such a disaster is all the more overwhelming, because glaucoma usually affects both eyes, and although one may be attacked considerably in advance of the other, yet in a few desperate cases both suffer simultaneously.

### SYMPTOMATOLOGY.

Acute glaucoma can be described as one of the emergencies of general practice, and in many instances it appears to come as a bolt from the blue. The patient goes to bed apparently in his usual health, but in the early hours of the morning is awakened by agonizing pain in the head, accompanied by feverishness, nausea, persistent retching, and bilious vomiting. The condition is so alarming that the family doctor is sent for in haste, and unless he knows well what he is about he may easily do the patient more harm than good. It is quite probable that no one will speak about the eye, because even although the failure in vision has been noticed, it has been tacitly assumed to be due to biliousness. The attention of the patient and of those surrounding him is occupied wholly as a rule with the severity of the pain in the head, the nausea, and the vomiting. The true nature of the condition, therefore, may be easily overlooked, and if the doctor is also deceived the result will be deplorable.

Acute glaucoma is not by any means a common disease. It may happen that a medical man has been many years in practice before he is called to treat a case. He ought, however, always to bear the disease in mind, and never to forget to examine the eye of a patient said to be suffering from a severe bilious attack. Every country doctor ought to be able to recognize acute glaucoma. There is not much difficulty in the diagnosis. The eye is tender and the patient shrinks from the slightest touch; it is hard, and said to feel too big for its socket. The bulbar conjunctiva

is congested and oedematous; the cornea is steamy and in many instances so insensitive that it can be touched without the patient's knowledge; the pupil is dilated, irregularly oval shaped, and irresponsive to light; the anterior chamber is shallow. At this stage of the examination the general practitioner must be on his guard not to misinterpret the significance of these signs and symptoms.

The chief local condition with which acute glaucoma is often confused is acute iritis; but the stony hardness of the eyeball, the dilated pupil, the shallow anterior chamber, and the loss of sight form a group of signs sufficiently diagnostic to prevent glaucoma from being mistaken for any other disease. Unfortunately, however, glaucoma and iritis are still confused by the unwary, and the consequences of such an error in diagnosis are deplorable, because the treatment for glaucoma is the opposite of that for iritis. It is well known that in iritis the vigorous use of atropine is imperative, but it is not so well known that if a mydriatic be instilled into an eye suffering from glaucoma the symptoms will be aggravated and the chances of recovery of sight will be materially lessened. There are few errors in diagnosis which are followed by such disastrous results.

Although the patient may never have consulted a doctor regarding his eyes until the onset of the acute symptoms, careful inquiry into the history of the case will usually elicit the fact that for weeks, months, or years he has suffered from transient attacks of dimness of vision. These attacks are often so fleeting that little significance is attached to them, and as a rule the patient does not think it worth while to mention them until something in the course of a medical examination recalls them to mind. The fact that such attacks are usually made light of and quickly forgotten makes it all the more necessary for the family doctor to be quick to appreciate and appraise at their proper value any remarks regarding eyesight made in a casual manner during the course of conversation.

Suspicion should at once be aroused if a patient says that now and again he has seen objects through a fog, and that lights have appeared to be surrounded by rainbow-coloured rings. Inquiry will usually further elicit that while these symptoms are present there is a dull pain in the eye and forehead, and if it should happen that the doctor was consulted during one of these attacks he will remember that the eye was more or less red, hard to the touch, the cornea steamy, and the pupil dilated. If the examination be carried further by the use of the ophthalmoscope it will be seen that the retinal veins are enlarged and that the arteries pulsate as they pass over the optic disc. When the patient is kept under regular observation it will be discovered that the attacks are recurrent and vary in duration from a few minutes to several hours, while in the intervals the eye to all appearance is healthy. Recurrences become more and more frequent and protracted, however, until at length a state of increased tension is permanently established. In the majority of instances that sequence of phenomena is easily followed, but there is usually considerable difficulty in understanding the underlying cause of the condition.

The increased tension of the eyeball is not a disease in itself; it is only a symptom of a general condition, whose etiology is at all times very difficult to determine. When an eye is predisposed to glaucoma anything that depresses the action of the heart may determine a seizure, which in the majority of instances can be clearly traced to mental distress or moral shock, to the injurious influence of cold or of hunger, or to worry, sleeplessness, or fatigue. In many instances also there are present such associated conditions as anaemia, lithiasis, bronchitis, persistent constipation, or the suppression of some habitual discharge. Acute glaucoma occurs frequently in women at the menopause. Lagrange has defined glaucoma to be "a sick eye in a sick body," and Laquer says that everything "that dilates the pupil or debilitates the patient" may precipitate an attack. It is characteristic of the onset of the disease that the increase of tension is intermittent, but sooner or later it becomes permanent. By the time that stage is reached, however, the cause of the disease is usually obscured by its results.

\* Delivered at the James Mackenzie Institute for Clinical Research, St. Andrews, on March 20th.

## ETIOLOGY.

The earlier glaucoma can be detected, therefore, the more likely is its etiology to be discovered. No progress will be made with this quest, however, until the physiological mechanism whereby the intraocular tension is maintained in a state of health is properly understood, because without such knowledge it is not possible to detect the earliest aberration which transforms the physiological into the pathological. It must be borne in mind that there is no essential difference between physiology and pathology. No sharp line of demarcation separates the normal from the abnormal. By the recognition of symptoms, however, the trained clinician is able to detect the beginnings of disease, at a time when the morbid process giving rise to it is still on the borderland of the physiological. Function rather than structure is the foundation of the science of medicine. A physiological problem cannot be argued from the standpoint of pure anatomy without grave danger of falling into error. The special requirements of every organ necessitate certain modifications of structure, but the basis of vital activity is the same in every part of the body. The unification of both physiological and pathological processes must be recognized. If, for example, the etiology of acute glaucoma be sought for along anatomical lines the disease will inevitably seem obscure and mysterious; but whenever it is recognized that every vital process takes place through the walls of the capillaries, glaucoma is at once brought into line with other pathological conditions which are clearly defined and well understood.

The study of the etiology of glaucoma has passed through many phases. Hypotheses deemed important in their day have had, with the advance of science and the increase of knowledge, to be put aside; but they were useful at the time in so far as they paved the way to the acquisition of fuller knowledge. The tension of the eyeball depends upon the fluid content of the globe, and the theory generally accepted is that the intraocular fluids are derived from the capillaries of the ciliary processes,<sup>1</sup> and that in a state of health a close relationship exists between intraocular pressure and general blood pressure. It has also been demonstrated that, starting from their source, the intraocular fluids pass forward through the circumferential space, the posterior chamber, and the pupil to reach the angle of the anterior chamber from which they escape from the eye into the canal of Schlemm, through the filtration spaces in the pectinate ligament. When that mechanism is in proper working order the tension of the eyeball is liable to very slight variation, consequently the intraocular pressure resembles the general blood pressure in so far as both are maintained at a fairly constant level in the normal condition; but sudden and great variations are liable to occur in such morbid conditions as glaucoma and hyperpiesia. It must not be concluded, however, that high blood pressure is in itself an essential factor in the etiology of glaucoma. The two conditions frequently coexist, but the relationship is purely accidental and is not one of cause and effect. Arterial pressure must exercise a certain amount of influence upon the tension of the eye, but the important factor in the regulation of the intraocular pressure is the pressure in the capillaries. That being so, the clue to the pathogenesis of glaucoma is likely to be found by a study of the capillary circulation in the eye.

Many of the old theories of the causation of glaucoma were based upon the hypersecretion of the aqueous humour: that hypothesis is open to serious objection. When the excretory channels in the corneo-iridic angle are in good working order any increase in the inflow of fluid is at once compensated by a corresponding increase in the outflow. The results of clinical experience, moreover, have demonstrated that when the secretion of the aqueous is excessive, this reciprocal arrangement is quite efficient in maintaining the normal tension of the eyeball. On the other hand, the pathological study of eyes enucleated as a result of secondary glaucoma has demonstrated that hardening of the eyeball is due, not to over-secretion of the intraocular fluids, but that it is the result of their retention. In almost every instance the filtration spaces at the corneo-iridic angle are closed and obstruct the outflow of fluids, which, being retained within

the eyeball, cause a gradual and progressive increase in tension.

Kries and Weber were among the first to suggest a retention theory for primary glaucoma similar to that generally adopted for the secondary form of the disease, and the epoch-making researches of Priestley Smith support their view. In the earliest stages of primary glaucoma, however, occasion for occlusion of the affected eye never arises, consequently before it is possible to obtain material for microscopic examination the disease has advanced so far that, although end-results can be fully described, nothing whatever can be learned of the mode of origin. The opportunities for observation are not much more favourable from the clinical standpoint, because the family doctor rarely sees a case until the disease is fully developed. He has had no opportunity to note the subtle changes which have led up to the acute seizure on account of which he has been consulted. Nevertheless, it is the premonitory symptoms that ought to be carefully studied, because until the mechanism of their production is properly understood it is impossible to explain how it has come about that an eye apparently quite healthy in the evening is attacked by a formidable disease before morning. It is always assumed that the eye affected was predisposed to glaucoma, and from the anatomical standpoint such a predisposition undoubtedly exists.

Priestley Smith has demonstrated that eyes liable to glaucoma are smaller than normal, and, in view of the fact that primary glaucoma is a disease of late adult life, he has pointed out that, while the lens continues to grow throughout life, the size of the eyeball, after a certain age, remains stationary. In some instances, therefore, the disproportion between the bulk of the lens and the size of the globe becomes so pronounced that the circumferential space is obliterated. Whenever that occurs increase of pressure in the vitreous chamber pushes the lens forward, and closes the filtration angle by the approximation of the base of the iris to the posterior surface of the cornea. Retention of the intraocular fluids leads to the development of symptoms of glaucoma, and these will steadily persist so long as the drainage system of the eye remains blocked. If the circumferential space has been encroached upon gradually the eye can so far adapt itself to the altered conditions, and acute symptoms do not occur, but if, on the other hand, obliteration takes place suddenly signs and symptoms of acute congestive glaucoma at once arise.

The most meticulous study of the pathological anatomy of an eye that has been excised for glaucoma can, however, reveal nothing more than end-results. An examination of the eyeball can never by itself reveal the cause of the disease. The sick body, as Lenné said, must also be considered, because, until glaucoma is brought into line with diseases whose etiology is well established, its pathogenesis cannot be properly understood. It is necessary in the first place, however, to recall the physiological principles which regulate the intraocular circulation and control the intraocular pressure. An essential postulate for the continuation of the circulation in the eyeball is that the arterial pressure be higher than the capillary, the capillary higher than the venous, and the venous higher than the intraocular. The capillaries, rather than the arteries, are the chief regulators of intraocular pressure: any obstruction to the venous outflow is of much more importance to the eye than high pressure in the arteries. This preponderating influence of venous obstruction is due, in all probability, to its immediate effect upon the capillaries. Any local interference with the venous circulation—ligature of the venae vorticosae, for example—will at once precipitate an acute glaucomatous seizure. When, however, the problem is put in its right setting and seen in its proper perspective, the behaviour of the capillaries is the one thing that is fundamental, both in physiology and in pathology. It is all-important, because the capillaries are not only the dynamic part of the circulatory system, but they also demonstrate the sum of the purposes for which circulation of the blood exists.

Bryson,<sup>2</sup> in the early days of the James Mackenzie Institute for Clinical Research, was the first to suggest that the

capillaries play the predominant role in all vital activities, and that the other parts of the vascular system are controlled by them and are subservient to their requirements. On several occasions he has brought forward clinical evidence in support of his views, and the truth of his hypothesis has been proved by many laboratory workers, among whom Krogh, Lewis, and Dale deserve special mention. These observers have demonstrated that the capillaries act independently of the other parts of the circulation; that they are called into use only as they are required, and that there is an enormous reserve of shut-down capillaries in an organ while it is resting. The capillaries and the cells associated with them may be said, therefore, to act together as a physiological unit. When the feeding time for a cell is due the capillaries associated with it open at the right moment, and after sufficient nutriment has been supplied they close down. This nutritional process goes on intermittently so far as individual cells are concerned, but constantly over the body as a whole. The result is that blood is sent round at the call of the different cells, while the utmost economy is practised in its distribution. This regular fluctuation of the capillaries is the basis of all vital activity.<sup>3</sup> It explains why it is that separate parts of an organ work in shifts—some of the component cells being in action while the others are resting, and vice versa. If all the capillaries were to open up simultaneously it is common knowledge that they could contain more than the whole of the blood in the body, and the animal would bleed to death into its own capillaries, because, stagnation having taken place, circulation would cease.

It is generally agreed that the tissue fluids come from the blood plasma by dialysis through the walls of the capillaries, and Duke-Elder has demonstrated that the intraocular fluids obey the same physico-chemical laws. He believes, therefore, that the aqueous humour is a dialysate, and has brought forward evidence to prove that it is neither a secretion nor a filtrate. His work has put the physiology of the intraocular circulation into line with the circulation in the body as a whole. That does not mean, however, that there are no local differences in special organs, but Duke-Elder believes that the apparent anomalies are to be explained by the difference in the permeability of the capillaries. Each organ has its own needs, and possesses within itself physiological adaptations for the purpose of satisfying its requirements. In carrying out this process the permeability of the capillaries is one of the most important factors, permitting only the right quantity and the proper quality of nutrient fluid to be dialysed from the blood plasma.

In the eye the capillaries are very impermeable, relative to those in other parts of the body. While, as a rule, the tissue fluids are dialysed at a pressure of from 1 to 2 mm. Hg, in the eye dialysis takes place under a pressure of about 25 mm. Hg. The aqueous, therefore, is comparable to the tissue fluids, both as regards its origin and its metabolism, but it differs from them qualitatively in proportion to the relative impermeability of the capillaries. In the eye the special arrangements may be described as a "biological adaptation to keep the intraocular fluids as far as possible optically homogeneous." That is to say, that a simple modification of the same physiological process which regulates the function of the capillaries in all the other parts of the body is sufficient to secure the transparency of the dioptric apparatus of the eye. That physiological arrangement is an apt illustration of one of the main contentions of this paper—namely, that although peculiarities of structure are necessary for the architecture of the different organs of the body, yet it is one and the same physiological process which regulates and controls their vital activities.

The first departure from health in the eye is indicated by dilatation and increased permeability of its capillaries, but except in the case of direct injury the cause of this must be sought for in the general health of the patient rather than in the eye itself. The eye is not only in the body, it is also of the body: that is the key to the proper understanding of the glaucoma problem.

Interference with the circulation of the blood through the eyeball and the consequent alterations in the composi-

tion of the intraocular fluids are the outstanding features of acute congestive glaucoma, and in every instance loss of tone in the wall of the capillaries is responsible for the onset of an attack. Of the predisposing causes, in addition to the small size of the eyeball, the most important is the wear and tear of life, with its cumulative autointoxication and its vascular degenerations, while among the causes directly precipitating an attack may be mentioned over-excitement, crushing misfortune, sorrow and bereavement, excessive fatigue, prolonged exposure to cold, repeated indiscretions in diet, or a bout of drinking. It is almost certain that glaucoma cannot occur in anyone who is quite healthy. Doubtless in many instances the disease reveals itself with appalling suddenness in one who is apparently healthy, but in every case of that kind a careful scrutiny of the patient's medical history will disclose symptoms, both local and general, which, though regarded as trivial at the time of their occurrence, were really premonitory of something much more serious. It is difficult to detect the earliest signs of failure in the delicate physiological mechanism for keeping the tension of the eyeball at a normal level. These must, however, be intimately associated with an alteration in the behaviour of the capillaries which regulate intraocular pressure, and the truth about glaucoma will not be known fully until all the factors governing the circulation, both of the blood and of the fluids within the eyeball, have been clearly demonstrated.

It is known that the body contains two groups of substances mutually antagonistic—a histamine group, acting as dilators of the capillaries, and an adrenaline group, acting as contractors. During life there must be a constant give and take between these two groups in the effort to maintain equilibrium, which is readily disturbed in one or other direction by the influence of hormones. Whenever one of these groups gains ascendancy over the other disturbance in the capillary circulation occurs sufficient to place the patient in the borderland of the pathological. Dale and his associates have made a careful study of histamine,<sup>4</sup> and have demonstrated that when this substance is injected intravenously into a living animal it causes such extreme dilatation of the capillaries that the blood stagnates and at the same time the capillary walls become so permeable that oedema of the tissues occurs from loss of blood plasma. Those changes may become so extreme that the circulation is brought to a precariously low point by depletion of the central vessels. When such circulatory disturbances are general throughout the body secondary shock arises, but when they are localized in the eyeball acute glaucoma supervenes. Both in acute glaucoma and in secondary shock, therefore, the underlying cause is the same, and from the pathological point of view one condition may be regarded as analogous to the other.

To sum up, it is probable (1) that the first stage in the pathogenesis of glaucoma is a disturbance in the capillary circulation leading to a general dilatation accompanied by increased permeability of their walls; (2) that the condition is brought about by the action of a toxin which upsets the delicately balanced mechanism controlling the function of the endocrine glands, and thereby interferes with the normal action of the sympathetic nervous system.

One of the earliest symptoms of glaucoma—one that occurs before increased tension in the eyeball has become permanently established—is dulling of sensitivity to dim light and delay in dark adaptation.<sup>5</sup> This failure in light minimum is due to interference with the function of the layer of rods and cones of the retina, which derives its nourishment from the choriocapillaris. Whenever these nutrient capillaries lose tone the blood stagnates, the rods and cones suffer, and the light sense becomes disordered.

Although severe congestive changes and oedema of the ocular conjunctiva are such outstanding characteristics of acute glaucoma, they are neither primary nor essential to the attack, but are secondary to the changes which have occurred already in the capillaries. The glaucoma is fully established before the surface of the globe has become congested; but unless the patient has consulted

his doctor during a premonitory attack, the disease is very seldom seen in this early stage.<sup>6</sup> That, however, is the time when it can be studied in its simplest form, because a premonitory attack differs from genuine glaucoma only in so far as it passes off quickly. The pathogenesis of both is the same. The congestive changes are something superadded to a pre-existing condition, and it is not difficult to understand how they originate. The increased dilatation of the capillaries and the increased permeability of their walls cause great interference with the intraocular circulation. An increasing obstruction is therefore offered to the return of the blood by the veins, and whenever stagnation occurs acute glaucoma supervenes. The phenomena seen in the eye resemble what occurs in the thrombosis of blood vessels in other parts of the body—acute pain, vascular congestion, oedema, and loss of function. The gravity of an attack is in great measure determined by the severity of those secondary vascular complications. The chief stress is felt at the corneo-iridic angle, where the circulation can be said to be strangulated, and the state of the eye may be compared to a hernia which has become strangulated. In both instances danger is extreme until the strangulation is relieved.

The initial cause of glaucoma may be traced to the injurious action of a toxin of the histamine type. It is probably of biochemical rather than of bacterial origin, and is manufactured in the course of defective metabolism due to persistent constipation, hepatic insufficiency, or renal inadequacy. There is, however, little difference in the action of a biochemical toxin and one of bacterial origin. Both cause dilatation of capillaries with increased permeability of their walls.

#### AN ANALOGY.

A good example of the action of both forms of toxin is seen in a comparison of acute glaucoma with acute glomerulo-nephritis. The ciliary processes in the eye and the glomeruli in the kidney show many features in common. The chief function of both is to dialyse fluid through the walls of capillaries, and the dialysate in both eye and kidney contains every substance present in blood plasma. There is this difference, however, that the quotient varies according to the osmotic pressure of the blood and the degree of permeability of the walls of the capillaries. With those reservations the aqueous humour may be taken as a type of every dialysate, and if the eye were supplied with a tubular arrangement similar in function to that in the kidney, the aqueous, after passing through it, would be turned into urine. Moreover, while the reaction of the normal aqueous is almost neutral, in glaucoma it is distinctly alkaline.<sup>7</sup> A change in the osmotic pressure and a diminished hydrogen-ion concentration of the blood permit an excess of sodium to pass through the walls of the capillaries. Archer found that the sodium content of the blood is diminished in glaucoma, and that observation is in harmony with the generally accepted statement that in nephritis there is a deficiency of sodium bicarbonate in the blood. Those changes lead to increase of pressure in the capillaries followed by damage to their walls, which become so permeable that they allow particles of protein to escape. The normal aqueous contains the merest trace of albumin, but Tronecos has demonstrated that in glaucoma it is present in appreciable amount. Albuminuria of the aqueous is due, therefore, to the same pathological process which gives rise to the presence of albumin in the urine, and if the eye were not specially protected by the great impermeability of the capillaries of the ciliary processes the presence of protein in the aqueous humour would be of frequent occurrence.

These widespread changes in the capillaries and in the veins must cause great increase in the size of the organ affected, and as both the eye and the kidney are enclosed within a firm capsule, increase of tension readily supervenes. When that occurs a state of glaucoma may be said to exist both in the eye and in the kidney—the abnormal pressure causing blindness in the one and suppression of urine in the other. In neither organ can function be restored until the abnormal tension is diminished, and,

in the last resort, that can be accomplished by performing iridectomy in the eye, and by stripping the capsule in the kidney.

#### PRINCIPLES OF TREATMENT.

The rational treatment of glaucoma is based on a knowledge of the same physiological principles which are so helpful in the study of its etiology. It is not possible, however, to attempt in this paper anything more than a brief and general discussion of the problem. In considering the pathogenesis of glaucoma, it has been stated that histamine and adrenaline are mutually antagonistic, and that when the histamine group of toxins predominates increased intraocular pressure arises, and will persist and become permanent if the noxious cause cannot be removed. The physiological antidote to all poisons of the histamine type is adrenaline,<sup>8</sup> which consequently is the rational treatment whenever capillaries are over-dilated and their circulation obstructed. When administered artificially adrenaline restores the circulation and prevents loss of fluid through the walls of the capillaries by improving their tone. A retrobulbar injection of about 3 to 6 minims of a 1 in 1,000 solution within a few minutes reduces the tension of a normal eye. In primary glaucoma it has a similar effect, and in some instances its use has brought about a cure of the disease. The use of adrenaline must, however, be carefully safeguarded locally. It is a very powerful mydriatic, and by dilating the pupil to the maximum might readily cause serious complications by pushing the iris into the corneo-iridic angle, thereby obstructing still further the escape of fluids from the eye. Its use, therefore, must always be preceded by energetic instillation of eserine drops to keep the pupil contracted. Treatment by adrenaline is, moreover, usually ineffective in very acute cases of congestive glaucoma, it being powerless to relieve the secondary complication due to thrombosis at the venous exits.<sup>9</sup> In these circumstances the first thing to be done is to relieve the stranglehold at the corneo-iridic angle. Sleep is Nature's cure for glaucoma, consequently the first indication in every case is to relieve pain—by the administration of morphine hypodermically, the continuous application of heat to the eye, free leeching of the temple, and eserine instillations to keep the pupil contracted. The general condition of the patient also demands attention. At the outset a calomel purge, followed, in three hours, by an alkaline saline draught, is always helpful, and ought to be repeated if necessary. The fact that intraocular pressure can be lowered by producing a hypertonic state of the blood has led Duke-Elder, following previous observers, to recommend the intravenous injection of 50 c.cm. of a supersaturated saline solution. The tension falls as a result of abstraction of fluid from the eye, but, as the treatment interferes with the whole fluid traffic of the body, it must be used with caution lest dangerous symptoms supervene from too rapid a fall in the general blood pressure.

In spite of those conservative means of treatment, however, ocular hypertension may persist, and in these circumstances operation will be required. The sole object of operation is to reduce the tension of the eye and to prevent the recurrence of hypertension. No operation can, he said to be a cure for glaucoma, in spite of the fact that thousands of sufferers, who would otherwise have been blind, have been enabled to retain their sight by the aid of one or other of the various operative procedures that have been introduced since von Graefe discovered the value of iridectomy.

The aim of every operation for glaucoma is to establish a filtering cicatrix which will act as a safety valve through which excess of fluid can escape from the eye during any recurrence of high tension. This immediate end may be successfully attained, but nevertheless the disease may progress. The treatment of the patient himself, therefore, must always be considered to be as necessary after, as it was before, operation.

## PROFESSOR CALMETTE'S STATISTICAL STUDY OF B.C.G. VACCINATION.

BY

M. GREENWOOD, F.R.C.P.,

PROFESSOR OF EPIDEMIOLOGY AND VITAL STATISTICS IN THE UNIVERSITY OF LONDON.

In the January issue of the *Annales de l'Institut Pasteur* Dr. Calmette publishes an article<sup>1</sup> on the statistics and results of his method of prophylactic inoculation from July, 1924, to December, 1927. Dr. Calmette's earlier report<sup>2</sup> was subjected to some little criticism both in the editorial columns of the *British Medical Journal*<sup>3, 4</sup> and from individual writers<sup>5, 6</sup>; recently Dr. Monod<sup>7</sup> has expressed the hope that the latest report might allay the doubts that had been expressed as to the sufficiency of the statistical evidence.

Briefly, the objections which were urged against the earlier report were these: (1) that the enormous rate of mortality from tuberculosis said by Dr. Calmette to apply to the children of the tuberculous, or to children exposed to massive infection, in the first year of life was deduced from inadequate data or depended upon misinterpretations of published literature, and did not agree with such evidence as that of Kjer-Petersen and Ostenfeld<sup>8</sup>; (2) that the positive evidence of a statistical kind supplied by Dr. Calmette was ambiguous.

Thus, with respect to the first objection, I pointed out that Weinberg's very careful statistical study had been misrepresented; that, far from supporting the suggestion that anything like 25 per cent. of the children of the tuberculous died of tuberculosis in the first year of life, Weinberg's figures were in reasonable agreement with those of Kjer-Petersen and Ostenfeld, Bergman,<sup>9</sup> and Dörner,<sup>10</sup> making the rate of mortality of the order of 5 to 10 per cent. rather than of 25 per cent. With respect to the second objection, I showed that the data handled by Dr. Biraud, who used an adequate method of analysis, became so scanty within a few months of birth that it was difficult to have great confidence in the inferences—*prima facie* favourable—which appeared to be deducible from them.

An attentive study of Dr. Calmette's latest paper leads me to think that its distinguished author has either not read or not understood the criticisms of his former report, because, to put the matter quite plainly, this new paper repeats and even exaggerates former inaccuracies while introducing statistical errors peculiar to itself. I take first the contention that Dr. Calmette has again misrepresented the published work of other writers. Of Weinberg he writes under the heading *Mortalité par Tuberculose des nourrissons de zéro à un an nés et élevés en milieu bacillifère*:

"D'autre part, une statistique (déjà ancienne, mais portant sur un grand nombre d'enfants) publiée par Weinberg, avait établi qu'à Stuttgart, de 1873 à 1889, la mortalité des enfants de zéro

à un an par tuberculose était due: pour 30, 53 p. 100 à la mère tuberculeuse; pour 29, 88 p. 100 au père tuberculeux; pour 31, 92 p. 100 à la fois à la mère et au père tuberculeux."

This passage repeats the misrepresentation to which attention had already been drawn. The figures quoted are not for the mortality from tuberculosis, but from all causes, and, at the same epoch, the death rate in the first year of life of children of mothers who were not tuberculous was as high as 23.82 per cent. The present misrepresentation is rather worse than that of the first report (p. 210), because there the attribution of the mortality to tuberculosis was not quite so explicit.

Of Kjer-Petersen and Ostenfeld's recent work (again in the section dealing with mortality from tuberculosis in the first year of life), Dr. Calmette writes that they

"n'ont enregistré, pour 245 nourrissons suivis par eux, qu'une mortalité de 7,7 p. 100 de zéro à un an. Mais il faut remarquer d'abord que les 245 nourrissons dont il s'agit ne comprennent pas seulement des enfants nés de mères tuberculeuses, mais aussi, et surtout des enfants qui ont simplement été en contact, pendant une période plus ou moins longue, avec un tuberculeux."

The mortality rate of 7.7 per cent. in Kjer-Petersen and Ostenfeld's series is the rate of mortality from all causes—namely, 19 deaths among 245 children, and of these 19 deaths only 12 were assigned to tuberculosis. The complete specification in the paper is as follows. Tuberculosis: 3 from tuberculous meningitis, 5 from pulmonary tuberculosis, 1 from abdominal tuberculosis, 1 after operation for tuberculous disease of the ear, 2 from generalized tuberculosis. The other deaths were thus classified: 1 cholera, 1 influenza and inflammation of the lung, 2 measles and inflammation of the lung, 3 inflammation of the lung. If we assume that the last three were really instances of tuberculous infection we shall reach 6.1 as the percentage death rate from tuberculous disease.

The authors set out their categories quite clearly, and one finds that 101 of the children had the mother or both parents tuberculous, and of these 101 children 4 died of tuberculosis, while the remaining 8 deaths from tuberculosis occurred among the 116 children whose fathers only were tuberculous. In other words, these data show a higher incidence of fatal tuberculosis upon the children of tuberculous fathers than upon the children of tuberculous mothers.

The fundamental importance of Kjer-Petersen and Ostenfeld's paper depends on the fact that it is based upon data compiled on statistically sound lines. Their means of access was the tuberculosis station of Copenhagen. They obtained a record of all births from July 1st, 1919, to June 31st, 1925, to families with at least one case of open tuberculosis; and they have excluded from the series instances where the child was born at least a month after a tuberculous father's death, or was isolated from the mother during the first year of life; that is, their data should give a maximal incidence for the class of population concerned. I shall return to the point later; at present I am merely describing Dr. Calmette's treatment of his sources. It is, I think, evident that no reader of his report who had not had access to Kjer-Petersen and Ostenfeld's paper (the locus of publication of which is not given by Dr. Calmette) could have formed a just impression of what these authors actually did.

The next example of Dr. Calmette's literary researches is even more interesting. On page 7 of the report under notice we are told that:

"Margarete Roepke, dans un tableau qui résumé l'histoire de 78 enfants, trouve une mortalité de 30.8 p. 100 pour les nourrissons en contact avec des malades arrivant à la période ultime de leur tuberculose; de 25 p. 100 lorsqu'il s'agissait de lésions avancées, tandis que la mortalité était nulle lors des contacts avec des formes légères de la maladie."

Dr. Calmette does not actually give a reference to the locus of publication of M. Roepke's paper, but there is no doubt that the paper in question is that printed on pages 252-263 of vol. 54 (1923) of the *Beiträge zur Klinik der Tuberculose*. The source of the above-quoted statement of Dr. Calmette is in fact the following table, which I have taken from Fr. Roepke's paper (p. 260), the only change I have made being to translate the letterpress into English.

TABLE IV.—Mortality from Tuberculosis of Infants Exposed to an Infection, in Relation to the Severity of the Disease in the Carrier of Infection.

Infants in Families with Infections Tuberculosis.	Carriers of Infection.			
	In the Last Stage.	Advanced.	Slight.	Not Reported.
Infected ... .. 23	10	7	5	1
Not infected ... .. 13	3	1	8	1
Total number of infants ... .. 36	13	8	13	2
Deaths from tuberculosis ... .. 6	4	2	—	—
Percentage deaths of exposed to risk ... 16.7	30.8	25.0	0	—

The reader will recognize in this table Dr. Calmette's percentages of 30.8 and 25, but what, he will ask, is the source of the 78 infants upon which, according to Dr. Calmette, the table is based? The answer is that if one adds up all the figures in the second column except the percentage, the sum is  $23+13+36+6=78$ ; that is, we reach 78 by counting all the children who survived twice and all those who died three times! It is not easy to understand how this mistake could have been made, because even a person completely ignorant of German and without a dictionary would surely wonder why there were four categories of absolute figures, and would have noted that 6 is 16.7 per cent. of 36, not of 78. However this may be, the simple fact is that the percentage mortalities of 30.8 and 25 are based respectively upon 13 and 8 observations.

No further remarks upon Dr. Calmette's treatment of literature seem needed. I pass now to the contention that, in the present report, in addition to repeating errors in the citation of the literature, Dr. Calmette has introduced statistical errors of a novel kind. On page 11 of the report there is a section headed "*Enfants vaccinés depuis moins d'un an au 1<sup>er</sup> décembre 1927.*" The first paragraph of this section reads as follows (italics are as in the original):

"Sur les 5,749 enfants qui figurent dans notre fichier, 3,808 ne sont vaccinés qu'après moins d'un an au 1<sup>er</sup> décembre 1927. A cette date, on avait compté parmi eux 118 décès dont 34 par maladies présumées tuberculeuses. Leur mortalité générale (par toutes causes de maladies) était donc de 3.1 pour 100, alors qu'en France la mortalité générale des non-vaccinés, avec ou sans contact tuberculeux, est de 8.5 pour 100 nés vivants. La mortalité générale de zéro à un an est donc de plus de moitié moindre chez les vaccinés en contact tuberculeux qu'chez les non vaccinés avec ou sans contact."

Now the ratio of 8.5 per cent. is the ordinary measure of mortality in the first year of life; that is, it purports to tell us—and, unless the fluctuations of natality or mortality from month to month and year to year are very large, it does effectively tell us—what is the proportion of live-born children who, being exposed to risk of death for a whole year from birth, will actually die within that year. But the 3,808 children in Dr. Calmette's report are definitely stated to have been vaccinated less than a year from the date of closing the observations. Therefore, if the record of mortality extended from birth to the first anniversary of birth it covered some part of the first year before they had been vaccinated at all; if it only covered the period during which the infants belonged to the vaccinated class it is not a record of the mortality of the whole of the first year of life, but only of a part of that year. On either hypothesis the ratio of the number of deaths to the number of children cannot be compared with the rate of mortality in the first year of life. From a consideration of the details printed amongst Dr. Calmette's documents it would appear that the second method was that adopted in compiling the data. Omitting three cases of death after the age of 1 year it is found that no less than 38.26 per cent. of the total deaths were at ages 6-12 months, and only 12.17 per cent. in the first month of life. It is well known that the greatest proportion of deaths in the first year occur in the first month of

life. Thus in England and Wales (1926) 45.38 per cent. of the total deaths under 1 year occurred in the first month of life, and only 23.28 per cent. at ages over 6 months. The explanation of Dr. Calmette's figures is presumably that he is dealing with the mortality, not from birth, but from (on the average) an older age, hence the large proportion of deaths at older ages. An elementary mistake in the handling of statistics has been made, and a mistake which would necessarily show a result favourable to any treatment.

I do not think that it is necessary to examine Dr. Calmette's statistical methods further; it seems to me to be proved that the latest report, where it differs from its predecessor, differs from it for the worse, and that it cannot be regarded as a serious contribution to scientific literature at all.

If the question were merely one of academic discussion it might well be left there—indeed, it might well never have been raised. To paraphrase Mr. Shaw, Dr. Calmette's excursion into statistics might properly have been received with that silence which falls upon ordinarily good-natured people when a man of distinction offers, as his contribution to the discussion of a matter he has never studied, an absurd blunder. But it has been suggested that those who are unable to accept these strange bibliographical and statistical methods are indifferent to the possible importance of the subject in its practical applications. As a statistician I naturally attach value to the statistical method as an instrument of research. If a scientific man claims that he has proved by some other method than the statistical that such-or-such a means of treatment is good, I am naturally not very ready to believe him; but I neither have nor claim the right to impose my belief upon others. If Dr. Calmette had stated that, on experimental grounds, he was satisfied that his method of vaccination was a valuable prophylactic, and had confined himself to the kind of reasoning contained, for instance, in the first pages and the fifth and sixth sections of his report, I should not have been convinced because, *inter alia*, I do not understand how a living vaccine—that is, something quantitatively indeterminate—can be a satisfactory means of therapeutics; but I should have felt that my knowledge of the literature and technique of modern immunology was so amateurish that it would have been an impertinence to bandy words with an investigator who has devoted his life to such studies. But Dr. Calmette has not adopted this course; he has deliberately appealed to the statistical method, and, in my submission, his use of that method has been so gravely defective that no confidence can be placed either in his statistical inferences or in the reliability of the data which he has assembled. The collection of data is at least as delicate a business as their analysis, and a writer who shows so little respect for logic in analysis is not likely to have been more circumspect in assembling data for analysis. I see no hope of obtaining statistical data from France. If an appeal is to be made to statistical methods in other countries, we should be quite clear what conditions have to be fulfilled to give the statistical court jurisdiction.

If we confine ourselves to the case of the incidence of fatal tuberculosis in the first years of life, and desire to learn whether a particular treatment applied at the beginning of life reduces the risk of death, our first difficulty is the smallness of the material. The total number of registered deaths from all forms of tuberculosis at ages under 1 year in England and Wales in 1926 was only 862, or 1.8 per cent. of the whole number, 48,757, of deaths under 1, and 1.24 per 1,000 of the total number of live births, 694,563. Suppose, then, we were to take by lot every tenth registered live birth and to divide the sample of, say, 70,000 live births into two sets of 35,000 each, to treat one moiety and leave the other as a control series. We should expect, on the average, some 43 deaths from tuberculosis in the control series, the expectation being subject to an error of sampling of approximately 6.6. If, then, in the treated series there were 23 or fewer deaths from tuberculosis, we should reasonably conclude that it was easier to believe that the treatment had really been beneficial than that a very improbably large divergence had arisen by the luck of sampling. Such a comparison, if the conditions of random sampling had been strictly fulfilled,

would be perfectly satisfactory. But in actual practice the larger the "sample" the less probable is it that the conditions will be fulfilled, and the possibility of controlling a sample of the order of 10 per cent. of the whole annual births is virtually an impossibility. Take a less ambitious scheme, and suppose that in some town of moderate size, a town of some sixty or seventy thousand inhabitants, with an annual quota of, say, 1,000 births, the children could be treated randomly—for example, every second child whose birth was registered from January 1st in some year to be treated. We should expect on the average less than one registered death from tuberculosis in the control 500, and no strong presumption of advantage would be raised by a nil return from the treated series, taking only a year's experience.

Evidently it was a sound instinct to seek for a decision amongst the class of material where a higher rate of mortality was to be expected. That is the significance of Kjer-Petersen and Ostenfeld's work. What can we conclude from their investigation as to the probable range of mortality in the first year of life of in-contacts? We can, of course, at once dismiss the preposterous suggestions of rates of mortality of the order of 25 per cent., even from all causes. Had such a rate really prevailed in the population sampled by Kjer-Petersen and Ostenfeld, their "expectation" would have been 61 deaths with a standard deviation of 6.77. Actually they observed 19, and the odds against such a deviation as 42 are of the order of a thousand millions to one. If, however, one might postulate a rate of mortality from tuberculosis in the first year of life even of the order of 5 to 10 per cent., the comparison of samples of order 500 would not be waste of time. We should expect

in our control 500 from 25 to 50 deaths, and if the treated sample returned, say, only some 15 to 30 or fewer deaths, a case would have been made out which would be rather strong. Whether it would be practically possible to use this method, here or in America, it is hard to say. The number of instances of births in families with one or more cases of open tuberculosis which come to the notice of the public health authorities within any one area and within a limited period of time is small, and the difficulty of strict random sampling is great. We are concerned, not with guinea-pigs, but with human beings, and it is not easy to induce those who have the medical charge of human beings to administer to any of them a treatment which they regard as worthless, or to abstain from administering to any of them a treatment which they regard as valuable. None of us can dramatize this conflict with the art of Mr. Sinclair Lewis in *Martin Arrowsmith*, but all of us have, to a greater or less degree, participated in it. I do not expect that the value of B.C.G. will be determined on these lines. Like most methods of treatment, its use or neglect will be determined by psychological considerations. But to the still small, but increasing, number of medical men who attach importance to statistical accuracy it is of some moment that methodological errors having the sanction of the name of a distinguished investigator should at once be pointed out. That is my reason for writing this article.

## VITAL CAPACITY IN HEART DISEASE.\*

BY

H. WALLACE JONES, M.Sc., M.D., M.R.C.P.,  
SENIOR HONORARY ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.  
(From the Heart Department of the Royal Infirmary.)

It has been the aim of investigators for many years to devise some simple test to estimate the functional capacity of the heart, apart from the subjective sensations of the patient. Many tests have been introduced from time to time for this purpose, based as a rule on the response of the heart to some form of exercise—the simplest consisting of taking the pulse rate before a fixed amount of exercise, immediately after the exercise has ended, and after an interval of a few minutes. An exercise tolerance test of this type has largely been made use of by the Ministry of Pensions for purposes of assessment of cardiac disabilities.

A test like this one, based on changes in the pulse rate, however, is open to the objection that it is more a measure of the excitability of the sino-auricular node than an indication of the capacity of the heart, and depends on many other factors quite independent of the cardiac reserve power. After vital capacity had been introduced as a measure of the extent and progress of certain lung conditions this test was applied to patients suffering from cardiac disabilities by several observers (see references 1 to 4), who found that the vital capacity was very much below normal standard when any serious cardiac condition was present; while Peabody and Wentworth<sup>5</sup> also drew attention to the fact that there was a definite relationship between diminution in the vital capacity and a tendency to dyspnoea on exertion.

Before considering the changes which occur in cardiac patients it is advisable to consider what is meant by vital capacity. Hutchinson<sup>6</sup> many years ago divided the volume of air in the lungs into the following divisions:

1. *Residual air*—air which cannot be expelled and is left in the lungs.
2. *Reserve air*—air which can be expelled by effort at the end of normal expiration.
3. *Tidal air*—air which is inspired or expired during normal respiration.
4. *Complementary air*—air which can be inspired after normal inspiration.

\* Based on a paper read before the Liverpool Medical Institution.

5. *Vital capacity*—the sum of the reserve air, tidal air, and complementary air—that is, the greatest amount of air which can be expelled after the deepest possible inspiration.

In this investigation a simple water spirometer (Fig. 1) has been used, graduated in cubic centimetres and balanced so that no effort is required to raise the cylinder. A large number of glass mouthpieces were provided, so that they could be readily disinfected between each patient without loss of time.

It is always advisable to explain fully the working of the machine before actually taking the measurement, as it is necessary to get the patient's whole-hearted co-operation to obtain an accurate result. Each patient was given three attempts, the highest being taken as the vital capacity. In taking the reading, if there is any tendency to expire through the nose this should be closed by pinching during expiration. When patients were not confined to bed the record was always taken standing, and generally in their ordinary clothes. With regard to the patients who were confined to bed they were all able to sit up in bed when taking the reading, so that it was not necessary to correct the reading for the 5 per cent. diminution in the vital capacity which has been shown by Christie and Beams<sup>7</sup> and Rahnowitch<sup>8</sup> to occur when the reading is taken in the recumbent position. Owing to the variability of the vital capacity according to the height, sex, age, and race of the individual concerned, the simple reading of the number of cubic centimetres expired gives little indication of the deviation from the normal, unless the reading is expressed in percentages of the standard vital capacity for that individual.

In this investigation the vital capacity is expressed as percentages of the standard vital capacity for that particular patient. It would be out of the scope of this paper to enter into all the different methods for calculating the

FIG. 1.—Water spirometer.

standard vital capacity; probably the most accurate is that calculated on the surface area of the body as estimated by the method of Du Bois,<sup>8</sup> where the vital capacity is two and a half times the surface area in men and twice the surface area in women. This is, however, a somewhat lengthy proceeding, and West<sup>9</sup> has shown that for all practical purposes the standard vital capacity in cubic centimetres can be determined by multiplying the standing height of the patient in centimetres by twenty-five in men and twenty in women. Age also modifies the reading considerably, but it has been shown by the work of Bowen and Platt<sup>10</sup> that this alteration with age only takes place during youth and after 50 years of age. As the cases in this series, with one or two exceptions in the high tension group, fell between the ages of 20 and 50, it was felt that the variation due to this factor would not materially alter the results.

Before investigating cardiac cases it was thought desirable to take a series of normal men and women and see what variations took place between the actual vital capacity as tested by the spirometer and the calculated standard vital capacity of the individual by means of West's formula. Fifty men, mostly medical students, and fifty women, chiefly nurses with a few students, were tested in this way.

#### Vital Capacity of Fifty Normal Males.

An examination of Fig. 2 shows that there are considerable variations among healthy individuals, and readings of 20 to 30 per

#### VITAL CAPACITY NORMAL MALES 50

FIG. 2.—Showing the vital capacity of fifty normal males. The vertical line indicates the vital capacity in cubic centimetres, the horizontal line the heights, and the oblique line the standard vital capacity for each height as calculated by means of the formula. Each individual reading is shown as a dot.

cent. above or below normal are quite common without any apparent evidence in the health of the individual. In spite of these individual variations, however, the average of the group works out at 102 per cent., which is very near the normal figure of 100 per cent.

#### Vital Capacity of Fifty Normal Females. (Fig. 3.)

The variations in this group are if anything greater than in the male group, and the number of cases in which the actual

vital capacity was much below the calculated normal are more numerous. The average for the whole group is 95 per cent.—slightly below normal.

#### The Effect of Organic Cardiac Disease on Vital Capacity. (Fig. 4.)

The percentage incidence of organic cardiac disease is shown on the vertical line and the percentage of the normal vital capacity on the horizontal line. The normal curve is taken from 100

FIG. 4.—Curve to show the effect of organic cardiac disease on vital capacity.

normal individuals and is shown by the broken line. The curve of the organic cardiac cases is taken from 50 cases and is indicated by the continuous line.

#### Readings obtained in the Various Groups of Organic Cardiac Cases.

**GROUP I: The Average Vital Capacity of all Organic Cardiac Cases.**—Most of the cases in this group were able to attend the heart department, and only in comparatively few cases were the patients confined to bed. The cases examined numbered 54; the average vital capacity was 53 per cent.

**GROUP II: The Vital Capacity of High Blood Pressure Cases.**—All over 160 mm. systolic pressure, most of them over 200 mm. Number of cases 13; average vital capacity 55 per cent.

**GROUP III: The Vital Capacity of Mitral Stenosis Cases.**—These cases are subdivided into two groups—those with normal rhythm and those with auricular fibrillation. The average vital capacity for the whole group was 47 per cent. (25 cases); for the normal rhythm group 56 per cent. (12 cases); for the auricular fibrillation group 40 per cent. (13 cases).

**GROUP IV: The Vital Capacity of Cases of Aortic Regurgitation.**—The number of cases in this group was 10; the average vital capacity 59 per cent.

**GROUP V: The Vital Capacity of Cases of Auricular Fibrillation of All Kinds.**—There were 16 cases in this group, with an average vital capacity of 45 per cent.

**GROUP VI: The Vital Capacity of Cases showing Abnormalities in their Electro-cardiographic Record.**—(1) Left ventricle preponderating—average vital capacity 50 per cent. (13 cases). (2) Right ventricle preponderating—average vital capacity 51 per cent. (5 cases). (3) Inverted "T" (ex. Lead III only)—average vital capacity 51 per cent. (7 cases). (4) Q R S abnormal—average vital capacity 58 per cent. (3 cases). (5) Auricular fibrillation—average vital capacity 42 per cent. (14 cases).

These figures show that the vital capacity is markedly diminished when any organic cardiac condition is present. In certain conditions, especially in the mitral stenosis group with auricular fibrillation, this diminution is very marked, while in the high tension cases and in aortic disease it is not relatively so marked. In the cases showing changes in the electro-cardiographic record, apart from the low reading in the fibrillation group which has already been noted there is no special change in the average reading of any of these particular groups. A series of cases were kept under observation for a considerable time to see if any change took place in the vital capacity with varying states of compensation in the same patient. In two of these cases auricular fibrillation supervened during the period of observation, and we had the good fortune to obtain records of the cases while the heart was beating with its normal rhythm and subsequently records of the same patient when auricular fibrillation was present.

The first of these cases was a man, aged 44, suffering from mitral stenosis with a slight mitral leak. Fig. 5 shows the heart rate and vital capacity of this patient for a period of two months. The

FIG. 5.—Chart showing the heart rate and vital capacity for a period of two months of a man suffering from mitral stenosis.

chart shows clearly the drop in the vital capacity which occurred with the onset of auricular fibrillation and the subsequent improvement which took place on full doses of digitalis. (I am indebted to Dr. Ince for this chart and that shown in Fig. 6.)

The second case was that of a woman aged 26, also with mitral stenosis. Fig. 6 shows the effect of rest and digitalis on the heart rate and vital capacity when the heart was beating with a normal rhythm, the pulse rate falling steadily, and the vital capacity rising. The second part of the chart shows the record obtained

FIG. 6.—Chart showing the effect of rest and digitalis on the heart rate and vital capacity of a young woman with mitral stenosis.

from the same patient when she was readmitted two months later with auricular flutter, which soon became auricular fibrillation. She was extremely distressed on admission, and the vital capacity was not taken until she had improved considerably, but even then it was very much below the lowest figure when normal rhythm was present, and though improvement took place under digitalis it never subsequently reached its previous figure.

Another interesting case of this series was that of a healthy man in whom auricular fibrillation had been accidentally induced by means of an electric shock. His heart was turned back to its normal rhythm by quinidine, but relapsed into fibrillation and again had to be turned back by quinidine. We took records of his vital capacity during the whole of the period of transition from one rhythm to the other, and at no time did the change in the vital capacity between the period of normal rhythm and the periods of fibrillation exceed 100 c.cm.—a relatively very slight change.

A series of cases of disorderly action of the heart, or the "effort syndrome," were also investigated. This group

is of special interest in view of the marked dyspnoea on exertion which, as a rule, is one of the characteristic features of this disease.

All the cases investigated were very well marked examples of this condition, and were mostly of men in receipt of a pension for this disability as a result of service in the war. The cases investigated numbered 9, the average vital capacity being 85 per cent.; the lowest individual reading was 75 per cent.

These results in cases with disorderly action of the heart are in agreement with those published by Levine and Wilson<sup>11</sup> in this country and by White<sup>12</sup> and Adams and Sturgis<sup>13</sup> in America. The very slight diminution in the vital capacity of this group is very curious in view of the marked dyspnoea which all these patients had, and shows that the dyspnoea which is associated with functional disease of the heart is very different in origin from that due to organic cardiac disease. Leaving out this group, which is in a class by itself and depends on so many factors outside the cardiac condition, it is apparent that the vital capacity is an indication of the amount of dyspnoea in cardiac disease, and though many<sup>2</sup> question that it pictures the cardiac condition more clearly than records of the blood pressure and pulse rate, and in support emphasize those cases where the reading does not change rapidly with varying states of compensation, yet there is no doubt that it is a valuable numerical expression of the amount of dyspnoea.

If one takes all the cases together they can, broadly speaking, be divided roughly into the following four classes, according to the amount of dyspnoea:

1. V.C. above 60 per cent.—dyspnoea not very marked.
2. V.C. between 60 and 40 per cent.—moderate amount of dyspnoea.
3. V.C. below 40 per cent.—considerable amount of dyspnoea.
4. V.C. below 30 per cent.—patient usually confined to bed with orthopnoea.

As in normal persons, however, a considerable amount of individual variation takes place.

Many views have been expressed as to how this diminution in the vital capacity in cardiac conditions is brought about. Siebeck<sup>14</sup> believes that it is due to engorgement of the capillaries of the lung alveoli causing distension of the alveolar walls with increase in the fibrous tissue. Drinker, Peabody, and Blumgart<sup>15</sup> have investigated the effect of pulmonary congestion on the ventilation of the lungs in cats, and have shown that pulmonary congestion produced by compressing the pulmonary veins at their entrance into the left auricle caused a marked diminution in the air passing through the lungs, and that recovery soon occurred when the pressure was released; but that if this compression was maintained for sufficient time to cause exudate into the lungs a more or less permanent diminution in the air passing through occurred. They believe that vascular congestion can act in two ways: (1) by encroaching upon the alveolar spaces by the congestion limiting their size; (2) by diminishing the elasticity of the lungs owing to the congestion, like erectile tissue.

Meakins and Davies,<sup>16</sup> in summing up the evidence, express the opinion that the decrease in cases of organic cardiac disease is probably due to some structural change in the lungs. In favour of such a change taking place is the slow alteration in the reading with changes in the degree of compensation, and also the fact that the diminution is greatest in cases of mitral stenosis, especially when associated with auricular fibrillation, a lesion which is extremely likely to produce permanent changes in the lungs.

In conclusion, I should like to emphasize the following points:

1. The vital capacity is a valuable numerical expression of the amount of dyspnoea in organic cardiac cases.
2. It is a useful indication as to the general progress of treatment, though the changes in the reading only follow slowly the varying degrees of compensation of the heart.
3. The vital capacity is most diminished in cases of mitral stenosis, especially when associated with auricular fibrillation.

4. The reading is no indication of the amount of dyspnoea in disorderly action of the heart or functional disease.

5. It is of little value in the early diagnosis of cardiac conditions, owing to the variability of normal standards.

## ORAL ADMINISTRATION OF PANCREATIC AND OTHER PREPARATIONS IN THE TREATMENT OF DIABETES.

BY

C. B. S. FULLER, M.C., M.A., M.D.CANTAB., M.R.C.P.,  
WINCHESTER.

(From the Medical Unit Laboratories, St. Thomas's Hospital, London.)

THE discovery of insulin entirely changed the former more or less hopeless outlook in cases of diabetes mellitus. It has enabled diabetic patients, who under previous conditions would have been dead before now, to lead active and useful lives in comparative good health. Such emergencies as operative and coma arising in the diabetic patient are no longer regarded with the same dread as formerly, for, in the majority of cases, both can now be dealt with successfully.

The mode of action of insulin is still a matter of conjecture, but it apparently helps to store carbohydrate in the liver and other tissues; at the same time it plays a part in the combustion of sugar. In the normal individual there is found an almost constant difference between the arterial and venous blood sugar content, the latter being less by approximately 0.04 per cent. In cases of diabetes this difference is reduced or disappears, showing an inability on the part of the tissues to deal adequately with supplies of glucose. Similarly in diabetes the lengthening of the normal blood sugar curve after the ingestion of carbohydrate shows that the liver is unable to store glycogen from the portal circulation as in the normal individual. After adequate treatment with insulin and suitable diet both these abnormalities show a return towards the normal.

It has been proved definitely that insulin is destroyed both by the gastric and the intestinal juice; whether given in acid or alkaline media, or in alcohol or glycerin, it exerts no appreciable effect on the blood sugar or carbohydrate metabolism. Oral administration on a full or empty stomach appears to make no difference; no absorption of active substance takes place. It was hoped at first that some way could be found of giving insulin by the mouth to obviate the unpleasantness of frequent hypodermic injections, but so far these attempts have not been attended with success.

In this respect insulin seems to bear a close resemblance to the extract of the posterior lobe of the pituitary gland, which on hypodermic injection has a definite effect in raising blood pressure and causing all unstriated muscle in the body to contract, whereas after oral administration it has no demonstrable effect.

Thyroid extract, when its value was first discovered in the treatment of myxœdema, was given by injection, but later it was found that it could equally well be given orally, as it was absorbed and exerted its effect in the same manner. For this reason after the discovery of insulin a fresh impetus was given to the use of various

pancreatic and other extracts for oral administration in the cases of diabetes mellitus.

The continued hypodermic injections in the case of patients on insulin treatment soon become irksome and may give rise to considerable trouble through sepsis if the patient be not careful with his cleansing of skin and syringe. In the case of the hospital class of patient the expense of the insulin very often gives rise to difficulty, though now, since the considerable decrease in price, this is not of so much importance as formerly.

These points have made it seem worth while to investigate some of the many oral preparations which are at present on the market for use in the treatment of diabetes mellitus. The claims made for these preparations are many and varied. In some cases the pamphlets even go so far as to claim cures on an ordinary mixed diet. For example, the synthetic insulin tablets A and B were said to produce a cure in a fortnight whilst the patient was on an ordinary diet. A similar claim was made for the diatana mixture.

Parko Davis's pancreatic extract (Mackenzie Wallis) is claimed to be of value in some cases of diabetes; in from two to three weeks on a suitable diet the extract is said to cause a reduction in blood and urine sugar and an improvement in the patient's clinical condition. Messrs. Parko Davis state that if no improvement is found in from two to three weeks the treatment should be discontinued. The improvement alleged in some cases might quite well be due to the strict dieting, and not to the pancreatic extract at all. They state that they do not aim at reducing the blood sugar to the region of 0.1 per cent., but they endeavour to reduce the blood sugar to the region of 0.15 to 0.20 per cent., and to decrease the sugar in the urine. No reference is made to the effect on the ketone bodies, which are in many respects of more importance in estimating the patient's condition than the amount of glycosuria.

Messrs. Carnrick, in their literature relating to the pancreatic extract put on the market by them, give a graph showing the blood sugar and urine sugar in a case treated on their preparation. In this case the sugar disappeared from the urine and the blood sugar fell to normal in a few days. They state, however, that the patient was placed on a restricted diet, presumably at the same time as he started taking the pancreatic extract, so that the fall in blood and urine sugar may have been due to the restricted diet. Indeed, in the light of my observations (recorded later) there is little doubt that the diet was the only effective factor.

Another point which must be considered is the fact that diabetes is well known to vary from time to time, and that temporary improvement may occur apparently spontaneously.

Various claims as to the exact method of action of pancreatic preparations for oral administration are made by the vendors. In most cases these claims are rather vague, and generally state or infer that the active component is insulin. These assertions must obviously be wrong, as insulin is destroyed rapidly in the stomach and intestine. It is, however, possible that there may be some other substance, not insulin, present in these preparations which, when administered orally, may be absorbed and stimulate some mechanism which controls carbohydrate metabolism in the body.

It has been found experimentally in dogs that if the pancreas be completely removed, injections of insulin will only keep the dog alive for a short period. If, however, a very small portion of the pancreas be left, insulin injections will keep the dog alive for an indefinite period. This rather points to the fact that the pancreas may secrete some other internal hormone besides insulin, and it is conceivable that this substance, whatever it may be, might be present in the oral preparations and might be absorbed from the alimentary tract when administered by the mouth. If this were so it might benefit cases of diabetes to be treated with these preparations, even though, of course, they were not absorbing any of the insulin contained in the preparations. All kinds of theories could be formed as to the type and mode of action of this pancreatic secretion, but as its presence is a pure hypothesis, conjectures as to its

mode and site of action seem rather far-fetched. As several cases which have been under my care seem to show that this substance, if present, is not at any rate absorbed in sufficient quantity to be observable clinically, the question becomes even less worthy of consideration.

Insulin seems to be rendered inert very rapidly by gastric and intestinal juices, but alcoholic extract of insulin has been found to produce a slight effect on the blood sugar when given by the mouth, and this is presumed to be due to the rapid absorption of part of the insulin with the alcohol before the gastric secretion has had time to destroy it. From the practical point of view this method is of little value, as the percentage absorbed is too small to make it a satisfactory proposition from the economic standpoint.

It is claimed for most of the pancreatic extracts that they increase the percentage of the food absorbed during digestion. If this be so it seems to be a disadvantage rather than an advantage, because the fault in diabetes lies not in the absorption, but in the utilization of the food after absorption. If we increase the absorption we increase the amount of materials with which the body has to deal, thereby throwing a greater strain on the carbohydrate metabolism. It is well known that it is exceedingly difficult to get diabetic patients to adhere for any length of time to a very rigid diet, and this would increase the difficulty; at the same time, any action of this kind would tend to diminish the bulk of the faecal matter, which is a disadvantage.

It is possible that these pancreatic extracts given by the mouth may stimulate some internal secretion other than insulin which aids in the utilization of carbohydrate within the body, and if this is the case the effect would be reflected in the blood sugar estimations and in the general condition of the patient. On these grounds it was determined to give these preparations a trial under standard conditions to see if they did produce any alteration in the patient's condition.

Some difficulty was found in finding suitable patients on whom to test these preparations, as an endeavour was made to get some mild and some moderately severe cases. Unfortunately some of the latter, whilst they were being standardized on a comparatively low diet, showed symptoms of the onset of diabetic coma, and had to be placed on insulin to prevent their condition getting worse. This has somewhat reduced the number of cases treated on these preparations, but the evidence of those cases in which the treatment was carried through is extremely constant.

In carrying out the investigations each patient was placed on a moderately low diet—say, 980 or 1,050 calories in most cases. The twenty-four-hourly collection of urine was examined daily, the total sugar and acetone being estimated; after the excretion of sugar had been constant in amount for several days the oral preparations were administered for periods of a week to a fortnight, controlled by daily estimations. In some cases preparations containing pulvis cretae or pulvis cinnamomi were made similar to the real preparations, and these were administered without the patient knowing of the substitution. This was done after the real preparations had been administered over a period of several days in order to rule out any psychological factor which might be influencing the results. In other cases sugar tolerance curves were done on the blood, first of all without and then following a large dose of one of the preparations. The sugar estimations on the urines were done by Bertrand's method, and the acetone estimations by acid distillation method, whilst the blood sugars were estimated by MacLean's method.

The following case is typical of a number in which the various preparations were employed. Details of these cases are unavoidably omitted owing to lack of space. The results were similar in all the cases.

A single man, aged 38, was admitted to hospital on October 25th, 1923. All his family had been healthy. The patient had had mumps, diphtheria, measles, and whooping-cough as a child. He was rejected for the army owing to his eyesight and varicose veins. Five years ago, when working in Canada, he noticed that he always felt tired, was thirsty, and had a nasty taste in his mouth. His doctor told him he had diabetes, and gave him a diet, to which he kept more or less for three years, since when he had not dieted. In August, 1923, he had a return of his original symptoms. In addition he lost 2st. in

weight, and had numbness and pains in the legs and marked hunger. On admission no definite physical signs were found. The urine was acid, specific gravity 1030, sugar and acetone present.

He was first placed on a diet equivalent to 1,050 calories, and then starved, and worked up gradually to a diet consisting of 51 grams of carbohydrate, 61 grams of protein, and 33 grams of fat, with a total calorific value of 980. On November 22nd, 1923, he started to take 5 capsules of Carnrick's internal secretion of pancreas 3 times a day before meals. On December 4th he started taking 10 capsules three times a day, and two days later 20 capsules three times a day. On December 11th the patient commenced to take 5 imitation capsules, containing pulvis cretae, three times a day, and on December 14th he was given 10 units of insulin twice daily, his diet being altered to carbohydrates 40 grams, protein 56 grams, fat 184 grams.

The patient felt weak when on the low diet, but said he felt much stronger when he started on the capsules. When taking the larger number of capsules daily he did not feel so well, and complained a lot of flatulence, but he said that he felt very well indeed while taking the capsules of pulvis cretae. His weight fell during starvation, but just before starting the insulin his weight was 8 st. 5 lb., the same as on admission.

The patient was discharged from hospital on January 5th, 1924.

#### CONSIDERATION OF RESULTS.

From the clinical point of view none of the cases showed or felt any improvement in their general condition whilst having the various pancreatic extracts; in fact, two patients complained of feeling weaker while on the extracts. One of these patients had to be rather hurriedly put back on insulin injections, as he developed a rapid pulse, went off his food, complained of abdominal discomfort, and became drowsy, with breath smelling of acetone. In fact, he exhibited the premonitory symptoms of coma.

Three patients were treated with Parke, Davis and Co.'s pancreatic extract (Mackenzie Wallis). One of these, a married woman, aged 35, showed little alteration in her blood sugar levels whilst taking the tablets; the glycosuria, on the other hand, possibly showed a fall at the start, but for the last few days before ceasing to take the tablets had returned practically to the original level. The acetonuria, on the other hand, tended to rise rather than fall during the exhibition of the tablets. As far as can be seen this patient was not influenced by the administration of

the tablets, and her blood sugar remained between 0.25 and 0.30 per cent. After being put on insulin injections and an increased diet she improved very rapidly, and has since done extremely well. This patient's blood sugar estimations, done at hourly intervals, showed a greater variation when she was taking the tablets. As far as can be seen from this case, one of moderately severe diabetes, the patient was not in the least benefited by the administration of the pancreatic extract.

Another of these patients, a married woman, aged 53, said she felt better whilst taking the tablets, but she also said so whilst she was having the imitation capsules containing *pulvis cinnamomi compositus*. Her acetonaemia and blood sugar curves showed little alteration. The urinary sugar also was little affected whilst taking the tablets. After being placed on injections of insulin and a much increased diet, consisting of carbohydrates 56 grams, protein 63 grams, and fat 182 grams, her acetonaemia and glycosuria disappeared in about a week and her resting blood sugar fell to between 0.100 and 0.150 per cent. She has since kept very well. While this patient was taking the imitation capsules the blood sugar finished at a higher level than at other times, but at one period fell to a lower level. From the other data, too, this patient was not materially affected by the exhibition of the pancreatic extract.

In the third patient the curve after the pancreatic extract rose to a higher level than it did when no extract was being given, but the final reading two and a half hours after the glucose was slightly lower than in the curve when no capsules were taken. These variations were of no significance.

With regard to the patient whose case is recorded in the text, during the period while he was taking the capsules the glycosuria reached its maximum when he was taking the largest number of capsules—that is, sixty a day—and the blood sugar was also highest at this point. Whilst taking the capsules the blood sugar and glycosuria levels did not appear to be appreciably altered, and the blood sugar remained above 0.200 per cent., even on the low diet he was then having. Immediately after being placed on insulin the blood sugar fell to the region of 0.150 per cent., in spite of an increased diet. The first blood sugar curve, taken while the patient was on diet alone, showed a lower resting blood sugar level, but a higher level at 2 p.m. than either of the other two curves. The second curve, taken while the patient was having five capsules three times a day, showed a very marked rise after breakfast to over 0.300 per cent. There followed a marked fall, and at 2 p.m. the sugar concentration was about 0.240 per cent. The last curve, taken while the patient was having fifteen capsules three times a day, showed a high resting blood sugar, 0.270 per cent., but the readings then kept lower, ranging between 0.220 and 0.250 per cent. Possibly this last curve shows a lower average level than the other two, but it must be remembered that the blood sugar curves vary in the same person from day to day, and there is no real improvement in the average level in spite of the fact that the patient was taking the enormous number of forty-five tablets a day, a number which it would be difficult to get a patient to continue taking over a long period of time.

A fifth case, that of a labourer, aged 26, was a severe and long-standing one, with considerable emaciation and marked asthenia. He was on diurnal injections of insulin and a diet of 40 grams of carbohydrate, 56 grams of protein, and 186 grams of fat for six weeks before the exhibition of the capsules, and improved considerably in his general condition. He was receiving 25 units of insulin night and morning, but this was stopped for a period and the patient then given five capsules of Carnrick's internal secretion of pancreas three times a day before meals. On examining the blood sugar, glycosuria, and acetonaemia estimations it was found that on ceasing the insulin injections there was a very marked rise in glycosuria, acetonaemia, and to a less extent in the blood sugar levels. At one period while he was taking the tablets the patient was excreting as much as 5 grams of acetone bodies daily in the urine. Immediately after recommencing the injec-

tions of insulin the glycosuria and acetonaemia fell rapidly, and the blood sugar dropped to nearly normal limits.

Another patient, a girl, aged 15, was given some synthetic "insulin" tablets. The tablets were divided into two kinds, A and B, and these were supposed to be taken alternately every two hours, six in all being taken during the day. While the patient was taking the tablets there was no improvement in either the glycosuria, acetonaemia, or blood sugar levels, but before discharge on 5 units of insulin twice daily her urine was free from sugar and acetone, and her blood sugar had fallen to the region of 0.100 per cent.; she had put on weight and felt very well in herself.

The last patient was a man, aged 49, with a history of diabetes for seventeen years and a ten days' history of a patch of superficial gangrene on the right big toe. He was placed on a liquid preparation called "diatana," which was credited with curing diabetes on any diet in a fortnight. Later on he did well on insulin.

In considering the various cases together from the point of view of results, the value of the different varieties of treatment must be looked at from several aspects.

In the first place, are they a cure? In no instance has there been any evidence of cure, but in the case of most of the preparations no claim that the treatment would produce a cure was made.

In the second place, is there any evidence that the treatment was beneficial to the patient? In no case is there definite evidence of any improvement whatever whilst under treatment. The patients either remained stationary or tended to go downhill, in spite of the fact that most of them were on low diets, which would have been quite insufficient for them to live and work on outside. The labourer whose case is referred to, who was on a sufficient diet to get on with outside, after being on capsules for five days had to be hurriedly put back on insulin injections owing to the fact that he was in the early stages of diabetic coma.

In June, 1923, a married woman with diabetes, who was being treated on a strict diet and Parke Davis's pancreatic extract (Mackenzie Wallis), was admitted to hospital in coma. With injections of insulin and other appropriate treatment she was able to leave hospital later comparatively well.

Besides the above, many patients have been treated at St. Thomas's Hospital with pancreatic mouth preparations during the last two years. In no case was the slightest benefit produced.

#### CONCLUSIONS.

From the consideration of the data given it is clear that the administration of oral preparations of pancreas in severe cases of diabetes is a waste of time, and likely to be harmful to the patient by delaying the proper treatment with diet and insulin injections. Other mouth preparations, such as "insulin synthetic" and diatana, I have found to be useless.

As regards the milder cases, in none of the above patients could any definite improvement be traced, either in the clinical condition of the patient or in the blood sugar levels. In those patients on whom blood sugar curves were taken over several hours no definite difference in the mean blood sugar level could be detected as the result of treatment with oral preparations. In fact, all the above results point to the conclusion that the oral preparations tried are of no value in the treatment of diabetes, and that probably the improvement attributed to the oral preparations has in reality been due to the strict diet the patient has been put on at the same time. In other words, the patients would have done equally well if put on the diet alone. The only value the tablets seem to possess is that some patients, if placed on a strict diet alone, feel that they are not receiving proper treatment, and the giving of the oral preparations obviates this difficulty.

I am indebted to Professor H. MacLean for his kindness in allowing me to carry out these investigations in his wards, and to Dr. C. H. Budgo for his help with the laboratory work.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### MASSIVE DOSAGE WITH INSULIN.

THE interest of the following case lies in the unusually large amount of insulin that was necessary to produce any noticeable improvement.

On the evening of September 20th, 1927, a baker, aged 23, was admitted to St. George's Hospital in a semicomatose condition; he was very drowsy and apathetic, and it was only with the greatest difficulty that he could be persuaded to answer any questions. An examination of his urine revealed a very considerable quantity of sugar, together with acetone and aceto-acetic acid. His breath smelt strongly of acetone.

He was immediately given 15 units of insulin and put on Graham's diet (first day). The next morning a blood sugar estimation showed 0.317 gram per 100 c.cm. Massive dosage with insulin was then carried out, carefully controlled by frequent blood sugar estimations as detailed below. All the estimations were done by Hagedorn and Jensen's micro-method.

#### September 21st.

6.45 p.m.: Insulin 60 units.  
8.15 p.m.: Blood sugar 0.370 gram per 100 c.cm.  
Patient's condition same as on admission.  
9.45 p.m.: Insulin 50 units.  
11.15 p.m.: Blood sugar 0.340 gram per 100 c.cm.  
11.30 p.m.: Insulin 50 units.

#### September 22nd.

12.15 a.m.: Insulin 120 units.  
Coma becoming deeper.  
12.30 a.m.: Blood sugar 0.530 gram per 100 c.cm.  
1.40 a.m.: Blood sugar 0.550 gram per 100 c.cm.  
2.45 a.m.: Insulin 180 units.  
3.40 a.m.: Blood sugar 0.365 gram per 100 c.cm.  
Slight improvement.  
11.15 a.m.: Blood sugar 0.335 gram per 100 c.cm.  
11.45 a.m.: Insulin 100 units.  
2.10 p.m.: Blood sugar 0.365 gram per 100 c.cm.  
2.15 p.m.: Insulin 200 units.  
3.45 p.m.: Blood sugar 0.278 gram per 100 c.cm.  
4.15 p.m.: Insulin 200 units.  
5.45 p.m.: Blood sugar 0.262 gram per 100 c.cm.  
6.30 p.m.: Insulin 500 units.  
9.0 p.m.: Blood sugar 0.227 gram per 100 c.cm.  
Condition definitely improved.  
9.15 p.m.: Insulin 200 units.

#### September 23rd.

1.20 a.m.: Blood sugar 0.182 gram per 100 c.cm.  
10.45 a.m.: Blood sugar 0.090 gram per 100 c.cm.

Thus it is seen that he received in all 1,715 units of insulin in thirty-six hours.

His subsequent treatment was briefly as follows. He was worked up the ladder diet: no insulin was given till the sixth day, up to which time his urine had remained sugar-free. He was then put on insulin again and the diet increased up to the tenth day with supplements to equal a calorific value of 1,805 C. His basal metabolism had previously been estimated at 1,820 C. From October 3rd to November 20th it was found necessary to give him on an average 200 units a day to keep his urine sugar-free.

On October 1st he was found to have marked signs of pulmonary tuberculosis in the right chest, bacilli being found in his sputum. A radiogram showed that it was only the right upper lobe that was affected, and it was decided to perform an artificial pneumothorax on that side. Considerable difficulty was experienced owing to the presence of multiple adhesions. The element of sepsis must have contributed to the abnormal resistance to treatment. In addition to the presence of tuberculosis, both his arms and legs, on admission to hospital, had been covered with a multitude of small rounded ulcers in various stages, caused apparently by the injections he had been giving himself.

His dose of insulin was subsequently reduced, and he was discharged from hospital on December 13th, having gained over a stone in weight, and being able to maintain himself on a sufficient diet with the help of 110 units of insulin per diem.

I am indebted to Dr. J. S. Collier for the permission to publish the notes of this case.

HAROLD A. BYWORTH, B.M., B.Ch.Oxon.,  
London, N.W.3. Late House-Physician, St. George's Hospital.

#### FULL-TIME ABDOMINAL PREGNANCY: PROLONGED SUPPURATION: RECOVERY.

THE following case seems to be of sufficient interest to place on record.

In August, 1927, an African woman, about 25 years old, was brought to me with the following history. About August, 1924, the patient became pregnant for the first time. In April, 1925, she had labour pains, but "nothing was born." The pains ceased after a day or two, and the patient was left with a hard swelling in the abdomen. The swelling caused only a little inconvenience until

August, 1926, when it became very painful, increased in size, and finally burst in the region of the umbilicus, discharging a quantity of foul-smelling pus. About the same time the patient noticed pus in the stools. At intervals the swelling continued to discharge pus in which were noticed short hairs and small fragments of bone.

**Condition.**—The patient was extremely emaciated, scarcely able to stand unaided, and quite unable to stand erect because of a large hard and rounded swelling in the middle of the abdomen. The swelling was discharging thin pus through a small opening about half an inch above the umbilicus. Her pulse was 120, and her evening temperature 100° F.

**Operation.**—The swelling was incised in the middle line. A fold of peritoneum was accidentally opened for about half an inch in the upper part of the incision, but was swabbed with acriflavine and closed. The cavity contained the fetid remains of an apparently full-time foetus. The cranial bones were lying loose, the brain having liquefied. Several limb bones were lying loose, but the greater part of the soft parts were still recognizable. The cavity passed downwards towards the left iliac fossa, and apparently opened into the pelvic colon. The cavity was emptied carefully, irrigated with warm saline, swabbed out with acriflavine, and drained through a large rubber tube below the umbilicus. On the second day after the operation some faeces were passed through the drainage tube and continued in diminishing quantity for fourteen days. The patient's general condition commenced to improve immediately. After six weeks she was able to attend as an out-patient, and two weeks later was soundly healed, and was discharged quite fat and well.

#### HYDATID CYST IN THE HEART.

THE illustration, supplied by the South African Institute of Medical Research, Johannesburg, depicts a hydatid cyst (c) situated in the septum of the heart in the region of the bundle of His. The specimen is in the museum of the Institute, and the interior of the left ventricle is here displayed.

The man from whom it was taken was a patient of Dr. Andrew Watt, who gave me permission to use his notes.

He had two attacks of unconsciousness while in hospital, both lasting about a minute and accompanied by fit movements. Dr. Watt identified one of them as being due to ventricular standstill. The electro-cardiograph gave no evidence of heart-block between the attacks. On other grounds a diagnosis of cerebral tumour was made. Before operation another attack of unconsciousness occurred, in which the patient died. On post-mortem examination the condition of the heart depicted here was shown, and also hydatid cysts were found in the cerebrum.

The septal lesion had evidently an intermittent effect on the conducting tissues, and recalls the case of intermittent heart-block published by Russell Wells and Wiltshire, in which the lesion was a large calcareous mass in a similar position.

Honorary Assistant Physician, Johannesburg  
General Hospital.

### MERCURY SALICYLATE INJECTIONS IN CHRONIC ULCERATION.

THE following details of the successful treatment of a very intractable ulcer of the leg by intraosseous injections of mercury salicylate seem to deserve recording.

A man received, in 1918, an abrasion of the inner side of the right ankle while assisting in the cleaning of a foul sewer; some septic material infected the cut surface. Several small painful pus-discharging ulcers formed, and in a short time coalesced into a single ulcer about the size of the palm of the hand. Despite various forms of treatment the ulcer did not improve. The veins were not varicose. I first saw him in February, 1921, and treated the ulcer in the usual way with rest, antiseptic lotions, ointments, and strapping. During the years 1921 to 1925 the patient was not under my observation from the months of May to October, as he was engaged as chef in various hotels. In April, 1925, he was treated at St. John's Hospital, Leicester Square, where his Wassermann reaction was found to be negative. During treatment in this hospital the ulcer partially healed, but broke down ten days after discharge, becoming as large as before.

In March, 1926, I injected twice weekly for a fortnight into the gluteal muscle 1 grain of mercury salicylate ("Glaseptic" ampoules 1 c.cm., Parke, Davis and Co.). The patient then left the town and I did not see him again until last October, when I found the ulcer perfectly healed with a healthy non-adherent scar. He told me that the healing process had been complete three weeks after the injections.

I showed the patient at a meeting of the Southampton Medical Society. This treatment was suggested to me in a paper read to this society by Dr. Budd Ferguson of America a few years ago.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### GLOUCESTERSHIRE BRANCH.

##### High Blood Pressure.

At a meeting of the Gloucestershire Branch at the Royal Infirmary, Gloucester, on April 12th, with the president, Mr. C. L. COODE, in the chair, Dr. H. CAIRNS TERRY opened a discussion on blood pressure.

Dr. Terry contrasted the clinical picture which used to be conjured up by the mention of high blood pressure—a plethoric man with thick arteries, albumin in the urine, and a probable history of alcohol and syphilis—with the type of case seen now, when frequently no toxic condition could be found. He almost felt justified in defining high blood pressure as a disease. He reminded his audience of the structure of an artery, with its outer fibrous coat, its inner coat composed mainly of unstriated circular muscle fibres and elastic tissue, and its intima, consisting of endothelial cells and elastic tissue. The coat to which he attached special importance was the inner muscular coat; it was always ready to act, was always having calls made on it to regulate the circulation, and its work was governed by the manner of life of the individual and the consequent varying demands made on the contractile power of the arteries. In Dr. Terry's opinion, by far the heaviest demands were made by the person always "on the go," always at tension, and giving himself no rest, even though the muscular work entailed might be in no way excessive. Such an individual tended to call too continuously on his circulation; a stage of muscular irritability in the arteries was reached, the elastic fibres began to fail to support the muscular, the muscle passed into a state of "tone," and high blood pressure resulted. As such a person grew older the muscle developed chronic spasm, the pressure rose to overcome it, the heart tried to compensate, and a vicious circle was established. Then appeared true arterio-sclerosis—degeneration in muscle which was tired out by overaction. As an example of the earlier stage Dr. Terry mentioned a man, aged 33, who came to him complaining of brain fag, which he had tried to counteract by the "fetish of fresh air and exercise." This man led a very active life, and his condition was due to interference with his circulation, the highly specialized cells in the brain being the first to exhibit symptoms of insufficient blood supply. The systolic blood pressure was over 200 mm. Hg, and even at that pressure the brain was suffering from relative starvation. In such a case the first essential was rest. Drug treatment

for lowering the pressure was illusory, and the rest must be absolute; the patient must be put to bed and kept there till it was clear that the pressure had fallen to his normal. The only drug treatment recommended was small doses of bromide or luminal to help to secure the patient's co-operation in attaining a sufficiency of rest; such patients were among the most difficult to keep in bed. In this case the blood pressure fell to 130 mm. Hg, and remained there; the patient had become perfectly fit. In its more aggravated forms the interference with cerebral circulation might produce a condition precisely simulating a haemorrhage. A woman, aged 72, intensely active in spite of her years, visited the Wembley exhibition and explored it thoroughly. Two days later she suddenly became unconscious, with incontinence and complete hemiplegia. Her blood pressure was 240, but there was no albumin in the urine. She rapidly recovered; in ten days her blood pressure had fallen to 160, and she was to all intents and purposes well. The attack left no ill effects, and she regained perfect health. The prognosis in high blood pressure depended upon the amount of fall in response to rest and the condition of the heart. If the heart was enlarged, dilated, and irregular, the outlook was much more doubtful. If albuminuria was present then the patient was heading for true arterio-sclerosis and all that that entailed.

Dr. ALLMAN POWELL mentioned the help which might be obtained from a study of the blood pressure in estimating operative risk, and gave illustrative examples.

Dr. SOUTAR discussed the effect of emotion on blood pressure, the heightened pressure due to this cause aggravating the emotional condition, until Nature could no longer stand the cumulative strain, and a crisis was precipitated.

Dr. ANNOTT DICKSON emphasized the point made by Dr. Terry that it was the muscular coat of the artery which counted in affecting blood pressure. Nearly twenty years before he had conducted an inquiry into the incidence of thickened arteries in coal miners. Among 500 men examined the very great majority had thickened arteries; this occurred at all ages, from 15 upwards. Although very thick arteries, which could be rolled under the fingers like a pencil, were frequently met with, high blood pressures were almost unknown. The explanation was forthcoming when, after a pit disaster, it was possible to obtain portions of the radial artery from a number of men who had been previously examined. It was found that the thickening was confined almost entirely to the intima, which in several cases was ten times as thick as the normal—a condition not previously described. This variety of thickening apparently did not influence blood pressure, though the lumen of the vessel was greatly encroached upon.

##### Clinical Cases.

Mr. J. F. H. STALLMAN showed two cases of congenital torticollis after open operation. He condemned the subcutaneous division of the muscle, since this left the deep cervical fascia and other structures untouched, with a consequent poor result. He demonstrated the type of harness which he fitted, and detailed the after-treatment, including daily manipulation and exercises.

He also showed a boy, aged 9, who last August sustained a supracondylar fracture of the right humerus. When first seen by Mr. Stallman in the following month a hard mass could be felt in the antecubital fossa which was diagnosed as myositis ossificans; this was confirmed by x-ray examination. Treatment by ionization and radiant heat, combined with rest in a sling, proved valueless, and if was only after prolonged rest in plaster that the condition cleared up. A series of x-ray films demonstrating the gradual disappearance of the bony mass was shown. Mr. Stallman drew attention to the danger of this condition developing in the region of the elbow-joint, with special reference to operative treatment, too early movement, or too heavy massage.

In reply to the President, Mr. STALLMAN added that the danger existed also in cases of dislocation, and that in his opinion all injuries round the elbow-joint should be treated by prolonged immobilization in the flexed position, preferably in plaster.

Mr. STALLMAN next showed a case of spastic paraplegia

in a boy, aged 11, who last June was carried into his out-patient department totally unable to stand or walk.

Photographs were shown illustrating the scissor-leg deformity of the limbs and the equinus deformity of the feet. The anterior division of the obturator nerve was divided in the groin, and the position of the limbs was corrected by suitable appliances. The boy was now able to walk unaided, though with a spastic gait.

## Reports of Societies.

### OBSTETRICS AND GYNAECOLOGY.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on April 20th, with the president, Mr. COMYNS BENKLEY, in the chair, Professor BLAIR BELL read a paper on the malignant functions of the chorionic epithelium. He expressed the belief that chorion epithelium was malignant in nature, though normally under control. Since the trophoblast was the earliest functioning tissue in the fertilized ovum, the specific process of malignant neoplasia consisted of a reversion of the differentiated, highly specialized, somatic cell to, or towards, the earliest type of cell capable of obtaining nutriment for itself; this process was known as dedifferentiation. Professor Blair Bell then proceeded to show that dedifferentiation was an essential feature of somatic malignant neoplasia, and that the placenta, or more exactly the chorionic epithelium, was a malignant tissue in respect of its functions. He referred to the work of Warburg of Berlin, demonstrating the importance of glycolysis in the metabolism of malignant tumours. The speaker then described his own investigations of human placental tissues.

Mr. R. H. PARAMORE, in a paper entitled "Eclampsia and its treatment: an experience with spinal anaesthesia in one case," discussed critically the various forms of treatment of this condition. He outlined his own theory as to the causation of eclampsia, and criticized several of the current views. He then described a case successfully treated by spinal anaesthesia, and expressed the opinion that the lateral position was most important in this procedure.

Mr. C. D. READ showed a specimen of a teratomatous ovarian tumour with torsion of the pedicle in a girl aged 11. Microscopical investigation showed areas of plasmoidal masses, large multinucleated cells lining a blood sinus, and many polygonal cells derived from Langhans's layer. The patient a few weeks later developed a tumour in the parotid gland and died within a fortnight after attacks of profuse haemoptysis. Mr. Read also showed a specimen of malignant change in the corpus uteri demonstrating metaplasia. This was obtained from an unmarried woman, aged 34, who had complained of uterine haemorrhage for more than a month. Microscopical investigation showed two different conditions. The upper mass in the uterus exhibited glandular hyperplasia with slight invasion of the muscle coat. The columnar cells had become stratified and embryonic in character in part, and the lower area presented an appearance not unlike that of a squamous epithelioma. This specimen was discussed by Professor Blair Bell, who gave an epidiascope demonstration of metaplasia in tissues.

### MYOPIA IN CHILDHOOD.

At a meeting of the Brighton and Sussex Medical-Chirurgical Society on May 3rd, the president, Dr. DONALD HALL, in the chair, Dr. C. G. SCHURR read a paper entitled "Myopia in childhood," illustrated by lantern slides.

Dr. Schurr said that his aim was mainly to try to prove that myopic children presented a problem as important to the general practitioner and ophthalmologist as those diseases which showed definite fundus lesions, such as nephritis and diabetes. After a brief description of the main features of myopia he passed to the consideration of its incidence, and said that it commenced considerably earlier than was generally supposed. Patients were met with as early as 6 years old who had acquired myopia, and congenital cases were sometimes found. Occurring

alike in males and females, myopia was most prevalent in children attending State schools, who constituted 90 per cent. of all children between the ages of 7 and 14. In America 40 per cent. of the children in State schools became myopic during their period of education, and the impression gained from observation was that the case was similar in England. When the serious results from breakdown in after-life were considered, it was clear that there was a really grave problem which, so far, had attracted insufficient attention generally. The four theories most widely held as to the causation of myopia could be divided into two classes—"postural" and "predisposition." The "postural" theories attributed the condition to (1) excessive convergence, and (2) the effect of gravity. The "predisposition" theories cited (1) a small ciliary body, and (2) diminished resistance of the sclera. An examination of the first three theories showed that in the end they were dependent upon the fourth. All three conditions might be contributory, but without an abnormal distensibility of the sclera they could not be deleterious in their action. In discussing the fourth theory Dr. Schurr said that heredity might undoubtedly be a contributory cause, but it did not account for those cases, which were by no means infrequent, in which there was no history of myopia, but, on the contrary, there was even a history of hypermetropia in the family. An investigation of the height and weight curves of myopic children in the Barclay Home, Brighton, showed that there seemed to be some definite relation between myopia and metabolism. A series of graphs of contrasting cases, with which Dr. Schurr illustrated this point, showed that where the myopia was found to be increasing there was always a falling off in the weight and height ratio compared with the normal. This condition was not found where the myopia was stationary, even if corneal nebulae were present. The material available so far had not proved sufficient for any firm conclusions, but it afforded a basis for interesting speculation; it was insufficient also for an adequate series of "ponderal indices." On the other hand, it gave very good grounds for the suggestion that the cause of myopia might be found in a consideration of aberration of growth in children. If refractive errors fell into a medical category this constituted the strongest argument, and one which so far had not been used, against allowing opticians to prescribe glasses. A description of the work in a myope class brought forward the question of the future of the children after they left the schools. The establishment of workshops, where myopes could compete with persons of like disability, appeared to be more reasonable and less wasteful of money than sending them out to compete with normal persons. Dr. Schurr emphasized the point that the early detection of myopes was a most important duty of medical officers in charge of schools; the general practitioner could give useful advice on such matters as suitable exercise, good food, sufficient sleep, and the choice of profession.

At a meeting of the Forfarshire Medical Association at University College, Dundee, with the vice-president, Dr. G. W. MILLER, in the chair, Professor J. A. KYNOCHE, in the course of a paper on the malignant complications of uterine fibromata, said that fibroid tumours were not the benign innocent growths they were once supposed to be; they might be associated with malignant changes, either in the tumour itself or in the uterus. This had a direct bearing on treatment, for if it could be shown that malignant complications occurred at all frequently it would be a weighty argument for early removal of fibroids. The cases fell into three groups—namely: (1) sarcomatous degeneration of the tumour; (2) fibroids associated with adenocarcinoma of the body; and (3) fibroids associated with squamous-celled epithelioma of the cervix. Analysing his last 200 consecutive cases of abdominal hysterectomy for fibroids, he had found that 26 patients were under the age of 40, and in none of these was the fibroid complicated with malignant changes. Among the remaining 174 there were 8 cases of malignancy. Of these, 3 were associated with adenocarcinoma of the body, 2 with epithelioma of the cervix, and 3 were sarcomatous. The combination of squamous cancer of the cervix with fibroids must be regarded as an accidental occurrence, but there seemed to be some etiological association between adenocarcinoma of the body of the uterus and fibroids. His view was that when fibroids were found in a woman over the age of 40 the uterus should be removed on account of the increased tendency to malignant complications after that age.

## Rebuelus.

### RADIOLOGY.

THREE out of four volumes of the work entitled *The Theory and Practice of Radiology*,<sup>1</sup> by Dr. BERNARD J. LEGGETT, have been published. These are, respectively, on "Electrical theory applied to radiology," "The physics and measurement of  $\alpha$ -radiation," and "X-ray apparatus and technology." The fourth volume, which is in course of preparation, will deal with the "Diagnostic and therapeutic applications of  $\alpha$ -radiation." The three volumes under review are large books, profusely illustrated; volumes i and ii have each from 240 to 300 pages, and the third is even larger, for it runs to 550 pages. It need scarcely be said that between them they cover very completely the whole of the subjects indicated by their titles, and we may add that they do this in a very systematic and detailed manner. The student who is preparing himself for one or the other of the diplomas in radiology should most certainly find in them the answers to all the questions he is likely to be asked either in the papers or in the oral part of the examination, and incidentally it would appear that they contain a great deal which he certainly would not have asked. The author has introduced at the end of most of the subjects a series of questions based largely on those set for D.M.R.E. examinations; they are suggested as "exercises" upon the chapter or chapters dealing with the particular subject. No doubt the correct answers could, in most cases at any rate, be dug out from the text, but we venture to suggest that as the questions are set it would have added greatly to their value, if not to that of the volume, if the author had seen fit to add, perhaps in an appendix, his conception of how these questions should be answered.

To take the volumes separately. Number one has six chapters, which discuss separately the dielectric circuit, the electric circuit, the magnetic circuit, varying currents, electro-magnetic machinery, and the electron theory. Numerous illustrations help to elucidate the text, but a good deal of the mathematics included therein makes it somewhat hard reading for the ordinary medical man. We do not, however, mean this remark to be taken in any sense as adverse criticism: the author clearly indicates that, though primarily written from the point of view of radiology, the work was not written for the purposes of any particular examination.

The second volume is concerned with the physics and measurement of  $\alpha$ -radiation, and deals, among other things, with light and heat, the origin and properties of  $\alpha$ -radiation, the measurement of both quality and intensity, and the dangers of radiology. In two appendices the author adds the various recommendations upon protection and those relating to dosage. He rather adversely criticizes the English recommendations on protection, chiefly from the point of view of their effect on manufacturers' difficulties. It is of interest to note that up to the present the regulations in Russia are the only official ones enforceable by law. Some fifty pages are allotted to a chapter on the dangers of radiology, not only the risks from the rays themselves, but also the various electrical and other dangers. This is a valuable chapter, full of useful information and references to literature. Volume iii is very large, and savours overmuch of the instrument maker's catalogue; at the same time this perhaps enhances its value as a reference book in which information on any point of instrumentation can easily be turned up and the more readily understood by means of the pictures. Nothing appears to have been omitted. A chapter is devoted to the radiological chapter is that on the radiological as it is with plans of departments, but Useful information on this subject has often in the past been difficult to obtain, and in this chapter, again profusely illustrated, a distinct want has been practically dealt with. In another part the different kinds of  $\alpha$ -ray

tubes are described and compared; whilst the detailed account and description of high-tension transformers is of great value.

It is not possible in a review of this kind to enter into any further minute detail. The three volumes are excellently got up, printed in good legible type, and the illustrations leave nothing to be desired. We can congratulate the author upon a fine piece of work, invaluable for reference and a mine of information for those in search of expert knowledge.

### BLOOD PRESSURE.

THE fourth edition of *Blood-Pressure: Its Clinical Applications*,<sup>2</sup> originally written by Professor G. W. NORRIS, appears with the collaboration of Dr. H. C. BAZETT, professor of physiology in the University of Pennsylvania, and Dr. T. M. McMILLAN, cardiologist to the Philadelphia General Hospital. The spirit of team-work is further shown by the inclusion of four chapters by authorities on blood pressure in nervous diseases (Dr. F. G. Grant), surgery (Dr. G. P. Müller), obstetrics (Dr. N. W. Vaux), and ophthalmology (Dr. H. W. Searlett). The chapters on physiology are now. Professor Bazett, after stating Poiseuille's law, lays stress on the importance of recognizing that a rise in blood pressure does not necessarily imply any increase in the peripheral resistance, and that a normal mean blood pressure, which is obtained by adding one-third of the pulse pressure to the diastolic, is not a definite indication of a normal circulation, for a normal pressure level can be maintained by abnormal adjustments of the circulation rate and the peripheral circulation; thus the systolic and diastolic pressures are often practically normal when dyspnoea, oedema, and cyanosis are present. Whereas an abnormally high or low blood pressure shows that the circulatory rate or the periphery resistance is disordered, a normal blood pressure does not prove that these factors are normal. The subject of the capillary and venous blood pressures is duly summarized, and diurnal and postural variations are described under physiological considerations, and again in the following chapter.

The section on instrumental estimation of blood pressure is copiously illustrated by useful figures and diagrams, and attention is called to the occurrence, when the auscultatory method is used, of unexplained periods of silence, so that palpation at the wrist may give a higher systolic pressure than by the auditory method; this "silent gap" is more frequent in repeated estimations than in the first of a series, and in some circumstances, but not in all, its presence may be due to venous engorgement. Silent gaps have attracted very little attention in this country, except from P. C. Gibson. After discussion of the variations of blood pressure that may be regarded as physiological, the functional efficiency of the circulation as estimated by blood pressure and allied tests is fully considered.

The important subject of pathological high blood pressure, meaning thereby pressures above 160 mm. Hg systolic and 100 diastolic, receives full and satisfactory treatment, and much useful and some curious information is given, such as Quinlan's view that high blood pressure is commoner in left-handed than in right-handed persons. The directions as to treatment are thoroughly sensible, and this well-written treatise well maintains its reputation as a useful practical guide and source of reference.

Under the title *L'hypertension artérielle solitaire*<sup>3</sup> Dr. J. PELLISSIER discusses the much debated subject of high blood pressure without any discoverable morbid lesion such as nephritis. This, in fact, is the essential hypertension of many authors, especially Americans, but the adjective "essential" is adversely criticized by the author as being, like "idiopathic," merely a cloak for ignorance. In this critical essay, which contains the details of sixty cases studied clinically, and a bibliography of 249 items, including

<sup>1</sup> *The Theory and Practice of Radiology*. By Bernard J. Leggett. M.R.C.S., L.R.C.P., A.M.I.E. A Treatise in four volumes. London: Chapman and Hall, Ltd., 1928. (Roy. 8vo, Vol. I, pp. xii + 238; 188 figures; 18s. net. Vol. II, pp. xi + 308, 203 figures; 25s. net. Vol. III, pp. xi + 550; 534 figures; 42s. net.)

<sup>2</sup> *Blood-Pressure: Its Clinical Applications*. By George William Norris, A.B., M.D., Henry Cuthbert Bazett, B.Sc., B.Ch., Oxon., and Thomas M. McMillan, A.B., M.D. Fourth edition, thoroughly revised. London: Henry Kimpton, 1928. (Med. 8vo, pp. viii + 387; 1 coloured plate, 47 figures. 21s. net.)

<sup>3</sup> *L'hypertension artérielle solitaire*. Par L. Pellissier. Paris: Masson et Cie, 1927. (Med. 8vo, pp. 272. 30 fr. sans majoration.)

a fair sprinkling of English papers, it is rather surprising to find that there is no reference to hyperpiesia or to Sir Clifford Allbutt. The conception that there is a form of pure primitive high blood pressure without any causal renal lesion is ascribed to Vaguez in 1903, who considered that the excessive activity of the adrenals was the responsible factor. After some discussion in the light of more recent knowledge, Dr. Pellissier, who admits that he has never found any macroscopic or microscopic evidence of changes in the adrenals of his cases, concludes that the rise of arterial blood pressure is due to excessive adrenalinaemia, which, however, is only the means, and not the primary factor. The underlying cause is a disorder of humoral metabolism, which stimulates the adrenals, breaks down the physico-chemical balance, and irritates the sympathetic system.

### A TEXTBOOK OF BIOCHEMISTRY.

PROFESSOR A. T. CAMERON'S *Textbook of Biochemistry*<sup>1</sup> is certainly not a ponderous volume, yet it contains a remarkably complete survey of a very wide field. The book is in substance the written version of courses of lectures delivered to students of science and of medicine. Thus it assumes in the reader no previous knowledge of biochemistry, and, as each successive topic is dealt with, the fundamentals are explained before the details are described.

The busy medical student will find in this book a concise account of the facts with which he is expected to become familiar, while, for the benefit of those who wish to explore the subject further, more detailed accounts of topics of general interest are appended. There is, for instance, a very interesting section on comparative digestion, which includes descriptions of the digestive processes of plants, protozoa, invertebrates, and vertebrates, and a chapter on biochemical processes in industry, describing some ingenious practical applications of the subject. It should also be noted that sensible and scientific accounts of diet and vitamin requirements are given, which will provide the student with a sound basis for studying dietetics. Indeed, by dint of the skill with which he has condensed an unwieldy mass of material into small compass, at the same time omitting nothing essential, Professor Cameron has created a quite exceptionally readable textbook.

The author himself puts forward in his preface the plea that it is necessary, in order to avoid confusing the elementary student, to adopt a somewhat dogmatic attitude when dealing with controversial points. This is doubtless true, yet the one fault we have to find with the book is that it contains one or two statements which are definitely not in agreement with the facts as at present known. For example, while the author's unquestioning belief in the existence of the enzyme urease in crystalline form may surprise the cautious, it is quite possibly well founded; but his conclusion that the ammonia present in the urine is formed by the kidney from urea has a large weight of evidence against it. Similarly the statement that pepsin does not attack the CO-NH links in proteins is definitely contradicted by the results of recent researches on peptic digestion. These are, however, matters of detail, and will certainly not prevent this *Textbook of Biochemistry* from attaining the popularity with students and teachers which it undoubtedly deserves.

### PEDIATRICS.

NEARLY seven years have passed since Professor J. P. CROZER GRIFFITH first published his textbook in two volumes on *The Diseases of Infants and Children*,<sup>2</sup> and for the second edition now published he has had the assistance of Dr. A. GRAEME MITCHELL. The preface says that every part of the book has been subjected to a thorough review, and it is obvious from the references to recent literature

profusely appearing throughout the work that this edition has been completely revised. The result is an authoritative textbook, well illustrated, carefully documented, and, above all, presenting a very well balanced account of the vast subject. An excellent feature is the inclusion of such subjects in surgery and the special branches with which physicians treating the diseases of children should be more or less familiar.

It may be complained that the two large volumes which result contain too much for the general practitioner, but as a work of reference it is remarkably practical in its detail on such matters as diagnosis and treatment. In this respect there are still some small matters calling for criticism. The author states that he is embodying in the book largely the results of his own experiences, but it is scarcely fair to say (p. 647, vol. i) that tuberculous mediastinal glands present "few if any clinical manifestations," nor is it in accord with modern teaching to include coeliac disease vaguely along with other forms of "chronic intestinal indigestion in older children" (p. 142, vol. ii). The treatment of scurvy (p. 718, vol. i) is rather brief, no mention being made of such methods as the use of deacidified lemon juice. The inclusion of such conditions as "athrepsia" and "malnutrition" in the first volume—a long way from the digestive disorders and feeding difficulties—does not help in a proper conception of nutritional disorders in infants, and, if these terms are to be used at all, they do not justify inclusion of the disorders in a section containing such other diseases as rickets and rheumatism, for example.

Such criticisms almost exhaust the faults to be found in more than eighteen hundred pages; for the rest the work demands high praise. The section on the acute infectious fevers is especially good, and there is much to be learnt from the description of such disorders from the point of view of a pediatrician rather than of the specialist confining his activities to the fever hospitals, as in this country. Rickets is well described, and a well-documented brief summary of its etiology is very good. The section on diseases of the respiratory system begins with a useful chapter on "cough," and the treatment of the common cold in children is well set out. The specialist will find much that is stimulating to thought in these two volumes, and the general practitioner will not go to them in vain for help in the solution of his most trivial problems.

### POST-MORTEM TECHNIQUE.

THE new edition of Dr. SHENNAN'S book on *post-mortem examinations*,<sup>3</sup> which has been long overdue, shows evidences of considerable revision. While the original plan remains the same, additions have been made in the descriptions of the lesions with the object of making the work to some extent a textbook of special pathology as well as a guide to *post-mortem* technique. Among the sections which have been extended in this direction may be mentioned those on diseases of the blood vessels, on pneumonia, on the thymus and thyroid, on jaundice, on the splenomegalies, on nephritis, and on diseases of the nervous system. Further, additional measurements have been furnished of the embryo and of children from birth onwards, and a chapter has been added on medico-legal *post-mortems*, on *post-mortems* on stillborn infants, and on cases of death under anaesthesia. Much of the subject-matter of the old edition has been rewritten and the remainder recast, so that, as the author states, the work is practically a new book. It is the outcome of Dr. Shennan's long personal experience in *post-mortem* work, and therefore contains first-hand information on the subject and technical recommendations that have stood the test of time. With regard to the arrangement of the subject-matter, the *post-mortem* room and its equipment is first described, with general rules as to the conduct of the necropsy and the restoration of the body after its performance. Then follow the external examination of the body and the opening of the body cavities, with the order of removal and methods of examination of the

<sup>1</sup> *A Textbook of Biochemistry*. By A. T. Cameron, D.Sc.Ed., F.I.C., F.R.S.C. With a foreword by Professor Swale Vincent, LL.D., M.D., D.Sc., F.R.S.E., F.R.S.C. London: J. and A. Churchill, 1928. (5½ x 8½), pp. x + 462; 12 figures. 15s.

<sup>2</sup> *The Diseases of Infants and Children*. By J. P. Crozer Griffith, M.D., Ph.D., and A. Graeme Mitchell, M.D. Second edition, reset. Philadelphia and London: W. B. Saunders Company, 1927. (Roy. 8vo, Vol. I, pp. xiii + 783 + 65; 233 figures. Vol. II, pp. viii + 927 + 65; 228 figures; 20 coloured plates in the two volumes. 90s. net the two volumes.)

<sup>3</sup> *Post Mortems and Morbid Anatomy*. By Theodore Shennan, M.D., F.R.C.S.Ed. Second edition. London: The Scientific Press (Faber and Gwyer, Ltd), 1927. (Demy 8vo, pp. viii + 664; 213 figures. 25s. net.)

viscera. A valuable chapter on certain special cases deals with necropsies following death from poisoning, the account of which is very full, and other cases of medico-legal importance. In an appendix useful information is given on methods of preserving specimens for the museum and on simple methods of preparing microscopical sections and staining bacteria. The section devoted to the performance of a necropsy in private houses furnishes hints which, if followed, will render that operation less unpleasant to the operator and the inmates than is sometimes the case.

#### APPENDICITIS.

THE latest addition to the Surgical Monograph Series is *Appendicitis*,<sup>1</sup> by H. A. ROYSTER. This monograph resolves itself into a collection of many and varied facts and theories concerning appendicitis, which the author has succeeded in correlating and criticizing in such a way as to produce a very clear and practical description of the etiology, pathology, diagnosis, treatment, and complications of inflammation of the appendix.

Many interesting observations are made on the etiology of the disease, especially with regard to the part played by diet, intestinal worms, and foreign bodies. Pathology is discussed in relation with etiology. The chapter on diagnosis contains many useful suggestions, and the value of x-ray diagnosis in chronic appendicitis is fully discussed. A chapter is devoted to appendicitis in children, and this gives a particularly clear description of the difficulties and dangers of the disease in these circumstances. The prognosis of appendicitis is careful and fully considered, and special attention is directed to the gradually increasing mortality rate at the present time in the United States. Dr. Royster says that the one way of lowering the death rate in appendicitis is to operate at the first onset of symptoms of inflammation of the organ. "Far better results are obtained by the mediocre surgeon in early cases than by the more capable operator in late cases made dangerous by complications." The full and lucid review of treatment of the disease in every phase should prove useful to the surgeon as well as to the general practitioner. Complications, their prevention, and treatment are well described, and also special points in the post-operative care.

At the end of each chapter a long list of references is given which will be useful to those requiring more detailed knowledge of any branch of the subject.

#### THE MAKING OF A MAN.

IN *The Struggles of Male Adolescence*<sup>2</sup> Dr. C. STANFORD READ provides a thoughtful account of the influences which underlie the confused psychological development of this stage in life. He approaches their consideration from the Freudian standpoint, but avoids what he stigmatizes as "freakish interpretation of ill-digested theories," and retains throughout a clear practical outlook. Opening with an exposition of the various conflicting psychological trends, he emphasizes the danger of neglecting these at the time when they can be most conveniently dealt with. A vivid picture is given of these warring forces as being a necessary part of normal growth into manhood; and the development of various reactions to them, such as repression, compensation, displacement, and identification, is traced. The second part of the book is concerned with the possible results of this conflict and the paths which lead to health. The reader can hardly fail to be reminded of Kipling's story of the ship that found herself, and some will recall the deep insight into human character revealed in ancient Hindu literature, which describes symbolically the yoking and control of the diverse elements in the personality. On this "finding of oneself" depends very largely the happiness and usefulness of human life, and Dr. Read has made a very valuable contribution not only to individual, but also to national welfare. There

are few short cuts to success in the task of character training or in therapeutical psychology, but careful perusal of this book by medical practitioners, teachers, and parents would make the way easier for many of them. The author has told a difficult tale in simple language. Any criticism of details would be out of place in view of the value of his work as a whole, regarded either as a textbook of one branch of preventive medicine or as a contribution to the science of education.

#### NOTES ON BOOKS.

THE plan adopted by Dr. C. D. AARON in his textbook on *Diseases of the Digestive Organs*<sup>3</sup> is to follow the path of the digestive tract, beginning with diseases of the stomach, liver, gall-bladder, bile ducts, pancreas, small intestine, vermiform appendix, caecum, colon, rectum, and anus. Although the diseases of these different organs are considered chiefly from the medical point of view, the author includes descriptions of the simple pathology and diagnosis of diseases which come within the province of the surgeon—as, for instance, tumours—but does not attempt any complete account of surgical treatment. General medical and dietetic treatment are given special prominence, and there are chapters on massage and electrical treatment and mineral waters. The book is well illustrated and indexed, and will be found a useful work for reference.

*Gynaecology for Nurses*<sup>4</sup> is the title of the latest publication from the pen of Dr. CROSSEX of Washington, but we would suggest that "An atlas of gynaecology" would more aptly describe the book. In some 230 pages there are 365 illustrations, all of which are well produced. Many are unnecessary, for surely microscopical pathology is beyond the province of a nurse. In the text there appears to be a lack of proportion in the space allotted to the various subjects, which are, however, on the whole well described. For those engaged entirely in the operating theatre of a gynaecological ward the book may serve a useful purpose; to the many others in the nursing profession it will appear spectacular, but of small value.

The thirty-sixth edition of the Charity Organisation Society's *Annual Register and Digest*<sup>5</sup> of charities in the United Kingdom has now appeared. The useful classification of previous editions is retained, so that with the aid of an excellent index it is easy to trace institutions which give relief in the various forms of affliction, sickness, and permanent or temporary distress. The usual review of the previous year deals lucidly with the finances of institutions situated in or available for the metropolis. This edition will maintain the high reputation won by previous issues; it is an indispensable book of reference.

<sup>1</sup> *Diseases of the Digestive Organs, with Special Reference to their Diagnosis and Treatment*. By Charles D. Aaron, Sc.D., M.D., F.A.C.P. Fourth edition, thoroughly revised. Philadelphia: Lea and Febiger. 1927. (Med. 8vo, pp. 927, 174 figures, 25 plates, 11 dollars.)  
<sup>2</sup> *Gynaecology for Nurses*. By Harry Sturgeon Crossen, M.D., F.A.C.S. London: H. Kimpton. 1928. (Sup. roy. 8vo, pp. 281, 365 figures, 12s. net.)  
<sup>3</sup> *The Annual Charities Register and Digest*. Thirty-sixth edition. London: Longmans, Green and Co., Ltd., and the Charity Organisation Society. 1928. (Demy 8vo, pp. xx + 553, 8s. 6d. net.)

#### PREPARATIONS AND APPLIANCES.

##### "VAPOROLE" EPHEDRINE.

THE Chinese drug ephedrine, which produces an action closely resembling that of adrenaline, has proved of great value in the treatment of asthma. Messrs. Burroughs Wellcome and Co. have issued a "vaporole" preparation of ephedrine for application to the pharynx and nose by means of an atomizer. The spray compound consists of ephedrine 1 per cent., menthol, camphor, and oil of thyme of each 2 per cent. in a base of "paroleine" (a high quality liquid paraffin). Such a spray enables ephedrine to be efficiently applied locally in hay fever and congested conditions of the pharynx and nasal mucosa. It is stated that clinical trials of this new method are exceedingly satisfactory, and promise to provide a very effective weapon for the symptomatic relief of hay fever and of engorged and catarrhal conditions of the nasopharynx.

##### LIVER EXTRACT B.D.H.

WE have received from the British Drug Houses, Ltd., a sample of liver extract. This is a powder prepared by a process which has been tested clinically and found efficient by the Medical Research Council. The contents of one tube correspond to half a pound of fresh liver, and this quantity has been found to be the most suitable daily dose in pernicious anaemia. The remarkable value of liver treatment in pernicious anaemia is now universally recognized, and the liver extracts possess advantages over whole liver in respect of palatability and simplicity of preparation.

<sup>1</sup> *Appendicitis*. By Hubert Ashley Royster, A.B., M.D. Surgical Monographs, under the editorial supervision of Dean Lewis, A.B., M.D., Eugene H. Pool, A.B., M.D., and Arthur W. Eling, A.B., M.D. New York and London: D. Appleton and Co. (Sup. roy. 8vo, pp. xii + 370, 56 figures, 2 plates, 21s. net.)  
<sup>2</sup> *The Struggles of Male Adolescence*. By C. Stanford Read, M.D. London: George Allen and Unwin, Ltd. 1928. (Post 8vo, pp. 248, 7s. 6d. net.)

# SOME COMMENTS ON THE CASE OF TYNDALL v. ALCOCK:

WITH REMARKS AS TO THE ORIGIN OF ISCHAEMIC CONTRACTURE.

BY

ERNEST W. HEY GROVES, M.S., F.R.C.S.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF BRISTOL; SURGEON TO THE GENERAL HOSPITAL, BRISTOL.

PROBABLY the majority of medical men who heard or read the account of this case, reported briefly in the *British Medical Journal* of December 10th, 1927 (p. 1121), and March 24th, 1928 (p. 528), were greatly shocked at its result. There can be no doubt that it throws an added light on the dangers which beset the practitioner in the treatment of a fracture.

Let me first briefly relate the accepted facts of the case and the trial.

In July, 1926, a girl, Phyllis Tyndall, aged 8 years, fell from a donkey and hurt her left elbow. Mrs. Tyndall, the patient's mother, did not take her child to the nearest doctor for first aid or bandaging, but decided to apply to Dr. Alcock,

FIG. 1.—Before reduction.

surgeon to the Gloucester Royal Infirmary. Accordingly, with the assistance of a neighbour, the child was taken in a motor car to Gloucester, a distance of ten miles, without any splint or sling, the injured arm being merely held in a more or less extended position of the elbow-joint. Dr. Alcock, being apprised by telephone, was waiting to receive the patient, and actually first saw her in the motor car. He recognized the serious character of the injury, and therefore did not have the child out of the car, but himself got into it and was driven to the consulting rooms of Dr. Goss, the leading radiologist in Gloucester. In Dr. Goss's rooms the child was anaesthetized and x-rayed. This showed a typical supracondylar fracture of the humerus, with great backward and upward displacement of the distal fragment, and the shaft of the broken bone so near the skin surface that it must have been pushed forwards through the muscles and other soft tissues in front of the elbow-joint (Fig. 1). Dr. Alcock then made traction upon the forearm, and gradually flexed it at the elbow, bringing the hand up till the fingers touched the shoulder of the injured limb. He felt the displaced lower end of the humerus move forward into place, and being satisfied as to the reduction of the displacement, he fixed the arm up in full flexion by passing adhesive plaster round the doubled-up limb. There was no pad in the flexure of the elbow, nor any bandage encircling any part of the arm or forearm. A bandage was placed over the flexed arm, and at this stage a further examination was made by the x-rays, with the screen, and Dr. Goss told Dr. Alcock that the reduction had been satisfactory and the position good.

In order to obtain a record of this position a plate was taken. The child was still unconscious, lying on the x-ray couch, the tube being below. In order to get a lateral view of the elbow

the arm was rotated outwards so that the hand lay on the same level as the back, but on the outer side of the shoulder. The resulting x-ray film (Fig. 2) was not developed until the next day, and it is not quite clear when Dr. Alcock saw this, as his opinion that satisfactory reduction of the displacement had been effected depended on his own palpation of the limb at the time of the manipulation and upon Dr. Goss's opinion of the screen examination. However, as it so happened, the trial largely turned upon the interpretation of this x-ray film.

The x-ray picture having been taken, the arm was replaced with the hand in front of the shoulder and a bandage passed round the body and left arm; thus there were three sets of bands round the limb—first, adhesive plaster; second, a bandage, these two going round the doubled-up arm; and a third bandage surrounding the arm and body.

Dr. Alcock then took the child in a motor car to a nursing home himself, and gave instructions about her care. She remained in the home for fifteen days, and Dr. Alcock saw her daily during this period. From the first few days and onwards Mrs. Tyndall, the patient's mother, was constantly asking that the child might be taken home, but Dr. Alcock absolutely refused to hear of this. Within a day or two of the accident it became apparent that the circulation of the hand was impaired, and the extreme position of flexion was relieved, the arm being brought down first by a few degrees and then to nearly a right angle.

FIG. 2.—After reduction, arm in acute flexion.

It was not clear at what precise moment Dr. Alcock recognized the existence of ischaemic paralysis, and he stated quite frankly that he had in a large experience never seen such a condition before. It was, however, pretty clear that he did recognize the gravity of the condition before the child left the home, as he told this to one of the relatives. For about two months more the child attended the Gloucester Infirmary as an out-patient under Dr. Alcock's care, but as the authorities of that institution did not consider she was a suitable patient for a charitable institution she was transferred to the Children's Hospital, Bristol. X-ray photographs at that institution showed posterior displacement of the lower end of the humerus, which had become attached to the shaft by a new periosteal bridge, the original shaft of the humerus projecting forwards above and in front of the elbow. An operation was performed, and the projecting portion of the humerus was removed, but this did not materially improve the elbow, which was almost fixed at a right angle. The final condition of the arm showed a well-marked ischaemic contracture of the forearm flexors and a stiff elbow. Dr. Alcock, after a trial lasting four days, was found guilty of "negligence," and was ordered to pay £2,000 damages to the plaintiff, Phyllis Tyndall, and £150 to Mrs. Tyndall, to reimburse the latter for expenses incurred in the treatment.

Having now given the main facts of the case, I should like to make certain comments on its medico-legal bearings. The first and most glaring thing is the interpretation which was put on the term "negligence." I venture to say there never was, and never will be, a fracture case which was treated with greater care and solicitude than that of Phyllis Tyndall by Dr. Alcock. He met her in the

motor car; he took her to an x-ray specialist; he anaesthetized her; he used the x-rays before and after treatment; he treated her by the universally approved method; he was assured by an experienced radiologist that the position was satisfactory; he took the patient himself to a nursing home, and gave her unremitting care first at the home and then as a hospital out-patient. And yet this is consistent with negligence!

The second striking fact is the way in which a fracture case and the reading of an x-ray film lend themselves to misinterpretation by a jury. Counsel for the plaintiff made a great point of this being "a perfectly simple fracture." In the technical sense that it was a closed and not an open fracture this was quite true, but if by this it was meant that the case was a simple one in the ordinary sense of the word, and presented no difficulty, I most strongly disagree. There was not only fracture, but great displacement; the child had been jolted over a rough road in a motor car without the protection of any splint or sling; the shaft of the humerus was almost projecting through the skin, so that it must have torn through the overlying muscles; and yet this was a "perfectly simple fracture"! And again, take the phrase "setting a fracture." The common idea is that setting a fracture consists in perfect locking together of the broken surfaces, whereas it is common knowledge that this is very seldom done apart from open operation. That displacement can be reduced or even over-reduced, leaving the fractured surfaces in a favourable position for union by callus, though not actually touching one another, is an idea not acceptable to the lay mind.

Great controversy took place on the interpretation of the x-ray film taken after manipulation. Was it an antero-posterior or a lateral view? The plaintiff's experts held that it was an antero-posterior view, in spite of Dr. Goss's plain description of how it was taken. They said that the shape of the bones showed that they were viewed in an antero-posterior direction. In giving this opinion the fact was ignored that the arm was rotated outwards in order to get the picture, and also that this picture did not represent the bones as they lay when the arm was placed in front of the chest.

If the picture is an antero-posterior view, then it shows some lateral displacement; if it is a lateral view, then it shows that the displacement has been over-reduced and that the lower fragment of the humerus has been brought forward to lie rather in front of the shaft. But in any case, what has this to do with ischaemic paralysis or the stiff elbow? Apparently it was enough to convince the jury that the bones had not been "set" for them to conclude that the paralysis was caused by this faulty setting. The plaintiff's case was that there was lateral displacement of the lower end of the humerus upon the shaft, but not one word of explanation was given as to how this lateral displacement could constrict the artery or cause ischaemia. The idea of a blood effusion round the fracture first pressing upon the veins and then bringing the circulation to a standstill was dismissed as hypothetical. No effusion could be seen in the x-ray pictures, but the "misset" bones were there, and that was enough.

The next point upon which I should like to comment was the interpretation put upon Dr. Alcock's conduct after the first treatment and upon the indefiniteness of his evidence.

Great stress was laid upon discrepancies of various witnesses about the releasing of bandages. Mrs. Tyndall declared that for fourteen days the bandages were never released; but evidence was given that she had never seen the arm undone, and she only judged by the fact that she always saw it surrounded by the body bandage.

Then it was impossible to be certain on which day the flexion of the arm was released. But surely after the lapse of eighteen months this is quite natural. In the same way Dr. Alcock could not be clear when or how he first recognized the existence of ischaemic paralysis. This may seem strange to a layman; but surely any man of experience knows that the onset of failing circulation and the signs of congestion may be, and indeed often are, insidious, and that if a limb is covered with a bandage, easily overlooked. Dr. Alcock certainly realized before a week had passed that

he had charge of a bad case. He could quite easily at any time within the first few days have got out of all his difficulties by allowing the mother to take the child home, as he alleged she repeatedly asked. Instead of this, he persisted in keeping the child under his care. But instead of recognizing this as the action of a careful and conscientious man, it was represented to the jury as being the conduct of one who knew he had made a fatal blunder and wished to hide it.

The nature of the damage to the arm was very difficult to explain fairly. It is true that the muscles or muscle fibres affected by ischaemic paralysis are permanently lost, and this was represented as though the whole forearm was permanently and totally paralysed. In reality it is only certain groups of muscles which are affected, and usually some fibres of even these escape, so that, as Sir Robert Jones has shown, ischaemic contracture is capable of great amelioration by patient treatment, and the hand becomes ultimately quite useful in a limited degree. Similarly the fibrous ankylosis of the elbow is a condition susceptible of improvement. But in this case it was suggested that the left arm was permanently useless, and that the child, who was represented as a potential musical genius, had had her career wrecked.

But there is another question of great importance suggested by this case, quite apart from the manifest absurdity of saying that a want of alignment of the bones caused paralysis of the arm—and that is, What was the real cause of the ischaemia, and could this have been avoided? It is a matter of common agreement that the prime cause of ischaemic contracture is a damage to the blood vessels and soft parts. This may have been caused at the time of the accident, and was probably aggravated by the want of proper "first aid." The condition of a child with a broken elbow-joint surrounded by swelling and effusion is one which often has to be considered and the correct line of treatment determined. On this very point there is not enough emphasis laid down in textbooks upon the importance of watching the circulation rather than the fracture; and in particular it is not usually recognized that acute flexion of the elbow always has a constricting effect upon the blood vessels. In all individuals in whom I have tried the experiment, including myself, forced flexion of the normal elbow-joint can readily be brought to a point where the radial pulse ceases. And to this observation another may be added. A case is taken in which some operation in the neighbourhood of the elbow-joint is to be performed. It is noted what degree of forced flexion is required to cause cessation of the radial pulse. Then after the arm has been relaxed, about one ounce of saline solution is injected under the skin and deep fascia in front of the elbow. The arm is then again flexed, and it will be noted that the radial pulse disappears with a much less extreme flexion than before. This shows that the mere presence of effusion round the joint, quite apart from actual injury to the blood vessels, makes flexion of the elbow liable to obstruct the circulation; therefore it should be clearly understood that it is always a most dangerous thing to flex a swollen elbow-joint, and if this is done a most careful watch should be kept on the radial pulse, both at the time of manipulation and for some days afterwards.

When a case of fracture of the lower end of the humerus is presented for treatment some hours after the accident, presenting much swelling, it is far better to be content to leave the limb alone, simply supported upon a pillow, until the effusion has subsided. It is quite true that this delay generally means that manipulative reduction of the fracture will be impossible, and in these circumstances open reduction, which is quite a simple matter, is indicated. Through an external or posterior incision the blood clot is evacuated, the separated fragment is replaced, and then a moderate degree of flexion will be quite enough to retain it in position without any actual suturing of the bone itself.

It is perhaps unnecessary to add that if ischaemic paralysis has already developed, then no reposition of the bone, even if done within a few days of the accident, will have any effect in relieving it—another proof, if such were needed, of the absurdity of suggesting that ischaemia could be in any way due to a want of alignment of the bones.

## PHYSIOLOGY OF THE CEREBRAL HEMISPHERES.

## PROFESSOR PAVLOV'S CROONIAN LECTURE.

THE Croonian Lecture on certain problems in the physiology of the cerebral hemispheres was delivered before the Royal Society by Professor I. P. Pavlov, For. Mem. R.S., on Thursday, May 10th. The following is an abstract.

The function of the nervous system is to maintain dynamic equilibrium within the organism, and between the organism and its environment. In the latter case the equilibrium is, in the higher animals, extremely complex, and is achieved mainly by means of the hemispheres. These continuously analyse and synthesize events occurring in the environment, and in correspondence with its changes establish temporary connexions between events, whether simple or complex, and various activities of the organism, in particular those of the skeleto-muscular system, which is preponderantly concerned in reacting to environmental changes, and is likewise itself highly differential and integrative in its response.

At present the physiology of the hemispheres exists only in outline—as a framework consisting of only a limited number of known factors, such as excitation and inhibition, their two-directional movement in the form of irradiation and concentration, and their mutual induction. The working out of the innumerable details of their intimate mechanism is a colossal problem of the future. At present in this respect we do but collect fragmentary observations, a small part of which, comprising the latest investigations carried out by the author and his co-workers (subsequent to the publication of the author's book *Conditioned Reflexes*), are given here in summarized form.

## I.

The development of new temporary connexions between external agencies and definite reactions of the organism (development of conditional reflexes) depends on the coincidence in time of the action of these agencies upon the receptor mechanisms of the organism with the various activities of the organism evoked either by external stimuli effective since birth, or by external stimuli which have become established as such after birth, or finally by changes in the internal condition of the organism (automatic stimuli). Under these conditions the formation of the connexion is a physiological law.

In order to become a firmly established, powerful, conditioned stimulus the external stimulus must begin to act slightly before the particular activity of the organism, and may even cease a few seconds before the beginning of the activity. If, on the other hand, the given activity constantly begins before the stimulus, either no connexion is established or, if any is established, it is weak and survives only for a short time, and the specialized excitatory effect of the stimulus is invariably replaced by general inhibition. The biological significance of this fact is not yet clear. Where the stimulus begins to act before the given activity of the organism, and continues during that activity, the reflex tends to increase in strength and stability.

The mechanism underlying these phenomena cannot be expressed in terms of the general properties of the cortical tissue without further investigation.

## II.

The analysing activity of the nervous system is founded in the first instance on the peripheral receptor organs, which constitute not only a receptive mechanism, but also an analysing apparatus of the organism. To the peripheral points of the analyser separate points correspond in the cortex (the primary and simplest cortical mosaic). A good proof of this is that by applying definite external stimuli belonging to the same analyser—as, for example, different auditory stimuli—it is possible to produce various disturbances or fatigue at different strictly localized cortical points. In this manner a very delicate method is opened up for investigating the construction of the cortical parts of the analysers, and it is possible to distinguish special areas in the cortex relating to the different analysers, such as the visual and auditory, from certain other cortical elements of those analysers, which are dispersed probably over the whole mass of the cortex of the hemispheres. Not only are these dispersed elements incapable of performing

any higher synthesis and analysis, but they have a very low degree of vitality, as evidenced by the rapidity of their transition into an inhibitory state under the influence of external stimuli.

## III.

The conditions determining the characteristics and the magnitude of the excitatory and the inhibitory effects of conditional stimuli are bewilderingly complex, and are only gradually being registered and classified.

It is obvious that the magnitude of the positive effect is directly related to the amount of energy applied to the receptor organ. The phenomenon of summation of weak stimuli comes out clearly. The limit of normal excitability and the optimum strength of stimulation are also definite. In the case of very strong stimuli and of the summation of medium stimuli the excitatory process rapidly changes into an inhibitory one. Of course, the strength of stimulus is a relative quantity, varying greatly with individual differences of nervous system.

Since most probably the points between which the new connexions are established are in the cortex, it follows that the variations in the effect of conditioned stimuli will be dependent on the mutual relation between the different cortical points corresponding with the different conditioned stimuli, and also between the different points of those areas of the hemispheres which are affected by the unconditioned stimulus. For instance, the conditioned stimuli based on food and acid respectively become connected with the chemical analyser of the hemispheres, and therefore, if in the experiments both sets of conditioned stimuli are used, their effect will be determined not only by the interrelation of the points corresponding to the stimuli, but also by the relation existing between the alimentary and "acid" points of the chemical analyser.

## IV.

The accumulation of observations upon the normal and pathological activities of the hemispheres gives grounds for distinguishing various types of nervous system. There is the excitable type, which always displays partial or complete failure when confronted by difficult relations between the excitatory and inhibitory processes, and which, if the experiments are continued, ends by developing an abnormal and extremely protracted weakening of the inhibitory activity, attended by an exaggerated general excitation. At the other extreme stands the inhibitable type, which very easily becomes subjected to inhibition by stimuli either unusual or slightly stronger than usual, and which, when confronted by comparatively difficult relations between the excitatory and inhibitory processes, passes into a state of complete inhibition for prolonged periods of time.

In between can be placed the well-balanced type which, successfully and without any signs of abnormality, establishes in all cases a balance between the opposed nervous processes. This type comprises two varieties of animal, differing greatly from one another in external appearance—the stolid animal, always quiet, and the animal which is lively under ordinary conditions, but becomes drowsy with surprising rapidity under monotonous conditions. The latter variety has some difficulty in obtaining a balance between the two processes. This grouping of the types of nervous system corresponds closely to the ancient classification of temperaments: the excitable type—choleric temperament; the inhibitable type—melancholic; the quiet, balanced type—phlegmatic; and the lively balanced type—sanguine.

[Dr. W. Horsley Gantt, in his Medical Review of Soviet Russia, which appeared in these columns from time to time during the last four years, makes frequent mention of Pavlov's work on conditioned reflexes. His first reference is in our issue of September 20th, 1924 (p. 533), where he deals with the work of Pavlov and his collaborators. In this article Gantt notes that the recent work of this school on "conditioned" reflexes had already received attention in the *British Medical Journal*, and refers to our report of the International Physiological Congress held in Edinburgh in July, 1923, at which Pavlov delivered a lecture on this subject (see *Journal*, August 11th, 1923, p. 256). The whole of Part I of Section VI of Gantt's "Review" is given up to Pavlov's work, and consists chiefly of a most absorbing account of his researches concerning conditioned reflexes in the dog (*Journal*, June 11th, 1927, p. 1070).]

SATURDAY, MAY 12TH, 1928.

## THE HARVEY TERCENTENARY.

NEXT week delegates from universities and medical societies throughout the world will meet in London to attend the celebrations promoted by the Royal College of Physicians of London in honour of the three hundredth anniversary of the publication of William Harvey's great work, the *De Motu Cordis*, in which he proved for all time his theory of the manner in which the blood circulated.

No pains have been spared to make this occasion fully worthy of the memory of Harvey, the great discoverer and the most distinguished Fellow on the roll of that College which now pays him homage. It is fitting that this gathering should be composed of representatives of all nations, for Harvey's work is the common heritage of the world at large, and for that reason this celebration recognizes no boundaries, either national or racial. All, therefore, will meet together next week on common ground to do honour to the man who conferred upon mankind one of its most signal benefits. The international character of the celebration is impressed upon every item of the programme. His Majesty the King has graciously consented to receive the delegates, thus setting his seal to the importance of the event. At the reception of the delegates at the College of Physicians by the President four creations of Honorary Fellows will be made which will be representative of those throughout the world who have contributed so largely in our time to the extension of the boundaries of medical and scientific knowledge. The three distinguished men—Sir Charles Sherrington, Professor Chauffard, and Professor Keibel—who will be called upon to deliver eulogies of the great work of Harvey will worthily represent the sum of medical and scientific endeavour wherever it exists, and at the dinner given by the College of Physicians in the ancient Guildhall of the City the gathering will represent all nations, all shades of opinion, and all classes. Not least of the ceremonies will be the scientific demonstrations given at University College by Sir Thomas Lewis and Dr. H. H. Dale on behalf of the College of Physicians. Here the actual experiments of Harvey will be repeated, and by means of a clever cinematograph film the audience will be able to see, almost, Harvey conducting his experiments as they were performed three hundred years ago. During the celebrations also an opportunity will be given to the delegates to inspect the treasures of the College of Physicians in the shape of books, manuscripts, portraits, and other objects of interest. Some of these relate to Harvey, such as his autograph letters, the diploma given him by the

University of Padua, the first edition of the *De Motu Cordis*, and the ebony pointer used by him for the purposes of demonstration when delivering the Lumleian Lectures in which he first announced the essential parts of his theory.

From the foregoing the magnitude of the celebrations will be manifest, but the importance of Harvey's discovery may not be so evident to all, and some may not be informed exactly concerning the far-reaching effects of his work. Indeed, there can be little doubt that while the central fact of Harvey's discovery of the circulation of the blood is well known to all, many are unaware that he overthrew a theory which had held the medical world in bondage for nearly fifteen hundred years. It becomes our duty, therefore, to describe certain features of medical thought existing before Harvey's time, in order to appreciate at its true worth the tremendous effect of his discovery, and to show how it opened the road down which successive investigators have travelled to reach our present-day triumphs in the realms of physiology and medicine.

Until the beginning of the sixteenth century all the knowledge possessed by the world concerning medicine and science was obtained from the ancient Greeks, and that knowledge had been finally systematized and reduced to order by Galen, who flourished during the second century A.D. After him medical and scientific thought slumbered for thirteen hundred years, and so paramount had his influence become that it was regarded as impious to question his authority. The result of this attitude was that medical writers were reduced to the sterile task of merely commenting upon what Galen had said, for to criticize, to doubt, or to inquire was not permitted. Indeed, so great was Galen's authority that John Geynes, a Fellow of the College of Physicians, was in 1559 threatened with expulsion for daring to impugn it. The writings of Galen deal with all branches of medicine, including anatomy and physiology, and he gave an explanation of the way in which the blood performed its function of carrying on the nutrition of the body. In order to understand the importance of Harvey's discovery it will be necessary to recall in some detail the main features of Galen's theory of the circulation of the blood, and the admirable description of that theory given by Dr. Charles Singer will be quoted. It is as follows: "The food taken into the body became converted into chyle by the intestines, and was carried by the portal vein to the liver, where it was changed into blood, becoming there endowed with the essence of all living things, which was called 'Natural Spirit.' The blood thus manufactured and endowed by the liver was carried by the hepatic vein and the inferior vena cava to the right side of the heart. Here it was purged of its impurities, which found egress by means of the pulmonary artery and the lungs to the external air. This venous blood, thus purified, ebbed to and fro in the veins and carried on the functions of nutrition. But a small part of the venous blood filtered through the septum of the heart, by means of invisible pores, into the left ventricle, where it came into contact with the external air, which had reached that chamber by way of the trachea, the lungs, and the pulmonary veins. By this contact with the air and the innate heat of the heart the blood became endowed with a higher form of spirit, termed the 'Vital Spirit,' and became arterial blood, which, ebbing and flowing in the arteries in the same way as the venous or crude blood, carried on its higher functions of nutrition. But the arterial blood which flowed to the brain became endowed there with the highest form of essence, known as 'Animal Spirit,' and was distributed to

the body by means of the nerves, which were believed to be hollow canals, and gave rise to the highest functions of motion and sensation."

From this description of the theory of Galen regarding the circulation of the blood it will be seen, therefore, that the main supports were: (1) the liver as the source of the veins and blood; (2) the communication between the right and left side of the heart through minute and invisible pores in the septum between the ventricles; (3) the presence of three vitalizing essences; and (4) the absence of any circular movement of the blood propelled by the heart. This was the theory of circulation, based partly on anatomy, partly on hypothesis, and fantastic in the extreme, which was accepted for more than a thousand years solely on the great authority of Galen. Until it was overthrown it postponed and fettered any advance in physiology, much in the same way as the theory of "phlogiston" held back any advance in chemistry.

So the position remained until the sixteenth century, when, under the influence of the revival of learning, the mind began to free itself from its bonds, and when men began to summon up courage to doubt and to inquire. The first attack made upon the authority of Galen came from the anatomical side in the year 1543, when Vesalius published his *De Humani Corporis Fabrica*, a book in which he described what he himself had seen when dissecting, and not what authority asserted. With regard to the septum of the heart Vesalius admits at first that the invisible pores must be there, although he could not see them; later, however, he says boldly that they do not exist. Columbus, Caesalpinus, and Servetus dealt with the lesser circulation, and Fabricius soon after described the valves in the veins. But they all lacked the power to draw the all-important conclusion. It was left for Harvey to make the discovery, and to give to the world the convincing proofs of his theory. This he did in his book, the *De Motu Cordis*, published three hundred years ago. His first position was to establish the primacy of the heart as the great factor in the circulation. From experiments and observation Harvey saw clearly that the heart was a muscular organ always propelling the blood it had received from the veins to the tissues of the body. Then he asked himself, Where did this blood thus propelled go, and whence came the blood in the veins to be carried to the heart? From quantitative estimations it was impossible to believe that the blood propelled by the heart could remain in the tissues, for he estimated that in an hour the heart propelled to the tissues more than the total amount of blood contained in the body. This observation forced on him the inevitable conclusion that the blood was always being propelled by the heart to the tissues, and that the same blood only could be carried back to the heart from the tissues by means of the veins; or, as Harvey says, "I began to think whether there might not be a motion, as it were, in a circle." With the adoption of this idea the direction and use of the valves in the veins became clear, and also the direction and use of the valves in the heart and arteries. The thesis was therefore proved, the victory won, and Harvey takes his lawful place beside his peers, Copernicus, Galileo, Newton, and Darwin. The sight of the blood passing through the capillaries was denied to Harvey, for the establishment of this fact was reserved for Malpighi, who was born in 1628, the year of the publication of *De Motu Cordis*. With that fact proved, the theory of Harvey concerning the circulation of the blood became unassailable and fixed.

This great achievement of Harvey had far-reaching consequences. Before his advent no progress could be made in physiology, for its foundations were faulty. But after the acceptance of his theory advance was rapid and sure, and it is not too much to assert that it is entirely owing to his illuminating discovery that such signal triumphs in medical and physiological science have been registered ever since. As a mark of our appreciation of the immense debt we owe to William Harvey, the great founder of modern physiology, we present to his memory next week the homage of the world.

## CONSULTANTS AND THE NATIONAL HEALTH INSURANCE BILL.

IN a leading article on April 21st last (p. 677) we suggested that the National Health Insurance Bill now before Parliament ought to receive from the medical profession, and especially from those practising as consultants or specialists, more attention than it seemed to be receiving; that in its present form it did not meet some of the most important requirements of the profession; and that an endeavour should be made by the British Medical Association, particularly by the Insurance Acts Committee, to secure satisfactory explanations, assurances, and amendments. This endeavour has been promptly made; but we are obliged to return to the matter because, though the Minister of Health has satisfied one such requirement, the position remains quite serious in other respects. The bill as introduced would have made it difficult, perhaps impossible, for an insured person to receive medical advice and treatment by way of additional benefit from a specialist or consultant except at some clinic or charitable institution. By reason of an amendment, suggested by the Insurance Acts Committee and accepted by the Minister, a more private mode of consultation will not be ruled out or discouraged. It will still require vigilance, however, in watching regulations and the clauses of suggested schemes to make sure that the Minister's own principle, that "no one must be compelled to go to a clinic if he would rather go to a private practitioner," is fully maintained.

Certain other amendments were suggested to the Minister which he has not felt himself able to accept. Yet if the object these amendments had in view is not by some means attained there may easily arise a situation which would not be consistent with the honour and interests of the profession, and in which the British Medical Association might have to advise its members not to take part in any, or in some particular, additional treatment benefit. The profession was of one mind in the earlier stages of national health insurance in saying that practitioners would not submit to the administration and control of approved societies, even though this were to be governed by Regulations which might be made by a Minister of Health. It is to be expected that it will be equally of one mind in saying that the freedom which it won for general practitioners shall not be withheld from consultants and specialists. The bill as it stands definitely endangers this freedom in the case of consultants and specialists, if it does not, indeed, make it impossible.

Under the present Act no additional benefit which is "of the nature of medical benefit" can be administered by an approved society. Of the existing additional benefits there is one only which is unquestionably of this nature. This has never been operative; and is to be abolished by the new bill.

Therefore, it is argued, the clause imposing this disability on approved societies may safely be repealed. Even so, the conclusion does not follow from the premisses; and in any case the principle enunciated by the clause is so valuable that it might well be allowed to stand even if it had no immediate application. But the soundness of the argument disappears—even the good faith of the argument seems to disappear—when it is discovered that in one of its schedules the bill introduces fresh words into the description of some of the other additional benefits which make them clearly, not only in the common acceptance of the language, but according to the most authoritative legal opinion, “of the nature of medical benefit.” “The payment of the whole or any part of the cost of treatment” may, as most lawyers agree, not be of that nature; but “the payment of the whole or any part of the cost of the provision of treatment” certainly is. Under this description, accompanied by the repeal of the restricting clause, it seems evident that approved societies, without resorting to the indirect and doubtful methods now employed, could themselves establish their own clinics for ophthalmic treatment under Clause 13 of the schedule, or for any other kind of specialist treatment under Clause 16. In this way they might be in a position to select and control staffs, medical and other, and largely to determine the character of the treatment to be carried out.

It is not suggested that the best of the approved societies would wilfully abuse their powers; and it is quite true that under the bill they would not be completely free to do as they liked, but would be governed by Regulations to be made by the Minister of Health. It is not suggested, either, that the Regulations would be unreasonable or improper, or that the profession, through the British Medical Association, would not be consulted with regard to them or be without its influence upon them, as is now the case. In the event contemplated such regulating would be not only useful, but imperative. The protection of Statute Law is, however, better than the protection of Regulations; and the consultants and specialists cannot contemplate with equanimity a state of affairs which would compel them either to abandon a legitimate sphere of practice or to submit to objectionable conditions which the experience of another branch of their profession has proved to be intolerable.

Either the words “the provision of,” italicized above in the description of additional benefits, should be deleted, or the restricting subsection of Section 75 of the Act of 1924 should be allowed to stand, or should be so amended as to maintain the principle that when an additional benefit is of the nature of medical benefit, in whatever other way it may be administered at least it shall not be administered by an approved society. The present situation is a serious one for a considerable section of those engaged in consultant and specialist practice. The importance of securing, if it be possible, one or other of these amendments is great, not only to them, but to the whole profession, in order to maintain its traditions and independence intact. Even if there be failure to secure such amendments it will, of course, still be possible for the profession to withhold its services from a society or to refuse to give medical advice and treatment under Regulations to which it objects; but it may yet be that a realization of the position and of the reasonableness of the request may lead the Government or Parliament to avoid such an undesirable situation. To secure this, however, the profession must itself be not merely alert, but active. “It is not enough to will, we must also do.”

## GLAUCOMA.

It is only a few generations since physiology was considered an unimportant fragment in the subject of anatomy, and hardly more than one generation since biochemistry was barely recognized as an entity at all. To-day the whole of the structure of medicine and surgery is slowly being consolidated on the basis of physiological facts, and physiology itself is being interpreted and studied more and more through the medium of the still more fundamental science of biochemistry. There are few problems of pathology where this tendency is seen more evidently than that of the etiology of glaucoma. For years it has been the subject of inquiry and investigation; but so long as work has been directed along the lines of pathological anatomy and gross end-results, the problem has remained obscure. In his suggestive lecture, which appears in this issue, Dr. Maitland Ramsay has indicated how the trend of recent work is throwing new light upon the matter, and although the problem is not by any means solved as yet, although it may not even be ultimately solved in this way, it is undeniable that some deeper insight into it is being gained, and some advances have been made which cannot but bear fruit.

Before the causes of pathological rises of intraocular pressure can be adequately understood, it is obviously essential that the factors which govern the maintenance and variations of this pressure under normal conditions should first be made clear. This is a question upon which it cannot be said that all authorities are agreed; but the evidence recently deduced from biochemical studies seems to point very definitely to the thesis that there is little in the physiology of the eye which differs from the physiology of the other parts of the body. It would seem most probable that the intraocular fluids are, like the tissue fluids, that the intraocular circulation is governed by the same general principles as the general circulation; and that the apparent anomalies seen in the eye are merely physiological adaptations based on general biological principles such as are shown by every organ in order that it may satisfy its own peculiar needs. As Dr. Ramsay aptly puts it, “although peculiarities of structure are necessary for the architecture of the different organs of the body, yet it is one and the same physiological process which regulates and controls their vital activities.”

An interference with the circulation of the blood through the eye, and the consequent change in the nature of the intraocular fluids, are two of the outstanding features in an attack of acute glaucoma, and all the evidence points to the conclusion that the essential cause of the changes is to be found in that part of the circulation through which all vital changes take place—the capillaries. The first step is a disturbance in this part of the circulation, leading to general dilatation of the capillary walls, accompanied by an increased permeability. What the cause of the disturbance is remains as yet obscure; presumably it is to be sought in the general health and metabolism of the patient rather than in the eye itself. Most probably it is chemical in nature, perhaps hormonal, or due to some substance of the histamine group, as Dr. Ramsay suggests; whatever its nature its action is a dilatation of the capillaries, an increased permeability of their walls, and an oedema of a plasma-like fluid into the tissue spaces of the eye, with a consequent rise of pressure.

The matter, however, is not so simple as to be without any other complicating factor. Physio-

logically the intraocular pressure is changed by factors other than the state of the capillaries, and pathologically great rises of tension can be met with in cases wherein the entire uveal tract, containing the great mass of ocular capillaries, is compressed almost out of existence by something else. The appearance of a glaucomatous eye, with the lens pushed forwards and the anterior chamber shallow, suggests forcibly that this factor is a swelling of the vitreous. This substance is a colloid, and it is found under experimental conditions to be capable of a considerable amount of swelling; but the conditions determining the volume changes of such a mass are as yet imperfectly known. Colloid chemistry is a science even younger than biochemistry. Here again the causal factors are chemical in nature, most probably of general metabolic origin, and their assessment and elucidation is one of the most interesting and important applications of biochemistry, which must in the meanwhile be left to the future. The trouble is that "glaucoma" is not a disease, but a symptom common to many diseases, and it is illogical to look for an explanation of every rise of intraocular pressure along the same lines. It is one of those problems which become more complicated the more they are investigated, but which for the same reason become more fascinating.

#### "FRIENDS OF THE OLD ASHMOLEAN."

A SOCIETY of Friends of the Old Ashmolean was formed at a meeting held at the house of the Royal Society of Medicine on May 2nd, under the chairmanship of Sir Humphry Rolleston. The purpose of the society will be to assist in the restoration of the Old Ashmolean building at Oxford as a public Ashmolean Museum of the history of science. The gift to Oxford about five years ago of the Lewis Evans collection of scientific instruments has made the scheme possible, and it is hoped to provide, by means of annual subscriptions, for the purchase of desirable objects of historic scientific interest to add to the collection. The University has shown approval by allotting the upper room in the Old Ashmolean building for this purpose, and several of the colleges and certain city companies have given financial assistance. But it is hoped that the new society may render further assistance in the acquisition and conservation of objects of scientific and medical interest, besides securing the Old Ashmolean wholly as a scientific institution in the University, just as Sir Thomas Bodley restored the library that now bears his name. Sir Humphry Rolleston reminded the gathering that the Old Ashmolean was named after and provided with a local habitation by Elias Ashmole, the famous antiquary, in 1683. This had the distinction of being the oldest museum for natural history in the kingdom. Its recent rebirth as the Lewis Evans collection of scientific instruments was due to Mr. R. T. Gunther, who, among many other acts of devotion to science in Oxford, collected the old scientific instruments for exhibition for the presidential address given before the Classical Association in 1919 by Sir William Osler, "who being dead yet speaketh." Mr. Gunther then gave some details of the aims and purposes in achieving what the chairman had called "this pious act," and said that the Lewis Evans collection was in urgent need of more space. The present time was favourable for the restoration of the building. The great *Oxford English Dictionary* was completed, and the book stacks which had blocked up the rest of the exhibition space in the old museum might readily be evacuated as part of any Bodleian extension scheme; two such schemes were now under consideration. Sir Humphry Rolleston, in a few further remarks, discussed some special

reasons in favour of the project. Knowledge of a science, he said, was incomplete without an acquaintance with the history of its development to supply guidance in avoiding pitfalls and fallacies, and to suggest fresh avenues for investigation. For such a history recourse was usually made to books, but a museum was another source of information, and in some ways the complement of a library. Not only in the sciences but in the arts was a museum displaying instruments and machinery of great value. Medicine, struggling to become some day an exact science, was or should be an applied science, and a collection of instruments illustrating the way in which the applications of science had led to its advance was beyond question most instructive. Sir Humphry gave one example of the way in which instruments of precision had not only added to knowledge, but stimulated investigation—namely, Laennec's introduction in 1819 of auscultation by means of the stethoscope. Auscultation had been practised before that date, but psychologically the possession of a new instrument served as a spur to Laennec to pay most careful and prolonged attention to the sounds that could be heard in the chest. It was much the same with regard to Piorry's pleximeter and mediate percussion, which in itself, and apart from its temporary influence in stimulating investigation, was inferior as a method of eliciting physical signs to Auenbrugger's long-neglected direct percussion, which it was intended to supersede. The debt cardiology owed to the polygraph, the electro-cardiograph, the orthodiascope, and the sphygmograph need not be laboured, nor, in other fields, the value of the thermometer, the microscope, and so forth. Medicine owed heavy contributions from the more exact sciences, and depended for its advance largely on their assistance. In return for these gifts it was meet and right that medical men, not only those interested in its history, but all who looked to its future with a lively sense of benefits to come, should contribute of their sympathy in a practical form. The scheme was then supported in short speeches by Dr. E. B. Knobel, speaking from the point of view of astronomy; Dr. W. T. Calman, from that of zoology; Dr. A. G. Gibson, pathology; Sir George Fordham, cartography; and by Professor A. F. Boycott and others. The resolution approving of the formation of a Society of Friends of the Old Ashmolean was moved by Sir D'Arcy Power and seconded by Dr. Dixey, and carried. Among those who sent letters of regret at inability to be present and approved the purpose of the gathering were Lord Crawford, Sir Farquhar Buzzard, Sir Archibald Garrod, and Professor G. Elliot Smith. It is understood that a meeting of the new society will be held annually at Oxford, when accessions to the collections will be exhibited. The minimum subscription is 5s. a year; it may be sent to the Treasurer of the Friends of the Old Ashmolean, at Barelays Old Bank, Oxford.

#### WELFARE OF THE BLIND.

THE seventh annual report of the Advisory Committee on the Welfare of the Blind to the Minister of Health shows that there is increasing knowledge of and care of the blind in this country. There has been a growing tale of the blind, due without doubt to the discovery of cases brought about by recent legislation. There are known to be 17,232 blind persons between the ages of 50 and 70 years, and of these no less than 84 per cent. are in receipt of benefits under the Blind Persons Act. The annual value of the pensions granted is £364,000. This sum, together with the Exchequer grants payable in respect of specific services for the blind, represents a very substantial State contribution towards the cost of making provision for the blind. The State grants and pensions have released voluntary funds for other purposes, such as the relief of blind persons

<sup>1</sup> Seventh Report of the Advisory Committee on the Welfare of the Blind, 1924-27. London: H.M. Stationery Office, 1928. 6d. net.

not eligible for pensions. Under the Act local authorities were empowered to promote schemes for the welfare of the blind; 146 such authorities have submitted schemes which have been approved. Most have elected to act through the existing local voluntary societies, and it is found in practice that these schemes are the most successful where there is an active local society and use is made of it. The introduction of State and rate-aided services for the blind has not had the effect of reducing voluntary subscriptions and donations. The register of the blind for England and Wales now shows a total of 46,822 persons, or 1 in 835. This is the highest ratio yet recorded. It is held that the increase is more apparent than real. The passing of the Wireless Telegraphy (Blind Persons' Facilities) Act of 1926 has led to the discovery of a considerable number of blind persons who were unregistered. It is noteworthy that the increases in numbers are shown in the older age groups, whereas in the age group below 21 years there has been a small decrease. This decrease is encouraging, as it seems definitely to indicate that the measures in operation for the prevention of infantile blindness are restricting the number of persons who become blind in the early years of life. In the latest return 62.3 per cent. of the blind are over 50 years of age, as compared with 59.1 per cent. in 1925, 56 per cent. in 1923, and 52 per cent. in 1921. Despite the decrease in the earlier years, the largest proportion still become blind in the first year of life, and the next largest between 60 and 70 years of age. Statistics of employment show that there has been a diminution of unemployed blind persons. There has been an increase in the number under training, and a fall in the number for whom training cannot be found. The unemployable is by far the heaviest total, and an increasing one. Paragraph 16 of the report may be quoted *in extenso*: "In connexion with the registration of the blind, the inclusion of new entrants in grant-aided service, and for other purposes, voluntary agencies find it necessary to obtain medical certificates as to visual conditions, and in some areas the arrangements made for obtaining such certificates would not appear to be altogether satisfactory. We are informed that in connexion with the provision of pensions under Section 1 of the Blind Persons Act, 1920, the Ministry are prepared to arrange, if considered to be necessary, for the medical examination of cases where either the pension officer or the applicant appeals on ground of blindness against the decision of the local pensions committee. We gather, however, that the onus of securing the medical certificates for other purposes—for example, registration—rests with the voluntary agency or the local authority. In a number of areas the local authority have, through their own special staff or by agreement with the local ophthalmic specialists, made arrangements for the certification of blind persons receiving benefit under their scheme under Section 2 of the Blind Persons Act, 1920, and we would recommend other local authorities to consider the advisability of adopting this practice where the voluntary agency conducting services on their behalf experience difficulties in regard to the certification of the blind."

#### THE HEALTH ORGANIZATION OF THE LEAGUE OF NATIONS.

THE work done by the Health Organization of the League of Nations becomes each year of greater importance, and the report for 1927, just issued, contains a mass of information of activities pursued in many parts of the world. One very extensive piece of work carried out at Geneva consists in the collection of epidemiological intelligence and public health statistics. The Health Section publishes a *Weekly Record* and a *Monthly Epidemiological Report*, and at a conference held at Geneva in October last the question of the transmission of epidemiological

intelligence by means of telegraphic code and by wireless broadcast in code or in clear was carefully considered. The Eastern Bureau of the Health Organization at Singapore carries out for the East what Geneva does for the rest of the world, and is in weekly communication with 140 ports. This bureau also receives information with regard to the arrival of infected ships at certain ports, and acts as a co-ordinating centre for certain research problems. Another important part of the work of the League's Health Organization is the interchange of public health officers and facilities for advanced study and training in public health and hygiene. A course in Paris in January, 1927, was attended by twenty-six health officers of fifteen different countries, and a second course was held in London towards the end of the year. Besides these international public health courses, two regular interchanges of public health officers were held in 1927, the first in Great Britain and the second in Germany. The work of the various commissions of the Health Organization is reported in some detail. The Malaria Commission has issued a very important report on the control of malaria in Europe, and steps are being taken to carry out an effective campaign against malaria among the Bulgarian refugees in the Burgas region, where the Health Organization of the League and the International Health Division of the Rockefeller Institute are co-operating. The Sleeping Sickness Commission has completed its work in equatorial Africa, and an extensive and detailed report is shortly to be issued. This report has been studied by a commission of experts, and it is proposed to inquire whether a second international conference on sleeping sickness (the first was held in London in 1925) shall be called to consider the final report and the opinion of the commission of experts. During the past year important steps have been taken with regard to co-ordinating the work of the Health Committee with that of the permanent committee of the Office International d'Hygiène Publique, and in future it is hoped that the two committees will be of more assistance to each other. International health matters have scarcely a spectacular appeal, but as the work of the various organizations gains in experience it is becoming more obvious how national health matters are bound to reap benefit.

#### TUBERCULOSIS IN FRANCE.

PERIODICALLY the medical profession in various countries launches a fresh attack on tuberculosis. The first move in the campaign is the assertion that the country is behind its neighbours in the public provision made for the treatment of the disease. Yet it may be doubted whether adequate statistics, showing the comparative incidence and mortality in different countries, with due allowance for fallacies, have ever been prepared; it is possible that the difficulties in obtaining such a comparison are insuperable. In any case, further evidence seems desirable before the Frenchman allows *La Vie Médicale* to make his flesh creep by means of the two statements used as texts for its special number on prophylaxis in infancy against tuberculosis. This journal, which is officially connected with the general association of French practitioners of medicine, adorns the title-page of a recent issue with two assertions: Denmark spends two gold francs per head of population on its antituberculosis campaign; France spends forty paper centimes. The articles in *La Vie Médicale* do not, however, tell us whether the results in the public health correspond with these figures. Thus Dr. René Mainot's statement that France is forty-first in the list of countries arranged according to the excess of births over deaths does not necessarily mean that the position is due solely to infantile mortality from tuberculosis. Dr. Mainot seems to suggest that in Denmark, England, and the United States tuberculosis has receded as the result of the provision

of special beds for the tuberculous; and he thinks that France needs 40,000 more beds, at a cost of 880 millions of francs! Surely a proposition like this requires the careful consideration of all possible figures of incidence and mortality in various countries before salvation is sought at such a cost. Moreover, it would be interesting to learn how far the removal of sources of infection to special beds is likely to excel the Grancher system and Professor Calmette's vaccination with B.C.G. The boarding-out of the very young is dealt with in an article in *La Vie Médicale* by Professor Léon Bernard, and Dr. G. Poix writes on the results of 'six years' preventive vaccination against tuberculosis. It is evident that many doctors in France are looking to preventive vaccination as a means of largely reducing the mortality from tuberculosis.

#### NON-TUBERCULOUS FIBROSIS OF THE LUNG IN CHILDREN.

ANY method of differentiating tuberculous and non-tuberculous primary fibrosis is always of great interest. In a paper in the February issue of the *Archives of Disease in Childhood* Drs. Agassiz and Gill reported the results of the study of a number of cases of non-tuberculous fibrosis in children. In the 37 cases examined there was a family history of tuberculosis in 2 only; there was also a previous history of measles, whooping-cough, or pneumonia in a large proportion. The authors are inclined to distinguish between pulmonary fibrosis and bronchiectasis, and they suggest that since fibrosis precedes bronchiectasis it is possible that the former may exist without the latter. They found that cough was frequent, expectoration slight, dyspnoea not complained of, haemoptysis rare, and cyanosis a constant sign of this disease. The temperature charts were normal, except for an occasional rise when a portion of the lung became inflamed in non-tuberculous fibrosis, while in tuberculosis the temperature was as a rule constantly above normal. X-ray examination revealed a deflection of the mediastinal contents in non-tuberculous fibrosis, and the basal lobes were more commonly affected. In tuberculosis there is a mottling or wooliness throughout the lung, more marked in the region of the apex. Examining the blood for its oxygen content, these authors conclude that in fibrosis the blood oxygen content is diminished, whereas in tuberculosis the blood oxygen content should be normal except in massive infection of the lung. In fibrosis where tuberculosis develops later the oxygen content should increase with the advance of the tuberculosis, whereas in a healing and fibrosing tuberculous condition the blood oxygen content should decrease as healing proceeds. They believe that the prognosis of non-tuberculous fibrosis of the lungs is very much better than that of pulmonary tuberculosis. Ordinary open-air treatment in convalescent homes or sanatoriums for children is very suitable in this disease.

#### INTERNATIONAL CONFERENCE ON CANCER.

As announced in our issue of April 14th (p. 640), an International Conference on Cancer, convened by the British Empire Cancer Campaign, will be held from July 16th to 20th in London, at the house of the Royal Society of Medicine. Physicians, surgeons, pathologists, and radiologists from all parts of the world whose work has been closely associated with inquiry into the causes and cure of cancer will attend, and the Royal Society and all the principal universities, medical schools, and scientific bodies of this country have appointed delegates. Sir John Bland-Sutton, Bt., vice-chairman of the Grand Council of the

Campaign, will preside, and Sir Richard Garton, chairman of the Finance Committee, is acting as honorary secretary of the Conference. On Wednesday, July 18th, H.R.H. the Duke of York, President of the Campaign, and the Duchess of York will receive the delegates and their wives at Lancaster House (Landon Museum), which has been lent by the trustees for this purpose.

#### ROCKEFELLER MEDICAL FELLOWSHIPS.

THE Rockefeller Medical Fellowships for the academic year 1928-29 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 1st next. These Fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation. Fellowships are awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. A Fellowship will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance. Travelling expenses and some other allowances will be made in addition. Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C.2.

DR. GEORGE H. F. NUTTALL, F.R.S., Quick Professor of Biology in the University of Cambridge, has been elected a foreign corresponding member of the Academy of Medicine, Paris.

THE annual general meeting and conversazione of the Medical Society of London, arranged for Monday, May 14th, has been postponed to Monday, May 21st, when Sir Archibald Garrod will deliver an oration entitled "Lessons on rare maladies" at 9 p.m.

THE Royal Society of Tropical Medicine and Hygiene will celebrate the twenty-first anniversary of its foundation by a dinner at the Café Royal on Wednesday, June 20th, at 8 o'clock, when the Right Hon. L. S. Amery, M.P., Secretary of State for Dominions and for the Colonies, will be the principal guest.

As we go to press we have received a report, prepared for the Ministry of Health by Dr. J. Alison Glover, on non-specific chronic arthritis, with special reference to the provision of treatment.<sup>1</sup> This is the third of a series of reports from the same pen concerned with public health preventive aspects of the so-called "rheumatic" diseases. The first, which dealt with the incidence of these disabling conditions in adult insured persons, was noticed in our columns on March 1st, 1924 (p. 395). The second dealt with acute rheumatism in childhood in its relation to heart disease, and was reviewed on July 30th, 1927 (p. 187). Like these earlier documents, the present one is intended both for the use of medical practitioners and for the guidance of the lay public. An appendix by Dr. R. Fortesque Fox and Dr. Margarethe Mautner describes the treatment of rheumatic diseases by physical methods in Germany. We hope to notice the report in some detail in an early issue.

# The Harvey Chapel at Hempstead.

BY THE LATE

SIR DAWSON WILLIAMS.

WILLIAM HARVEY died in his eightieth year on June 3rd, 1657, at the house of his brother Eliab at Roehampton. This brother had, about the year 1647, acquired by purchase from Sir Charles Mordaunt the Manor of Winslow (or Wincelow) at Hempstead a small Essex village situate about seven miles east of Saffron Walden and some fifty miles from London. The church, in which is a chapel known as the Harvey Chapel, was originally a Norman structure, dating from the reign of William Rufus, who in 1089 settled it on Battle Abbey, Sussex. A late Norman font and fragments of the

Norman chancel are preserved in the existing church. The church was rebuilt about the year 1340 in the Decorated Gothic style, the four clustered pillars, supporting pointed arches, separating each of the aisles from the nave, being highly ornamental and beautiful. The Harvey Chapel, on the north side of the chancel, is a plain rectangular brick building, with a high-pitch tile roof, and lighted by a large triple-light window. This chapel contains sixteenth century memorial brasses of a date prior to its association with the Harvey family. Beneath the chapel Eliab Harvey had in the year 1655 built an outer vault

as a sepulchre for his family; and it was here, as we shall see, that the mortal remains of the great William Harvey were first laid. The fabric of the Early English church still exists, except that about one-third of the west end of the nave was destroyed when the tower fell in 1881, and was rebuilt in 1884 at the cost of upwards of £2,000.

The church contains altogether some nine brasses dating from 1472 to 1530, to representatives of families resident at the three ancient manors of the parish. The memorials to members of the Harvey family in the chapel begin with Eliab, who owned and occupied one of these manors, his wife, and children, and descend to another William Harvey and his wife, whose features are shown in a pair of very striking medallion portraits by Koubiliac, the famous sculptor. There is also a fine memorial tablet to Admiral Sir

Eliab Harvey, who was in command of the *Téméraire*, chosen by Lord Nelson to be his supporting ship at the battle of Trafalgar. The earliest memorial in the church is the exceedingly interesting thirteenth century marble tablet in the floor of the chancel with a Norman-French inscription, decipherable only by the indentations in the stone from which the inlaid lettering has been displaced and lost. The reading is: " Dame Margerie de Basinggè gist ici Dieu de sa alme cit merci Amen "; in English, " Lady Margerie de Basing lieth here: May God upon her soul have

mercy. Amen."

Again, another interesting relic is an heraldic helmet set on an iron bracket above the pulpit, surmounted by the Harvey crest—a hand supporting a crescent at the finger-tips.

The sarcophagus containing the remains of William Harvey himself is within the chapel, but the monument to him is just outside on the north wall of the nave. It consists of a marble bust, with his arms above, and a long and laudatory Latin inscription below. The bust is set in a niche, over which is a small arched pediment having, upon its rising sides, two cupids in posture of distress, one of which is represented holding in his hand a death's head. The

Marble sarcophagus containing the remains of William Harvey. Erected by the Royal College of Physicians in Hempstead Church, Essex, 1693.

monument is a composition of black and white marble, veined. Sir Benjamin Ward Richardson, who took a great interest in all that pertained to the last resting-place of Harvey, came to the conclusion that this bust had been copied from a cast of the face of Harvey taken after his death; in this opinion he was supported by Mr. Woolner, R.A., who visited the church in 1878.

Eliab, who was Harvey's executor, resolved that his brother's body should be placed in the family vault he had constructed. The funeral started from London on June 26th, and was followed far beyond the City walls by a large number of the Fellows of the College of Physicians.

Harvey's body was simply wrapped in lead without a coffin, which seems to have been a custom peculiar to the Harvey family. The leaden case used for

William Harvey was roughly shaped in the form of a body, having a head, neck, and shoulders, from which it gradually tapered towards the feet, where it was turned up at a right angle. It had a broad breastplate with the following inscription in raised letters:

DOCTOR  
WILLIAM HARVEY  
DECEASED THE 3  
OF JUNE 1657  
AGED 79 YEARS.

When visited in 1847 by Richardson, and again in 1859 and 1868 by Dr. A. P. Stewart and Dr. (afterwards Sir) Richard Quain, the leaden shell lay upon

The original memorial to Harvey (1657) upon the wall at the entrance to the Harvey Chapel in Hempstead Church.

the floor just beneath a small window in the eastern wall. The suggestion arose that the remains should be removed to Westminster Abbey, and was favoured by Dean Stanley; but he was then in failing health, and nothing was done until matters were brought to a crisis in January, 1882, by the fall of the tower of the church. No damage was done to the Harvey Chapel, but the College of Physicians decided to take some action. Sir Benjamin Ward Richardson reported to the College in February, 1882, that the lead of Harvey's shell was going fast, and suggested that the remains should be raised to the Harvey Chapel above the vault. The College appointed a committee, consisting of Sir William Jenner (President), Sir James Risdon Bennett, Sir Henry Pitman, and Drs. Sieveking, Richardson, Frederick Furre, Quain, and A. P. Stewart. It was decided to keep the remains at

Hempstead, but to remove them to the Chapel above the vault and to place the leaden ease in a sarcophagus. The floor of the Chapel was strengthened by pillars built in the vault, and a plain sarcophagus of pure white Carrara marble provided. The memorial was designed and carried out by Maile and Sons of Euston Road.

The following inscription was placed at the head of the sarcophagus:

WILLIAM HARVEY  
Born 1578. Died 1657.

The following was engraved on one side:

The remains of William Harvey  
Discoverer of the Circulation of the Blood  
were reverentially placed in this sarcophagus by  
the Royal College of Physicians of London  
in the year 1883.

A leaden ease was also prepared, in which was placed the edition of the works of Harvey published in Latin by the Royal College of Physicians of London in 1766, and edited by Drs. Akenside and Lawrence. On one side of this was engraved:

GULIELMI HARVEII  
Opera Omnia  
Edita  
MDCCLXVI.

On the other side was inscribed:

The complete works of William Harvey  
deposited October 18th, 1883.

A memorial bottle, hermetically closed, was also prepared and was wrapped in lead. In it was placed a memorial, engrossed on vellum by Messrs. Harrison of St. Martin's Lane. The leaden case enclosing the bottle had inscribed upon it:

SCROLL

Deposited October 18th, 1883.

The following is a copy of the memorial itself:

"The body of William Harvey laid in lead simply soldered was laid without shell or enclosure of any kind in the Harvey Vault of this Church of Hempstead Essex, in June 1657.

"In the course of time the lead enclosing the remains was from exposure and natural decay so seriously damaged as to endanger its preservation rendering some repair of it the duty of those interested in the memory of the illustrious discoverer of the circulation of the Blood.

"The Royal College of Physicians of which corporate body Harvey was a munificent Benefactor and which by his favour is the possessor in perpetuity of his patrimonial Estate at Burmarsh, Kent, did in the years 1882-83 by permission of the Representatives of the Harvey family undertake that duty.

"In accordance with this determination the leaden mortuary chest containing the remains of Harvey was repaired and as far as possible restored to its original state and on this 18th day of October 1883 in the presence of four Representatives of the Harvey family and of the President, all the office-bearers and many other Fellows of the College of Physicians (whose names are hereto appended) was reverently translated from the Harvey Vault to this Sarcophagus raised by the College for its reception and preservation."

The scroll was signed by four members of the Harvey family, and by the President, Censors, Treasurer, Registrar, Harveian Librarian, and a number of Fellows of the College, who attended at Hempstead on St. Luke's Day (October 18th), 1883. The leaden coffin was then raised to the churchyard and carried up the nave and aisle into the Harvey Chapel, the pall-bearers being eight Fellows of the College, of whom the last survivor was Sir Dyce Duckworth, who died last January. At the conclusion

of a short service the leaden shell was lowered into the sarcophagus, and the President of the College placed the case containing the scroll in a glass bottle and the metal box containing the copy of Harvey's works also in a bottle, beside the leaden coffin in the interior of the sarcophagus.

*Note.*—Sir D'Arcy Power says, in his Masters of Medicine Series, that the marble monument containing the bust of William Harvey is "high in the wall of the Church at Hempstead." The ornamentation of the tablet is bold and effective, and below the bust is a long Latin inscription. He quotes from the report of Mr. Thomas Woolner, R.A., as follows: "The features presented by the bust are clearly those of a dead face. The sculptor exhibits no knowledge of sculpture except when he was copying what was directly before him. With the cast of the face for his copy he has shown true artistic delineation, but all that he has been obliged to add to make up the bust as it stands is of the worst possible quality. The ears are placed entirely out of position, the large redundant head of hair is altogether out of character, imaginary, and badly executed, and the drapery of the shoulders is simply despicable."

The Latin inscription upon the original memorial to Harvey reads:

GULIELMUS HARVEIUS  
Cui tam colendo Nomini assurgunt omnes Academiae  
Qui diurnum Sanguinis motum Post tot Annorum  
Millia Primus invenit  
Orbi Salutem Sibi immortalitatem  
Consequutus.  
Qui ortum et generationem Animalium Solus omnium  
A Pseudophilosophia Liberavit  
Cui debet  
Quod sibi innotuit humanum genus Scipsam medicina.

Assiduus, et foelicissimus  
Quibus Illustrem Construxit Bibliothecam  
Suog. Dotavit et Ditavit Patrimonia.  
Tandem  
Post triumphales  
Contemplando, Sanando, inveniando,  
Sudores,  
Varias domi forisq. Statuas Quum totum cirevit  
Microcosmum Medicinae Doctor ac Medicorum  
Improles Obdormiuit.  
III<sup>o</sup> Junii Anno Salutis MDCCLVII, Aetatis LXXX<sup>o</sup>  
Annorum et Famae Salut.  
RESURGEMUS.

Of this a liberal English translation (by the Rev. T. Conyers Barker, M.A., Vicar of Hempstead) is as follows:

WILLIAM HARVEY  
to which honoured name all the Universities  
pay the greatest veneration:  
Who after so many thousand years first discovered  
the constant circulation of the blood,  
obtaining thereby health to the world and immortality to  
himself  
Who alone of all men rescued the birth and generation of animals  
from false philosophy,  
To whom mankind are indebted for the knowledge of medicine  
itself,  
Chief and dearly-loved physician to their Serene Majesties  
James and Charles, Kings of Britain;  
Diligent and successful professor of anatomy and surgery in the  
College of Physicians at London,  
for whom he erected, and endowed with his own estate,  
a magnificent library.  
At length  
after labouring with success in his studies, in his practice, and in  
his discoveries,  
And after many statues had been erected both at home and  
abroad,  
When he had encompassed the whole order of Medicine and of  
Medical Science, this learned man  
died without issue on the Third of June in the year of our  
Lord 1657, of his age the 80th,  
Full of Years and Honour.  
WE SHALL RISE AGAIN.

## HARVEY TERCENTENARY CELEBRATIONS.

MAY 14TH TO 18TH, 1928.

Through the courtesy of the President and Registrar of the Royal College of Physicians of London we have received an advance copy of the full programme for the tercentenary celebration next week of the publication of *De Motu Cordis* by William Harvey. This programme is a beautiful document, printed in pamphlet form, with three fine photographic plates, one being a reproduction of Harvey's portrait by Jansen, the second showing the Arms of the College, after Richard Wallis's design, and the third showing the College Insignia displayed on their tasselled velvet cushion. The whole work has been carried out with reverent care by Mr. Emery Walker at his Hammersmith press. The text includes a short account of Harvey's life and work, an historical note on the College and its possessions, and an imposing list of the delegates from twenty-one foreign countries, from the Dominions beyond the seas, and from the British Isles, who will be received by the King at Buckingham Palace on Monday morning and will take part in the other ceremonies. Besides these official delegates, ninety in number, from universities, colleges, and scientific bodies at home and abroad, Harvey's birthplace will be represented by the Mayor of Folkestone; his school by the late Headmaster of King's School, Canterbury; his hospital by the Treasurer of St. Bartholomew's; his College at Cambridge by the Master of Gonville and Caius; Merton College, Oxford, by his successor to-day in the office of Warden; and the Harvey family by the Rev. Rosendale Lloyd. The delegate of the British Medical Association is its President, Sir Robert Philip.

At the reception to be held by the Royal College of Physicians on Monday afternoon four eminent men will be admitted as Honorary Fellows—the Earl of Balfour, K.G., O.M., F.R.S., Sir Ernest Rutherford, O.M., President of the Royal Society, Professor Pavlov of Leningrad, and Professor Wenclebach of Vienna—and short eulogies of Harvey will be delivered by a physiologist, Sir Charles Sherrington, O.M., F.R.S., a physician, Professor A. Chauffard of Paris, and an anatomist, Professor Franz Keibel of Berlin. The other functions during the week are indicated in the abridged time-table printed below. After the luncheon party at St. Bartholomew's, Sir Wilmot Herringham will give an account of Harvey's connexion with that hospital. The visit to Cambridge will be followed by a meeting of the Physiological Society to be held there on Saturday. The Harvey tercentenary will be celebrated in Paris on the following Tuesday, May 22nd, at a commemorative function arranged by the Académie de Médecine.

### TIME-TABLE.

Monday, May 14th.

- 11 a.m.—Reception of Delegates by His Majesty the King at Buckingham Palace.
- 3 p.m.—Reception of Delegates and distinguished guests by the College of Physicians at the Addresses by Delegates. Eulogies of Harvey.
- 6.30 for 7 p.m.—Dinner given by the Grocers Company at Grocers' Hall.
- 9 p.m.—Lady Bradford "At Home" at 8, Manchester Square.

Tuesday, May 15th.

- 10.30 a.m. to 12.30 p.m.—Demonstrations arranged by the Royal College of Physicians in the Physiological Department of University College. A reproduction of Harvey's original anatomical dissections by cinematograph. Demonstrations of the circulation of the blood.
- 1.15 p.m.—Luncheon at St. Bartholomew's Hospital given by the Governors of the Hospital.
- 4 p.m.—Tea at the Royal College of Physicians with exhibition of books, MSS., pictures, silver, and other objects of interest.
- 9 p.m.—Conversazione at Merchant Taylors' Hall by permission of the Court of the Company. H.R.H. the Prince of Wales has consented to be present.

## Wednesday, May 16th.

10.30 a.m. to 12.30 p.m.—Demonstrations arranged by the Royal College of Physicians in the Physiological Department of University College.

6.30 p.m. for 7 p.m.—Dinner given by the President and Fellows of the Royal College of Physicians in the Guildhall of the City of London.

## Thursday, May 17th.

Morning and Afternoon.—Visit to Oxford by invitation of the Warden and Fellows of Merton College.

8.30 p.m. to 11 p.m.—Reception at the Rooms of the Royal Society, Burlington House, by the President of the Royal Society.

## Friday, May 18th.

Morning and Afternoon.—Visit to Cambridge by invitation of the Master and Fellows of Caius College.

## DEMONSTRATIONS AT UNIVERSITY COLLEGE.

The following demonstrations, arranged by the Royal College of Physicians, will be given at University College, Gower Street, W.C., on the mornings of Tuesday, May 15th, and Wednesday, May 16th.

At 10.30 a.m. each day there will be an exhibition of a cinematograph film of Harvey's experiments, prepared by Sir Thomas Lewis and Dr. H. H. Dale. At 11.30 the following demonstrations illustrating recent additions to knowledge of the circulation will be given:

1. Professors Lovatt Evans and Verney will give a demonstration of "the isolated mammalian heart-lung preparation." The preparation to be shown is one devised by the late Professor E. H. Starling for the purpose of studying the reactions of the mammalian heart to measurable changes in the conditions under which it is working. The heart and lungs are completely isolated from the rest of the animal, the normal peripheral circulation being replaced by a system of tubes representing its arterial, capillary, and venous components. The rate of inflow of blood into the right auricle, the temperature and composition of this blood, as well as the peripheral resistance against which the left ventricle works, can be varied and measured at will. Further, the effect of variations in any of these factors on the volume of the heart, on its rate of beating, and on the coronary flow, may readily be studied. The demonstration is designed primarily to show the nature of the reaction of the isolated heart to changes in the work which it is called upon to perform. These changes in work are here brought about by variations in the venous inflow or the peripheral resistance or in both. The effect of changes in the  $CO_2$  tension in the gas ventilating the lungs, and of the addition of adrenaline to the circulating blood, will also be shown.

2. Dr. H. H. Dale will demonstrate an apparatus for artificial circulation, designed by Dr. E. H. J. Schuster and himself, and consisting of two diaphragm pumps, the throws of which are independently adjustable while the machine is in action. The two pumps are made to replace the two ventricles of the heart, so that the reactions of the blood vessels of both major and minor circulations, and the resulting changes in resistance and in distribution of the blood in the system, can be studied, free from the complications of compensatory or other changes in the action of the living heart. One pump carries out the circulation through the lungs, the other through the whole, or any selected part, of the systemic circulation. This system, with its artificial heart and natural resistances, is in some sense a counterpart of the heart-lung preparation.

3. Sir Arthur Keith will demonstrate: (a) models made in 1906 to illustrate the movements of the human heart and to explain the negative wave in the jugular pulse, and (b) Sir James Mackenzie's original polygraph preserved in the Museum of the Royal College of Surgeons. Sir Arthur Keith will also give a brief account of the anatomical examination of hearts observed and recorded by James Mackenzie during his practice in Burnley.

4. Sir Thomas Lewis will demonstrate, with the help of Dr. Ronald Grant and Dr. K. E. Harris, on Wednesday only at 11.30 a.m., some reactions of the human skin to stimulation, illustrating contraction of the minute vessels and their reactions to injury.

5. Dr. B. W. S. Mackenzie will show some of Sir James Mackenzie's original apparatus.

Some tickets are still available for these demonstrations, and medical practitioners who desire to be present should apply for them at once to the Registrar, Royal College of Physicians, Pall Mall East, S.W.1.

## LYMPHADENOMA AND RELAPSING PYREXIA.

## Dr. MacNalty's Report.

MANY interesting and instructive facts concerning this manifestation of lymphadenoma are to be found in a report entitled "An investigation of lymphadenoma with relapsing pyrexia," which has been prepared for the Ministry of Health by Dr. A. Salusbury MacNalty, medical officer to the Ministry.

Dr. MacNalty discusses the nomenclature of the disease and favours the term "lymphadenoma" for all types in which there are definite and recognizable histological changes in the lymphatic glands. Referring to Osler's classification, Dr. MacNalty regards lymphadenoma with relapsing fever as a clinical entity possessing distinctive features. He points out that the disease has long escaped recognition as a clinical entity owing to the difficulties in diagnosis before Reed established the histology of lymphadenoma in 1902; it has been given various designations, such as "pseudo-leukaemia" (infectious form) (Pel); "some morbid appearances of the glands and spleen" (Hodgkin); and "lymphosarcoma with relapsing fever" (Renvers). Gowers, Musser, and Taylor have specially drawn attention to the relapsing fever in lymphadenoma. Dr. MacNalty described thirty-two cases of the disease in the *Quarterly Journal of Medicine* in 1911, and since the publication of that paper he has obtained abundant evidence that this disease has salient and individual features which make it a distinct clinical syndrome.

The etiology is similar to that of the chronic form of lymphadenoma, and both have the same histological changes in the lymph glands. Lymphadenoma exists without any evidence of tuberculosis, and therefore it cannot be regarded as an atypical form of this infection. There is no doubt, however, that it predisposes to tuberculosis, and that it is likely to be confounded with it, as is shown by the reports of the cases in this investigation. Lymphadenoma, though it disseminates and infiltrates non-lymphatic structures such as bone, cannot be regarded as a new growth on this account, for the granulomata—syphilis, tuberculosis, and actinomycosis—behave in a similar fashion. The "Hodgkin's sarcoma" is regarded by Professor Turnbull as a "lymphosarcomatoid" type of inflammatory reaction; he goes further, and considers that lymphosarcoma is an inflammation and not a new growth, because the deposits only involve the Malpighian bodies of the spleen, and do not affect the spleen pulp. Symmers regards lymphadenoma as a transition stage between the granulomata and the new growths.

Though the cause of lymphadenoma is at present unknown the balance of evidence is in favour of it being a specific infective granuloma of protozoal origin. The facts that appear to support this hypothesis are the familial tendency; the acute course in certain cases, death occurring within six weeks; and the remarkable outbursts of fever, together with its relapsing character and the sometimes periodic enlargement of the glands. Its clinical history is analogous to certain protozoal diseases, such as malaria and relapsing fever, and the beneficial results occasionally obtained by arsenic also simulate the results obtained by this drug in protozoal infections. Osler supported this view of the disease, and suggested that it might be a spirillosis. Dr. Mervyn Gordon, however, has failed to isolate a spirochaete by using the anaerobic culture methods which have proved efficacious in the culture of *Spirochaeta pallida*. Bunting and Yates claim to have isolated a Gram-positive pleomorphic diphtheroid bacillus, but this has not been confirmed. Bacteria have also been obtained from the blood during the pyrexial periods, and the pyrexial attacks have been regarded by some observers as being a terminal infection. This cannot be true, for the disease may start acutely; the febrile attacks may last for as long as four years, and some cases pass into the chronic afebrile form of the disease. Dr. MacNalty has investigated the blood for parasites, performed splenic puncture, made repeated blood cultures, and examined the body secretions on many occasions, all with negative results.

The most common primary site is the cervical glands, but Dr. Turnbull found from *post-mortem* figures that the primary site in 40 per cent. of cases was the abdominal glands, in 30 per cent. the intrathoracic, and the cervical glands in 22 per cent. Experimental pathology has not, as yet, helped to elucidate the problem, because the disease apparently cannot be transmitted to animals. Professor Woolridge reports that dogs are liable to a symmetrical bilateral enlargement of the lymph glands, but sections of these glands have none of the histological appearances of lymphadenoma, but of lymphoma. Dr. MacNalty suggests that anthropoid apes might be suitable animals for experiment, since they have proved so useful in the investigation of syphilis.

The granulomatous nodules are found in structures other than lymphoid tissue—namely, the liver, kidneys, ureter, and pleura; they directly invade bone, and occur also in the marrow of long bones. The histology of this disease is similar to that of chronic lymphadenoma. The various stages in its histology, as previously described by Longcope, have been confirmed by examination of glands in the present series, particularly the marked fibrosis in the advanced stages and the cellular composition of the glands in the earliest stages. In fact, it was possible to recognize some correlation between the histology and the duration of the disease.

Dr. MacNalty finds that the disease is most common in youth and early adult life, the commonest age incidence being 20-30. The symptomatology is well described, interesting features being the symptoms produced by intrathoracic deposits and the various abdominal manifestations described by Rolleston. In its onset the disease is usually insidious, and it has been mistaken for influenza or early pulmonary tuberculosis; it may, however, commence with the development of sudden respiratory symptoms. The disease may be superimposed on chronic lymphadenoma, as in one case reported.

From a careful analysis of the salient features of the many previously reported cases and the author's seventeen cases Dr. MacNalty has classified the disease into two main types: (1) a form with enlargement of the external glands, with or without involvement of the internal glands; (2) a form in which the internal glands are alone involved. The first type is further subdivided into two groups, one with slight or no enlargement of the glands during the periods of pyrexia, and another group in which the clinical picture alters suddenly during the attacks of pyrexia, the glands becoming much enlarged, tender, hot, and painful, with adherence and reddening of the skin. The second group is uncommon, and very closely resembles acute suppurative lymphadenitis. The various types may occur as intermediate or mixed forms.

Dr. MacNalty has drawn an accurate, clear-cut, clinical picture of this disease, and among many other interesting peculiarities he points out that excessive appetite is often a prominent feature. The prognosis is very unfavourable, particularly in the second type—namely, that with internal glandular involvement alone. X rays do not have any permanent curative effect in this disease, but arsenic is undoubtedly beneficial in many cases; Fowler's solution is said to be better than intravenous forms of arsenic, such as salvarsan and neosalvarsan. Difficulties in differential diagnosis are greatest in this second type, for in type 1 excision and microscopy of a superficial gland will settle the nature of the condition. This histological examination should always be performed when a superficial gland is available. Chronic pulmonary tuberculosis and chronic tuberculous adenitis with relapsing fever are most likely to be confused with the disease, and a diagnosis can often only be made by consideration of the clinical features and by a process of elimination. The author discusses the differential diagnosis very fully, and this part of the report should prove very useful to the clinician. The recognition of this disease is not of mere academic interest, but it is important from the point of view of prognosis and its separation from other diseases.

Dr. MacNalty has performed a very useful service to clinical medicine. From the admittedly ill-assorted group of diseases characterized by enlargement of the lymphatic glands he has separated one clinical type, distinct in its

morbid histology, sufficiently unlike other diseases in its clinical manifestations, and unhalting in its forward march. As already indicated, it is important to recognize this disease because of its particularly unfavourable prognosis. It may be added also that the best hope for the discovery of some effective remedy lies in the accurate definition and study of this infection.

## England and Wales.

### Clean Milk Production.

ANOTHER "social evening" took place at the Royal Society of Medicine on May 7th, when Sir James Berry, the President, and Lady Berry received a very large number of Fellows and guests. During the evening an illustrated address was given by Mr. P. B. Tustin, who has been associated for many years with the campaign for clean milk, on the processes of milk production and distribution. He gave an expert account of the breeding of cows for milk-producing purposes, and the economics of the dairy farm. Discussing the mechanical milker, worked by a vacuum pump, he said that this was a very good and efficient arrangement, provided only that an intelligent man was in charge; otherwise, used carelessly, it was liable itself to be a source of contamination. He insisted that the production of clean milk was a matter of method rather than of expensive equipment, and he described an experiment which showed that even in an extremely insanitary barn—not that such places were to be tolerated—clean milk could be produced, given proper methods in the handling of the cow and the taking of due precautions. The equipment necessary for clean milk production included curry-comb, brush, and clippers, and a bucket of water. The milk should be received in a small-top pail, the milker should thoroughly wash his hands before beginning his job, the stool on which he sat, and the position of which he had often to adjust with his hand, should be clean, and, given these conditions, with fastidiousness as to the cow's udders, all contamination in the milking process should be avoided. Mr. Tustin said that the dairy farmer had made enormous strides in clean milk production during the last few years. Such cleanliness had been very largely stimulated by clean milk competitions, of which there was only one in this country in 1919, while there were fifty-eight, in different counties, last year. Mr. Tustin described the method of pasteurization and the clarifying and other equipment of the modern milk factory. In milk consumption per head of population, he said, the British people were unaccountably backward as compared with the Scandinavian nations, and even with America and Canada. He also dwelt upon the really extraordinary organization whereby milk produced one day in Somerset or somewhere else, on the next day finds its way, pasteurized, bottled, and sealed, on to the London doorstep—an achievement at least as expeditious, he claimed, as anything that the post office can show in the way of delivery, and relatively cheaper. In proposing a vote of thanks to the lecturer, Dr. Andrew Balfour said that he noticed that Mr. Tustin had not touched on the sophistication of milk. This was no longer an important problem, perhaps, in this country, but in tropical countries it was very much a matter of concern, and he recalled how a hospital in Mauritius once received its milk with small fish swimming about therein! The fish, which had been used for the destruction of mosquito larvae, had been scooped up in the water so profusely added to the milk.

### Leicester Royal Infirmary.

The report of the Leicester Royal Infirmary and Children's Hospital for 1927 records a further increase in the demands made upon that institution, and it is therefore pleasing to note that the financial position is satisfactory and that the governing body has enough confidence in the outlook to undertake provision for future needs. Admissions during the year numbered 6,788 against 6,485 in 1926, and the number of out-patient attendances was 151,281 against 146,733 in 1926. A point of some interest, in view of the keen discussion now current regarding the future of the hospital services, is that of the in-patients

treated approximately 60 per cent. were insured persons and members of approved societies. The proportion would, of course, be considerably higher if patients of 16 years and under and 65 years and above were excluded, as such patients are not within the scope of the national insurance scheme. From the total income of £78,009 the board was able to meet the ordinary expenditure, provide for several substantial items of extraordinary expenditure, and wipe off part of the accumulated deficit of previous years. Ordinary expenditure, at £69,679, was £1,557 below the 1926 figure, in spite of the fact that the work done was on a more extensive scale. Extensions in progress include a temporary ward of thirty beds, two new wards of fifteen beds attached to the orthopaedic department, two new operating theatres, and the reconstruction of the kitchens, the estimated cost being £31,000. On July 1st it is intended to begin the reconstruction of the central wing, which will provide three wards in place of two, at an estimated cost of £50,000, making a total of £81,000. Mr. H. T. Mills of Langton Hall has undertaken to contribute one-third of the cost, up to £20,000, of the central wing reconstruction, and other donations amounting to £22,863 have been received.

#### Women Medical Students and London Hospitals.

A conference attended by about two hundred representative women was held under the auspices of the National Union of Societies for Equal Citizenship on May 8th to consider the question, in the light of recent events, of women in the service of hospitals. The speakers included Dr. Graham Little, M.P., Miss Eleanor Rathbone, president of the union, Dr. Margaret Emslie, and others. Several resolutions were carried, the principal one protesting against the exclusion of women medical students from all the London general hospitals with training schools (with the exception of the Royal Free Hospital and, for a limited number of vacancies, University College Hospital). Dr. Graham Little said that there was no sufficient provision at the present moment for the teaching of women medical undergraduates in London. There were large fields of medicine, left untillied by men, which ought to be taken up by women, and he foresaw an enormous possible expansion of medical work in this respect. Even if one wanted to do so, he could not stay the entry of women into medicine, and therefore the wise course was to secure the professional education of women in the best possible way. If the material and facilities for women medical students in London—the best centre in the world for the purpose—were inadequate the result would simply be to take women to the provinces, where no such fantastic position existed. Miss Eleanor Rathbone laid stress upon the fact that the hospitals were supported by women as well as by men, and that they depended to an increasing degree upon funds to which women, as well as men, were asked to contribute, either through collections or deductions from wages. An attempt was now being made to establish a male monopoly, and women subscribers to hospitals were virtually being compelled to exclude their sex from the training which what were improperly called “men’s” hospitals—though the patients included women as well as men—afforded. It was agreed to ask the National Union to organize a representative committee to bring this point of view before the hospitals and appropriate public bodies, also to call upon local authorities and voluntary bodies responsible for the administration of hospitals to ensure the appointment of women on the responsible committees, and to give equal opportunity in training facilities. A further resolution urged that visiting committees of mental hospitals should be required to co-opt at least two women in cases in which women had not been otherwise appointed, and drew attention to the need for the appointment of women doctors in all mental hospitals, with opportunities to rise to the highest posts.

#### L.C.C. Medical Officers.

The Minister of Health has asked the London County Council to allow its medical officer of health, Dr. F. N. K. Menzies, to serve on the departmental committee to investigate the present situation in regard to the training and employment of midwives, as he feels that Dr. Menzies’s

knowledge of the subject and interest in questions affecting maternal welfare would be of considerable assistance in the inquiry. Dr. Menzies, however, is at present absent from duty owing to ill health, and has been granted sick leave until the end of June. The council has agreed to Dr. Menzies serving on the committee, subject to his state of health on his return to duty allowing him to do so. The council has agreed that one of its assistant medical officers, Dr. Naney Holloway, shall exchange duties for a period of one year with a school medical officer, Dr. Eleanor Stang, attached to the health department of Western Australia. Each officer will continue to receive her own salary from the authority at present responsible for its payment, and any adjustments are left to be made privately.

## Scotland.

#### Hospital Problems in the Highlands.

A CONFERENCE convened by the Scottish Board of Health to assist the movement for hospital co-operation was held this week in the Town Hall, Inverness, under the chairmanship of Dr. W. E. Elliot, Under Secretary of State for Scotland. In a letter sent to the voluntary hospitals and public authorities in the counties of Inverness, Moray, Nairn, Ross and Cromarty, Caithness, Sutherland, and Orkney, representatives were desired to discuss some of the immediate questions arising in connexion with the Northern Infirmary at Inverness. It was considered desirable that the directors of this institution, now under construction, should know what will be its relation to other voluntary hospitals in the north, and particularly what accommodation and services it will be expected to provide in connexion with services administered by the public authorities for tuberculosis, maternity, children’s diseases, and venereal diseases. Following the recommendation of the Mackenzie Committee on hospital services, the Northern Infirmary is being equipped as a central hospital for the northern region. A sum of £60,000 out of the £100,000 required to give effect to this recommendation has been already raised, and building operations have commenced. It was arranged that Dr. Elliot should lay the foundation stone of the infirmary on May 8th, and that on May 10th he should perform the opening ceremonies at the extended sanatorium which is managed by the British Red Cross Society at Stornoway, and at the extension of the Lewis General Hospital at the same place. The two latter functions formed an important landmark in the history of hospital organization in the Outer Hebrides. The Lewis Hospital is an experiment in State medicine in a remote part of Britain which will be watched with interest for the influence it may have upon developments further south. The large island of Lewis has a population of over 32,000, and until very recent times medical practice was possible only on a limited scale, mainly on account of difficulties of transit, so that the practices of earlier generations in the shape of hereditary healers and village bone-setters still persist. The hospital scheme inaugurated by the Scottish Board of Health has now gained the confidence of the people. The original hospital, erected by public subscription in 1896, was enlarged in 1912 to provide twenty beds. Owing to local prejudice it was not fully used until 1924, when a specialist surgeon was appointed in Stornoway by the Board. The new hospital will contain twenty-four beds and four cots, and has been equipped with x-ray plant, an operating theatre, a laboratory, and all the other requisites of a modern hospital. It also contains a private ward. Cases requiring special surgical treatment which are not urgent are referred to hospitals on the mainland. The scheme of providing specialist services has now been in operation since 1926, and already great demands have been made upon the hospital, where still further extension will probably, it is thought, soon be required. The Board of Health will not contribute towards maintenance, so this charge will have to be met by local contributions and payments. The nursing service, controlled by local committees, is subsidized by the Board of Health, and it is expected that a much extended district nursing scheme will shortly be instituted.

**Summer Post-Graduate Courses in Glasgow.**

The Glasgow Post-Graduate Medical Association has completed its arrangements for post-graduate teaching in that city during the coming summer, from June to October. The instruction is offered in three forms—a general medical and surgical course, certain special clinical courses, and clinical assistantships. The general course will occupy four weeks, from August 20th to September 15th, and has been designed to include most of the subjects likely to interest general practitioners. Throughout this period the mornings will be devoted to general medical and surgical diagnosis and minor surgery, in the Royal and Victoria Infirmarys, while special subjects will be taken at various appropriate centres in the afternoons. Demonstrations in psychological medicine will be given on the four Saturday mornings at Duke Street Hospital and at Gartnavel Mental Hospital. The subjects covered in the special clinical courses, intended for general practitioners who have not much time to give to hospital work, include surgery, obstetrics, gynaecology, dermatology, radiology, venereal diseases, diseases of children, and diseases of the ear, nose, and throat. At most of the institutions taking part in the work of the association a limited number of clinical assistantships are available during the summer months as well as at other times of the year. These appointments afford exceptional opportunities for special study, and graduates securing them are expected to enrol for three months. Copies of the syllabus may be obtained from the secretary (Dr. James Carslaw), Post-Graduate Medical Association, The University, Glasgow.

**East Fortune Sanatorium.**

With regard to the annual report by the medical superintendent of the East Fortune Sanatorium summarized in the *British Medical Journal* for April 28th (p. 728), it should be explained that the figures published respecting results of treatment referred to the number of days spent in the sanatorium by patients ultimately discharged in various conditions. Thus of the male patients treated for diseases of the lungs and chest glands, those whose cases were clinically quiescent on discharge had remained under treatment for 227 days, much improved 204 days, improved 251, stationary 41, worse 372, while those who died had on the average been treated for 282 days. The corresponding figures for women were: 181 days clinically quiescent, 227 much improved, 226 improved, 118 stationary, 489 worse, and 92 days for those who had died. Of the children, those who were discharged clinically quiescent had remained in the sanatorium on an average 205 days, much improved 393 days, and there had been no deaths among children. The total number of deaths was 29.

**Ireland.****McKisack Memorial Fund.**

A MEETING of the subscribers to the McKisack memorial fund (announced in our issue of April 21st, p. 686) will be held in the Royal Victoria Hospital, Belfast, on May 17th, at 10.30 a.m., immediately before the clinical meeting of the North of Ireland Branch of the British Medical Association. All those who intend to join are asked to forward their subscriptions before that date so that the accounts may be closed. They may be sent to Dr. W. Caldwell, 56, Wellington Park, Belfast, or to any other member of the committee.

**The Need for Hospital Co-ordination.**

Senator Sir Edward Coey Bigger, M.D., speaking as chairman at the annual meeting of the Monkstown Hospital, said that before referring to the position of the hospital and its need for greater financial assistance, he would like to mention two points connected with the question of hospitals and hospital treatment in the country. The first was that, although they had some of the most highly skilled physicians, surgeons, and specialists in the world, who gave their services most freely and

whole-heartedly, in the large voluntary hospitals, they were not employed to the extent that they should be or to the best advantage. More co-ordination was required between the small and the large hospitals. Many patients were admitted to the small hospitals who needed the most skilful diagnosis and treatment; by sending them to the larger clinical hospitals, with their special equipment and complete organization for laboratory work, x-ray and radium therapy, and diagnostic investigation, patients would receive the advantage of the best available advice and treatment. This could be carried out under the Public Health Acts by co-operation between the local health authority and the large voluntary hospitals. The hospitals would, of course, recover the cost of treatment from the health authority. Such co-ordination would be of the greatest benefit to the patients, to the hospitals, to medical science, and to the training of students and nurses. The other point that he wished to make was that the State provided a medical service for those who were unable to pay for treatment, but there was a large class above those who could claim free treatment who could not, on account of their limited means, pay the usual medical fees—either for prolonged illnesses or difficult operations or even special diagnoses—for whom something might be done. There had been a great change in the position of hospitals during recent years. The development of hospital treatment as against home treatment was constantly increasing; the difficulty and expense of modern methods of treatment, combined with the dependence of those methods on skilled nursing, had made it practically impossible for them to be carried out at home. He mentioned these points in the hope that they might receive serious consideration. Proceeding, Sir Edward said that Monkstown Hospital had done most useful work, and it was surprising that so many cases should have been treated in such a small hospital. The remarks that he had just made about small outlying hospitals in the country did not apply to the Monkstown Hospital, which had a very large staff of honorary and consulting physicians and surgeons. He had referred to small hospitals with, perhaps, one medical officer and, possibly, forty or fifty beds. He was glad to see that in Monkstown Hospital wards were provided for people with limited means. In the financial part of the report there was one item which greatly pleased him—that was the provision for nurses' pensions. The money spent in Monkstown Hospital had been well spent; such a hospital was a tremendous asset to the district. He hoped everyone would realize his responsibility in regard to it.

**Vaccination Bill in the Dail.**

A resolution recently adopted by the executive committee of the Irish Medical Committee with regard to the Vaccination Bill now before the Dail states that the executive committee has learned with anxiety of the proposal to permit exemption from compulsory vaccination on the plea of conscientious objection. In the opinion of the committee any tampering with the compulsory action of the vaccination laws would be likely to render the laws nugatory, and to expose the population of the Irish Free State to the grave danger of an epidemic of small-pox. The danger was all the greater because of small-pox now being rife in England, a condition which had been brought about by the very step which it was now proposed to take in the Irish Free State.

**Education of Mentally Defective Children.**

At the meeting of the Belfast City Council held on May 1st the School Medical Services Subcommittee of the Belfast Education Committee recommended that the principal committee should draw the attention of the Ministry of Education to the necessity for the establishment in Northern Ireland of an institution where mentally defective children, ordinarily resident in Northern Ireland, might be educated.

**A Medical Officer's Resignation.**

At the same meeting of the Belfast Corporation attention was drawn to the resignation of Dr. R. McCulloch as assistant medical officer for tuberculosis. The chairman of the Tuberculosis Committee said that Dr. McCulloch could not

see his way to comply with a provision that he should record his time at the institute by means of the "clock" instead of by entering his signature in a book. The regulation had been approved by the corporation, and other members of the institute staff had complied with it. There had been discussion about it, and opinion was divided. The resignation was accepted.

### CYCLICAL VOMITING AND APPENDICITIS.

SIR,—Cases of cyclical vomiting in children frequently develop symptoms suggestive of acute appendicitis. There is danger of hurried resort to operation with the great risk attending upon general anaesthesia in the presence of acidosis.

A simple test can be used which will often decide for or against operation. Having observed the relief of distress and the relaxed condition of the patient's limbs and abdominal wall following an attack of vomiting in a severe case of cyclical vomiting some years ago, I used emesis, produced by giving the same child two tumblers of water to drink, in a subsequent attack accompanied by fever, with pain and rigidity in the right iliac region. The child vomited promptly, and at once the resistance over the appendix was felt to have disappeared. The child died soon after operation for appendicitis, performed a few months later during my absence from town.

Shortly afterwards another severely ill patient was saved from operation through the use of the same manoeuvre, and made a good subsequent recovery on strict diet with alkalis. During the last week one of my students used the emesis test on a case sent into the Kingston General Hospital for immediate operation, with a similar result. A full clinical examination revealed the acidosis and the true condition.

I have not met with any mention of this method of diagnosing the presence or absence of appendicitis in this class of case, and apparently it is unknown to many. It seems worth while recording, so that full trial may be made of it. It may be well to remember that in these days of safe and successful surgery there are conditions where the necessary anaesthesia may lead to death.—I am, etc.,

THOMAS GINSON,

Professor of Pharmacology and Therapeutics,  
Queen's University, Kingston, Ont.

April 23rd.

### DEAD AND INFECTED TEETH.

SIR,—In your issue of April 28th (p. 731) Mr. C. Jennings Marshall very rightly draws attention to the importance of Mr. A. P. Bertwistle's article on dead and infected teeth (April 7th, p. 589). In his desire to emphasize this he closes with the rather sweeping statement, "The stopping of teeth in which the pulp cavity has been infected is a surgical heresy, and I would like to put forward the suggestion that it is the duty of the medical profession to discountenance the procedure."

May I be allowed, for a definite reason, to repeat very briefly one or two of the facts having a bearing on the opposite side of the question?

"Teeth in which the pulp cavity has been infected" must include not only those in which the pulp has died from infection, not only those in which the pulp has been killed by the dentist owing to its involvement in the carious process and inevitable infection, but also, according to recent bacteriological work in America, a considerable proportion of filled teeth in which the pulp still reacts, although sluggishly, to the ordinary vitality tests, which produce no local signs or symptoms whatsoever, but which have been proved in a certain number of cases to have caused rheumatoid conditions that have cleared up on removal of the degenerating pulp and its replacement by a properly inserted filling. Mr. Jennings Marshall must therefore be prepared to recommend the extraction of all dead and a proportion of living filled teeth.

There is an old observation on this subject which will

bear repetition, to the effect that the doctor examines the mouths of a small proportion of the population, mostly sick; the dentist those of a large proportion of the population, mostly in good health. Why should the former, on the strength of what he sees, condemn the dentist to a policy of wholesale extraction, the effects of which, in mutilated mouths, spacing of the teeth and consequent interstitial caries, traumatic occlusion and consequent pyorrhoea, faulty mastication and consequent chronic indigestion, he is unlikely to see or realize?

In America, where the importance of Hunter's teaching was admitted and acted on more quickly and more wholeheartedly than in more conservative Britain, a policy of 100 per cent. extraction of dead teeth was the almost immediate result. A careful study of the dental literature of recent months clearly points to a gradual but progressive return to a middle course based on more careful selection of cases for root canal work, and in face of the brilliant and devastating bacteriological studies of Rosenow, and the voluminous, if less convincing, work of Weston Price. In the *Journal of the American Dental Association* for January, 1928, Coolidge reports a series of 147 carefully selected cases for root canal filling, showing 3 per cent. failures, 19 per cent. where there was still a slight element of doubt as to the ultimate success, and the remaining 78 per cent. undoubtedly successful.

In advancing these points I have no wish to belittle the dangers of infected teeth, and until a solution of the problem has been found these dangers cannot possibly be over-emphasized; but a policy of 100 per cent. extraction is a policy of despair which, recommended blindly by the medical profession, can only retard and impede progress towards that refinement of diagnosis in the choice of suitable cases for conservative treatment, and that development of technique in root canal therapy, which provide the only real way out of the present position.—I am, etc.,

Brussels, May 1st.

T. DUNCAN GOULD.

### INHERITANCE OF MENTAL DEFECT.

SIR,—Any editorial pronouncement in the *British Medical Journal* of necessity carries such weight that I am tempted to invite your attention to the annotation in your issue of April 21st (p. 680) on sterilization of the feeble-minded in Alberta, where this sentence occurs: "Scarcely any fact is more securely established than that it is only a small, almost negligible, minority of mentally defective persons who are the offspring of parents themselves certainly mentally defective." On the other hand, I read in a paper on heredity of feeble-mindedness by H. H. Goddard, Vineland, N.J. (reprinted from the *Eugenics Review*, April, 1911), with regard to one single family, "Since this was written this family has been further investigated, with the result that we now know the facts concerning 319 members, of whom 119 are feeble-minded, with only 42 known to be normal." Can you assist me in reconciling the two statements?—I am, etc.,

Bristol, April 30th.

D. S. DAVIES, M.D.

\*\* The two statements to which Dr. Davies directs attention are not contradictory. It is true that where both parents are mentally defective the offspring are almost certainly mentally defective also, and that even where one parent only is mentally defective, some of the offspring are likely to show the same characteristics. Nevertheless, it is true also that in any generation only a small proportion of mental defectives are the children of parents who themselves are certainly mentally defective, the overwhelmingly larger proportion being the children of apparently normal parents, of "carriers" who themselves are normal, or of those who suffer from mental or nervous instability or from psychoneuroses or a mild degree of mental abnormality not certifiable. It follows that, for the purpose of cradling or preventing the spread of mental deficiency, the sterilization of a small number of feeble-minded persons would be ineffective. Attention may be again directed to the pamphlet on *Sterilization and Mental Deficiency* published by the Central Association for Mental Welfare.

## ERYTHEMA NODOSUM AND TUBERCULOSIS.

SIR,—Dr. W. Camac Wilkinson, in his article entitled "The affinities between rheumatism and tuberculosis" in your issue of May 5th (p. 749), makes particular reference to the association of erythema nodosum with tuberculosis. He goes so far as to say, "... I have not once seen erythema nodosum apart from tuberculosis." That the association of the two conditions is a very close one is evident from the fact that, from a clinical standpoint, it can be demonstrated in fully 20 per cent. of cases of erythema nodosum, if a careful physical examination is made, and if the after-history is followed up. I reported a series of such cases in the *British Medical Journal* of April 25th, 1914 (p. 909), and in a book, which is at present in the press, I have added reports of many others.

It does not necessarily follow from this that erythema nodosum is a tuberculous disease; indeed, in the great majority of cases even the use of tuberculin has failed to prove this—a failure resulting possibly, as Dr. Wilkinson remarks, not from the tuberculin, but from the administrator. He says that histologically the lesions of erythema nodosum cannot be distinguished from rheumatic lesions of the skin. Personally I have no knowledge of the histology of rheumatic skin lesions, but I have on several occasions excised erythematous nodes, and the histology of mature nodes is identical with that of tuberculosis in epithelioid and giant cells.

My own view is that erythema nodosum is a specific fever which leaves the patient unduly susceptible to tuberculosis. Whatever the explanation may be, however, Dr. Wilkinson has served a most useful purpose in drawing attention to the association of the two conditions, for many lives are wrecked or sacrificed by failure to take precautions after erythema nodosum, a disease which is still generally regarded by the profession in this country as a mild cutaneous disorder demanding little or no attention.—I am, etc.,

Clifton, Bristol, May 5th.

J. O. SYMES.

## THROMBO-PHLEBITIS MIGRANS.

SIR,—The subject of thrombo-phlebitis migrans, discussed in your issue of April 7th (p. 586) by Professor T. Gillman Moorhead and Dr. Leonard Abrahamson, and continued in your issue of April 21st (p. 690) by Dr. Owen, has interested me very much, as lately I have had five cases of this condition.

In Professor Moorhead's article the authors stress the conspicuous absence of embolic symptoms, in spite of their patients' habits being most favourable to an embolus. They note subacute occurrences, and have been at pains to show that the blood cultures were sterile; they state also that the various treatments used had no apparent effect on the course of the disease. Of the four cases quoted in this article, one patient had had a previous illness, one had an injury, and two were persons of middle age who were apparently in robust health.

In Dr. Owen's communication this condition is recognized as occurring in the presence of an influenza epidemic, in proximity to operations, and in confinements. It would therefore appear that there is no specific relationship between this condition and micro-organisms, but it must be primarily regarded as resulting from the general state of the patient, who is affected later by some infection or chemical changes which temporarily lower the general resistance.

There is one factor common to all these conditions, and that is the state of the soil (that is, the patient), which when exposed to a further strain, as by an infection or an anaesthetic, evinces one common result manifested by thrombo-phlebitis. The changes which lead up to the result—namely, a thrombosis—are obviously primarily concerned with the state of the blood, and that is the one common cause; and I submit that the true explanation is arrived at by the work of Mr. J. E. R. McDonagh, and plainly put forward in volume 2 of *The Nature of Disease* (p. 289) and in an article by him in the *Lancet* of April 16th, 1927 (p. 845), in which thrombo-phlebitis migrans is fully discussed.

The state of the blood being the real cause of the manifestation of a thrombo-phlebitis explains at once how it is

that the original thrombus occurs—which may be in a superficial vein in a limb where it is evident, a deep vein in a limb where it gives rise to physical signs as in enteric fever, or in a viscus where it is seen *post mortem* as an infarct—and that thromboses may be multiple and recurring, thus giving rise to the condition of so-called thrombo-phlebitis "migrans." As long as the blood remains in the condition of dehydration and liable to gelation, so long are thromboses likely to occur, and do so in any part of the body. That the condition in the lungs should be caused by a detachment of a clot from a vein lodging in a branch of the pulmonary artery is ruled out by the fact that the affected area in the lungs does not always correspond with the area supplied by one vessel, and, moreover, that in some cases where the affection is widespread, involving the whole of an upper lobe, the embolus would have to be of a very considerable size, and, furthermore, thrombosis here may be primary.

The treatment in all my cases has been the same as that carried out and described by Mr. McDonagh in his article in the *Lancet*, and has been successful in all. In some cases I have noticed that after the first injection of sup 36 there has been some pain locally at the site of the thrombus in vessels in the leg.

It is only natural that in an influenza epidemic, where a large number of patients are affected, some of those would be in such a primary condition as to develop a thrombosis owing to the superadded infection. In post-operation cases it is due to the anaesthetic, and in pregnancy it is most likely to occur in women who have albumin in the urine, and who are in a debilitated condition and affected by oral sepsis.

The points I wish to emphasize are that this condition is not due to any specific organism, and, as such, cannot be regarded as primarily a bacterial infection; that it is encountered as a sequel to various diseases and injuries; that it depends more on the condition of the patient than on any other factor; and that the idea that subsequent thromboses are due to the detachment of emboli cannot be any longer seriously considered.—I am, etc.,

Docking, Norfolk, April 26th.

W. W. JEUDEWINE, M.D.

## EFFICACY OF TUBERCULIN.

SIR,—The views expressed about tuberculin are somewhat opposed, but can be summarized as follows: (1) It is dangerous. (2) It is useless or no better than ordinary treatment. (3) It is useful, but especially so if some particular preparation is employed. (4) That those who practise tuberculin do not employ "controls," and, therefore, they cannot gauge the value of their treatment as compared with other methods.

(1) Tuberculin is certainly dangerous if used in unsuitable cases and in the wrong doses. Dr. Crofton (April 7th, p. 611) rightly says: "It is easy to kill any patient with strychnine, it is easy to kill a tuberculous patient with overdoses of tuberculin; but no physician kills patients with strychnine, and no patient is killed by tuberculin given in proper doses." In my opinion no one should attempt the tuberculin treatment of advanced cases of tuberculosis without first undergoing a course of instruction at an institution where tuberculin is systematically given.

(2) I went to Dr. Camac Wilkinson's clinic as an absolute sceptic some six years ago, but gradually became convinced that in his hands, at any rate, tuberculin is the remedy *par excellence* for tuberculosis. What struck me was that, without any medicines, the general health of the patients seemed to be better than that of those treated on ordinary lines. I was so impressed that I started a tuberculin clinic in my own hospital, which I have carried on ever since. I have had excellent results in early tuberculosis and asthma. In open tuberculosis I can only describe my results as "fair."

(3) With regard to the special value of particular preparations I cannot speak much from personal experience, but all tuberculins appear to act in the same way. This is confirmed by the phenomena of the tuberculin reaction, which are similar whatever tuberculin is used, the only difference being in the degree of the reaction, which varies with the toxicity of the preparation. It seems to me,

therefore, that a knowledge of *when* to use it and *how* to use it is more important than the selection of a particular antigen.

(4) It is more difficult to make a comparison between cases treated by tuberculin and by ordinary methods than would be supposed. Attempts have been made to compare the mortality amongst those who have had tuberculin and those who have not. In order to convince the non-believer in tuberculin, statistics have been chiefly confined to the cases with tubercle bacilli in the sputum. Now tuberculin, to be of real service, should be used in the early stages before the bacilli have appeared in the sputum. Even in the later stages, however, it would appear from the comparatively few cases that have been recorded that life can be prolonged by tuberculin in a certain percentage of cases. In the earlier stages the diagnosis cannot be made with certainty without the use of tuberculin and skiagraphy. If the former shows hypersensitiveness and the latter indicates activity the condition is certainly tuberculous. Even if there are no radiographic changes and no abnormal physical signs, and yet there are symptoms of early tuberculosis, the physician who uses tuberculin will be on his guard if he gets a strong positive reaction with it. He will not necessarily treat such a patient with tuberculin, but if that patient is not progressing favourably under ordinary methods he certainly will do so. To produce statistics which will convince the unbeliever is, however, difficult, for he cuts the ground from under one's feet by saying, "Everyone reacts to tuberculin," which is, of course, a half truth, and depends on what is meant by a tuberculin reaction. The comparison with "controls" is not so easy as it sounds.

In my hands I find:

1. That children thrive on tuberculin.
2. That in adults (provided they are afebrile and there are no tubercle bacilli in the sputum) the more sensitive they are to tuberculin the better are the results.
3. That cases exhibiting much fibrosis do not benefit greatly.
4. That in tuberculous asthma it acts almost as a specific.
5. That in open tuberculosis it is wisest to send the patient to a sanatorium till the condition has become stabilized, but, on his return, it is well to keep up his general health by means of cautiously administered tuberculin.

—I am, etc.,

London, E.C., April 20th.

F. E. GUNTER, M.D.

#### MEDICAL AUTOGRAPHS.

SIR,—I am endeavouring to compile a list of medical societies or institutions that possess a collection of medical autographs, my purpose being to encourage this method of perpetuating the memory of those pioneers of medicine who have for the most part passed beyond the Veil, but whose names live as the benefactors of mankind.

The extensive collections that are possessed by the Royal College of Physicians, the Royal College of Surgeons, the Royal Society of Medicine, and that more recently acquired by the British Medical Association, are familiar to me, but there must be many other professional societies both at home and abroad that have recognized the historical interest of such literary memorials, especially when associated with an album of portraits. I shall be grateful if such societies will furnish me with some particulars of any collections they possess.—I am, etc.,

Hinton Firs, 15, Gervis Road,  
Bournemouth, May 3rd.

JAMESON B. HURRY.

#### The Services.

##### ROYAL NAVAL VOLUNTEER RESERVE.

THE KING has approved the award of the Royal Naval Volunteer Reserve Officers' Decoration to Surgeon Commander T. B. Dixon, M.S.

##### DEATHS IN THE SERVICES.

Lieut.-Colonel William Mawer James, R.A.M.C.(ret.), died at Ottawa on January 31st, aged 79. He was born in Jersey on August 14th, 1848, and took the Edinburgh double qualification in 1873. Entering the army as surgeon on September 30th, 1875, he became surgeon lieutenant-colonel after twenty years' service, and retired on February 3rd, 1897. After retirement he was employed successively at Beverley in 1897, at Hythe from 1898 to 1908, and at Guildford in 1908-09.

#### Obituary.

##### THOMAS VILLIERS CROSBY, M.D.,

Consulting Physician, Leicester Royal Infirmary.

We regret to record the death of Dr. Thomas Villiers Crosby, honorary consulting physician to the Leicester Royal Infirmary, who died at Leicester on April 26th, after a prolonged illness.

He was a son of the late Mr. James Crosby of Burlescombe, in East Devon, and was a pupil at Blundell's School, Tiverton. He received his medical education at University College Hospital, London, and graduated M.B.Lond. in 1894, proceeding M.D. in 1903. After holding for a short time a resident appointment at University College Hospital he commenced practice in Leicester. His connexion with the Leicester Royal Infirmary began in 1902, when he was appointed honorary assistant physician; he subsequently became honorary physician, and was still attached to the infirmary in a consultative capacity at the time of his death. In 1908, on the organization of the Territorial Force, he received a commission as major in the Royal Army Medical Corps, being appointed to the 5th Northern General Hospital, with which he served throughout the late war. At one time he held office as president of the Leicester Medical Society. His main interest was always in his profession, but in the years before the war he served for a period as a member of the Leicester Board of Guardians, and he was also associated with the Masonic organization as an office bearer. Dr. Crosby is survived by his widow and by two sons, one of whom, Dr. G. J. V. Crosby, is in practice at Bushby, Leicestershire.

A colleague, "A. V. C." writes: The long and sad illness of T. V. Crosby has been a source of sincere regret to his many medical confreres in Leicester, and his death came as something of a relief in that he had been spared further suffering. It was a sad chain of events. He was for years a very successful practitioner and, thoroughly weary, he retired at Christmas, 1926, hoping to enjoy a well-earned rest. In the course of a few weeks he became aware of a serious malady affecting him; with his medical friends he discussed critically the probabilities of any relief from an operation. He underwent it, however, only to learn that any radical treatment was impossible, and he obtained very little relief. His bearing in that illness was characteristic of the man; he maintained his imperturbability, so prominent during his active professional life, with its many anxieties and difficulties, even when he himself was the victim of circumstance. For more than twenty years he was an honorary physician to the Leicester Royal Infirmary, a loyal colleague, and a conscientious worker. He was always ready to give a helping hand to others, and always perfectly willing to assist in anything which might help in the smooth running of the medical wards. His kindly disposition endeared him to everyone. He had many friends, enjoyed being in company, and was fond of sport, but in recent years his work monopolized his whole time and he found little chance of recreation. Country bred, he lived his active life in a large town, but his tastes were simple; he cared nothing for show, and his sympathies were broad. Such characters are the most laudable members of our profession, and the memory of T. V. Crosby will be cherished alike by patients and colleagues.

##### THE LATE DR. JAMES WHEATLEY.

DR. CHARLES PORTER writes from Johannesburg:

"May I be permitted a word of sincere appreciation of my old friend James Wheatley, the announcement of whose passing, though I knew recently that he was ailing, was quite unexpected. I first met him on my transfer from East Kent to Stockport early in 1892 (some thirty-six years ago), and frequently thereafter at the excellent and pleasant meetings in Manchester of the North-Western Branch of Medical Officers of Health Society; and we also foregathered annually at various congresses. Wheatley's charming personality and characteristic modesty were very engaging, whilst his fairness of outlook and sound judgement made discussion with him a very helpful privilege.

When, in 1902, I resigned the post of county M.O.H., Shropshire, to come out here as M.O.H., Johannesburg, I could think of no one better suited in every way for the Shropshire appointment than he; and it was a source of particular pleasure when he applied and was selected for it. For "those who cross the sea" the attenuation of old interests and valued friendships, even with men such as Delépine, Wheatley, Niven, and many others, is inevitable, but keenly regrettable; regular correspondence soon flickers and dies. But in 1926 (just after my retirement as M.O.H., Johannesburg) Wheatley wrote me, at considerable length, from his pleasant garden in Shrewsbury, a very interesting letter about his work in and plans for the county, and his contemplated withdrawal before long from active official life; but, characteristically, he said little about himself, and I did not then gather that he was failing. My hope of meeting him again in that Shrewsbury garden is gone; but one is indeed glad that he lived to enjoy the well-earned recognition by his confreres of the excellence of his life's work, and the expression of their high personal esteem, when they honoured him by election as president of the Society of Medical Officers of Health, an honour he was destined to enjoy for all too brief a time.

Dr. SANGER BROWN, whose death at the age of 76 is reported as having occurred at Chicago on April 1st, was a well-known neurologist. He was from 1892 to 1897 professor of medical jurisprudence and hygiene in Rush Medical College, Chicago, and was also professor of clinical neurology in the College of Physicians and Surgeons, Chicago. We are indebted to Sir EDWARD SHARPEY-SCHAFER for the following details. Dr. Brown came to London as a young man and worked with me in 1886-87 in the University College laboratory on sensory localizations in the brain of the monkey. Our joint work was published in the *Philosophical Transactions*, 1888. The main result was to show that the cerebral centre of vision lies in the occipital lobe—occupying in the monkey the whole of that lobe, but as regards central vision being chiefly concentrated on its inner surface. Previously it had been held (by Ferrier, Gower, and others) that the angular gyrus represents the cortical centre for vision; but in the joint work above alluded to it was proved that this gyrus could be removed without any effect being produced on vision. It was also shown that appreciation of sounds is not confined in the monkey to the first temporal gyrus—the part which, when stimulated, causes pricking of the opposite ear and movement of the eyes to the opposite side—for not only could this gyrus be removed, but all the rest of the temporal gyri could be destroyed or removed on both sides of the brain without any marked impairment of hearing. This was also contrary to the generally received doctrine which postulates that the appreciation of sounds is confined to the cortex of the temporal lobe and is chiefly situated in the first temporal gyrus. On his return to America Dr. Brown continued for a time to carry on experiments on the monkey's brain, but the time occupied by these experiments proved incompatible with the claims of a growing practice, and he had reluctantly to relinquish them. Of late years he practised entirely as an alienist, having been for twenty-three years head of a large mental sanatorium at Kenilworth, a few miles north of Chicago.

We regret to announce the death of JOHN DONAL CARROLL, M.C., M.D., medical officer of health for Cork, who died recently at the early age of 38. Dr. Carroll, who was the fourth son of the late Vincent S. Carroll, Dundalk House, Dundalk, studied medicine at University College, Dublin, and graduated M.B., B.Ch., B.A.O. in 1913. He received a commission in the R.A.M.C. in August, 1914, and served in Gibraltar, Malta, Egypt, and France, and won the Military Cross in April, 1917, for attending the wounded at an observation post, although the enemy continued to concentrate heavy shell fire on it. During the attack on Ypres in August, 1917, his dressing station was blown up, and though he was not wounded he suffered severely from shell-shock. He later served with the Army of Occupation until 1919. After leaving the R.A.M.C. he

decided to specialize in public health work, and in September, 1920, he obtained the D.P.H. and graduated B.Sc. of the National University of Ireland in public health, both with first-class honours; he was the first in Ireland to obtain the latter distinction. He then served for some time as school medical officer under the London County Council. In August, 1922, he was asked by Dr. M. R. J. Hayes to organize the sanitary work of the Free State Army, and he held the post of chief sanitary officer in the Free State Army until September, 1925, when he was awarded a Rockefeller Fellowship for the purpose of studying public health work in the United States. He studied at Johns Hopkins University, and obtained the Doctorate of Public Health. He was the first medical officer of health appointed under the new Free State scheme, and took up work in Cork a year ago; he completely organized the public health work of the city, especially as regards tuberculosis and child welfare. He married in July, 1923, Shiela, daughter of Mr. J. J. Flynn of Dublin, and leaves one son and one daughter. He twice won the Free State Army golf championship, and during his university career twice represented University College, Dublin, in throwing the discus and putting the weight.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

ON May 7th the House of Commons read the Equal Franchise Bill a third time. Scottish Estimates for health, education, and agriculture were put down for May 8th, but progress was reported before they were discussed. On May 8th Mr. EVERARD obtained leave to bring in a bill to control the production, distribution, and sale of reconstituted and synthetic cream. He claimed that the bill was in the interests of public health; Dr. Vernon Davies was among its backers.

### National Health Insurance Bill.

ON May 3rd the standing committee of the House of Commons which is considering the National Health Insurance Bill considered Clause 14, which proposes to amend the provisions of the principal Act respecting the application of surpluses by approved societies. Sir THOMAS DAVIES moved to add "for the support of district nurses" to the purposes enumerated in the bill as those for which approved societies may make occasional subscriptions or donations out of their disposable surpluses. He said this addition would be valued all over the country.

Mr. RHYNS DAVIES said there would be strong opposition to the suggestion. Officials and members of approved societies objected to putting on the funds of the societies expenses which ought to come out of the local rates or from the Exchequer. Sir Thomas Davies's proposal was to take £1,000,000 or £2,000,000 from the funds of the approved societies and relieve the voluntary institutions of the country of the duty of collecting the money. This amendment, if passed, would compel the societies to reduce the £1 sickness benefit by 2s. 6d. or 5s., and hand over that money to an institution.

Mr. CHAMBERLAIN said that it was relevant to the amendment, which only concerned the granting of charitable institutions to which he was granting occasional subscriptions; it was not relevant to the surpluses of approved societies. He should not accept the amendment. A society could fairly argue that by an occasional donation to a district nursing association it would incur expenses which might become a charge on its funds. He said that district nursing associations were covered in the bill by authorizing gifts to "other similar institutions" which doubt had been expressed on that.

Mr. CHAMBERLAIN pointed out that the schedule of additional benefits which was appended to the bill already provided for the payment of the whole or any part of the cost of the provision of nurses for members. Under that an approved society could engage its own nurses. But if Mr. Chamberlain thought the amendment was an improvement he would not carry his protest further.

Mr. BRIANT said it was absurd for every society to think it could provide its own nurses. In many cases the medical man, who would perhaps only go to see a patient once a day, was of less service than the district nurse.

Mr. MELLER said the amendment was not a development of the additional benefit schemes. If there was sufficient money for a nursing scheme the society would come forward with one and the Minister would agree. The amendment was to meet the case where a society had already allocated the greater part of its surplus to other schemes and had a small amount over, which it might use for charitable purposes from time to time.

Dr. VERNON DAVIES asked whether the committee understood the distinction between district nurses and nurses. At present it was dealing with district nurses. District nurses visited patients once or twice a day. They were often run as charitable institutions, and he saw no reason why approved societies should not

be allowed to contribute a little toward their fund. All insured persons had a claim on the services of these nurses, whether they paid or not; they simply went on the recommendation of the doctor.

The amendment was agreed to.

Dr. WATTS moved to authorize the grant from the disposable surplus of subscriptions or donations for the provision of x-ray examinations in cases of fracture or suspected fracture. He said an x-ray photograph was necessary in the interest of the patient and of the doctor. In recent cases the courts had held that failure by a doctor to get an x-ray photograph rendered him liable to an action for damages if anything went wrong with the fracture. A panel doctor had no means of getting an x-ray photograph unless he paid for it. The Cheshire Insurance Committee and the Flint Insurance Committee, among others, had asked Dr. Watts to bring forward this claim. The cost would be trifling.

Sir KINGSLEY WOOD said anything that could be done to secure proper examination of fractures would be done if the finances of the societies permitted. The amendment proposed by Dr. Watts could not appropriately be inserted in the clause under consideration. If Dr. Watts merely wished to encourage hospitals which were doing x-ray examinations, the society could give them an occasional subscription. If he asked that the committee should provide for x-ray examinations, that should be considered under the first schedule of the bill, and could be discussed on an amendment in the name of Dr. Shiels. [This amendment proposes to insert the following new benefits: "The payment of the whole or any part of medical or surgical specialist services. The payment of the whole or part of the services of a midwife or medical practitioner in cases of confinement. Medical treatment or attendance for any person dependent upon the labour of a member."] Dr. DAVIES said he understood that insured persons were entitled to the best medical attendance.

Sir KINGSLEY WOOD said they were entitled to the attendance mentioned in the Act.

Dr. DAVIES said if a doctor did not make an x-ray examination he might miss a fracture altogether. If a doctor was not certain, how, under present conditions, could a patient obtain the best skilled attention?

Sir KINGSLEY WOOD said if the committee desired to discuss whether x-ray examination came within the duties of the ordinary medical practitioner or not, it must do so on another part of the bill.

Mr. BRIANT asked whether there was any part of the bill in which the committee could insert provisions to secure the payment of x-ray examinations.

Sir KINGSLEY WOOD said the question might be dealt with on the first schedule of the bill.

Dr. WATTS then withdrew his amendment.

Dr. DAVIES moved to provide that additional benefits should be administered by the society or branch of which the persons entitled to the benefits were members, except where the benefits were in the nature of medical benefits. He said this was a controversial subject on which, as he had retired from practice, he could speak for the medical profession in an unbiased way. Before the National Health Insurance Act of 1911 the lay committees of the friendly societies had got the idea that it was reasonable and proper that they should employ or engage medical men. When the national health insurance scheme was framed the medical profession as a whole had formed the opinion that, being members of a learned profession, it was not conducive to their dignity or position that they should be managed by a committee of lay people, particularly regarding medical treatment or medical benefit. The approved societies saw no reason why, under the national health insurance scheme, they should not have control of the doctors. The State intervened and made regulations by which medical men were not put under the power of the approved societies, which had never been able to get over their disappointment. There was even now a slight, veiled antagonism to the medical profession, and the idea that it was out to protect its own interests, irrespective of anything else whatsoever. The State, the approved societies, and the medical men should be co-operators, none superior to the others. The approved societies would have to recognize that they were one of three equal parties. The medical profession also had no desire to be superior to the approved societies, but most definitely would not work under them. The National Health Insurance Act, 1924, Section 75, Subsection 5, provided that where benefits were in the nature of medical benefit they should be administered by and through the Insurance Committee. He maintained that by that subsection the State recognized that medical men should not in any circumstances be placed under the supervision or control of approved societies on the question of medical benefit. It was now proposed to delete this subsection, the view of the Minister being that it was unnecessary or unworkable. The medical profession said that the subsection was a safeguard and should not be deleted, lest the approved societies should be able to re-establish the position, as regards additional benefit of a specialist or consultant character, which the profession thought had been ended by the Act of 1911. The profession had confidence in the Minister of Health, but he would not always occupy that office. The Minister might make regulations to ensure that the point would be safeguarded, but regulations depended on the personality of the Minister. The medical profession said the subsection was the only safeguard it had, and that the schedule of the bill relating to additional benefits would make possible the establishment by approved societies of ophthalmic clinics.

Mr. CHAMBERLAIN said that in his endeavour to avoid the difficulties caused by Section 75 (5) of the existing Act, Dr. Davies was creating fresh difficulties. Dr. Davies knew that administration by Insurance Committees of additional benefits in the nature of medical benefit was impossible, and he had cut it out, but he

did not say who was to administer these benefits. If the Minister was left to provide by regulation under Clause 14 (3) for the administration of these benefits, they would be administered by a joint body, on which the medical profession and the approved societies would be represented. They could rely on the good sense and fairness of Parliament to see that these regulations were not reversed.

Mr. HARNEY asked why the Ministry proposed to change the arrangement whereby approved societies administered additional benefits of a cash character and Insurance Committees those of a medical character.

Sir KINGSLEY WOOD said that Insurance Committees were not appropriate bodies to administer the new dental and ophthalmic benefits. So long as the subsection cited by Dr. Davies was in existence it was impossible for administration to be by a joint body on which approved societies and members of the medical profession would sit.

Remarking that he had made his protest, Dr. DAVIES withdrew his amendment.

Mr. RHYNS DAVIES moved to omit a provision regarding additional benefit which ran: "Regulations may be made with respect to the administration of schemes under this section and of any additional benefit, and with respect to the arrangements for the provision of any service or appliances towards the cost of which payment may be made by way of additional benefit; and any scheme providing for any additional benefit shall, except so far as the Minister may otherwise direct, have effect as if the regulations relating to the benefit were incorporated in the scheme, and the provisions of the scheme made subject thereto." He said he did so to secure information about the projected establishment of dental and ophthalmic clinics. The whole country could not be covered with clinics, nor could insured persons be compelled to attend them. He hoped clinics would be set up by approved societies in association. If the societies were only allowed to do so singly the large societies would alone be able to establish clinics. He assumed clinics would be established in Manchester, Liverpool, Glasgow, Cardiff, and London. The regulation to be issued should make perfectly clear that the insured person had freedom of choice, and should not be compelled to attend against his will. The dental profession had secured their status, and the antagonism between them and the British Medical Association was not as great as that between the medical profession and the people who practised optics. The panel doctor and the dentist had been definitely fixed into the national health insurance scheme, but an approved society did not at present compel an insured person to go to an ophthalmic surgeon, though some approved societies paid the expenses of an ophthalmic surgeon, who would give the patient a prescription to take to the optician who provided the glasses. The ideal would be to send every insured person to a qualified medical man who had specialized in eye diseases and for his prescription to be made up by an optician, but, as a member of the Departmental Committee which inquired into the registration of optical practitioners, Mr. Rhyms Davies thought that day was far distant. Did the Minister propose to allow the two systems to continue? Dr. Vernon Davies would say that there was a sufficient number of specialists in eye diseases, and that the Minister should lay down regulations whereby every insured person was first examined by one of them. The number of persons qualified to deal with the eye was about a thousand, and they were no more qualified than the best opticians. Even if there were a large number of specialists in eye diseases in the medical profession they would not live in the districts, such as the South Wales coalfield, where eye disease was most prevalent.

Dr. VERNON DAVIES approved generally of what Mr. Rhyms Davies said, but not that the best qualified optician was the equal of a qualified ophthalmic surgeon.

Mr. RHYNS DAVIES averred he had said the best qualified optician was as capable of providing a proper pair of spectacles as the ordinary medical practitioner who had not affected to be a specialist in eye diseases.

Dr. DAVIES said most general practitioners had no interest in the examination of eyes for spectacles. The British Medical Association said that there were in this country about a thousand doctors, experts in ophthalmology, who were prepared to work the scheme. The British Medical Association and the profession generally should be given their chance; the Minister should accept their offer to run the scheme.

Mr. HARNEY said that by the subsection under discussion any scheme formed by an approved society would be deemed to have incorporated in it regulations promulgated by the Minister. That would empower the Minister to say that persons receiving additional benefits must go to institutions or clinics set up by him.

Mr. CHAMBERLAIN said he had given a definite pledge to the House of Commons that a free choice must remain a feature of any scheme. To bind his successors he was ready to accept an amendment tabled by Mr. Whiteley which ran: "Provided that such regulations shall not restrict the right on the part of any insured person to obtain treatment from any practitioner, clinic, or other institution with whom arrangements with respect to that form of treatment have been made in accordance with the regulations."

Mr. MELLER asked if the Minister, before coming to a final conclusion with any professional body with whom he was negotiating, would submit the proposed terms to the Consultative Council.

Mr. CHAMBERLAIN said he was pleased to give that assurance. He added that he did not intend to authorize the setting up of a dental clinic by an approved society, managed solely by that society. These clinics were to be experimental, and managed by a joint body, representing both the professional classes and the approved societies. The question of the opticians and ophthalmologists was very important. Some defects of sight were not caused by mechanical alterations or faults in the construction of the eye,

but by disease. It was not always easy to decide whether eye trouble was due to disease or to a mechanical condition of the eye. It might always have existed or might have been caused by disease, and on that matter skilled advice was necessary. It seemed hard to say that a person should not go to an optician who was quite qualified to fit the patient with a glass which would correct his mechanical defect, when the patient could get that done much more cheaply in that way than by consulting an ophthalmic surgeon. On the other hand, he might, by doing so, commit a grave mistake, the consequences of which might even be fatal to his eyesight. He did not think it possible at this stage to lay down a general rule or regulation providing that every insured person who suffered from an eye defect must go to an ophthalmic surgeon first. There was not always a surgeon handy. It was not the intention of the regulation to attempt to enforce a practice which he did not think could actually be carried out, though it was the ultimate ideal at which they aimed.

Dr. FREMANTLE said he had been asked to speak by representatives of the Dental Service Association and of the British Dental Association. The experimental clinics mentioned by the Minister would be of great value. The Dental Association had feared a return to the old position where medical and dental clubs were run by approved societies, who made a profit out of the professional work and did not give proper attention to medical considerations. The medical profession would support the dental profession against such practices. The societies which had approached him suggested there was danger if any body of persons set up a clinic, and they would demand a voice in the management. They had to trust the Minister to ensure by regulations that the management gave weight to professional considerations and did not unduly consider the financial side. The Minister had made out a case for regulations the committee could not resist, but he wished the procedure could be improved to give the House of Commons greater facilities for supervising such regulations.

Mr. BRIANT said there was a difference between dental clinics and any other form of medical treatment. Panel patients as a rule seemed to enjoy going to see a doctor, and the master the medicine the more confident they were it would do them good, but there was difficulty in getting people to go to a dentist at all, and it would be still more difficult to get them to go to a clinic. People regarded a clinic as an institution where they had to line up, and as something quite different from going to their own private practitioner or private dentist, where they made an appointment and felt they got the kind of attention they would not get at a clinic. Yet if approved societies were to give large amounts from their surpluses for the establishment and maintenance of dental clinics, heavy pressure might be put upon patients to attend them. Mr. Briant wished that dental clinics could be removed from the list of establishments coming under the approved societies.

Mr. WOMERSLEY said he took it that, as in the past, the Minister was going to use opticians affiliated to the Qualified Opticians Council for supplying the glasses required. Some 4,000 opticians were properly qualified and recognized by the Minister for such supply, and 95 per cent. of cases of eye trouble were merely refraction cases or simply required eye testing. Qualified opticians feared the power to be given to the Minister would be used to destroy the existing arrangements, which had worked well.

Mr. BARKER suggested that the new regulations should provide that where an optician found eye disease he should send the case to a specialist.

Mr. MELLER said that if approved societies were to avoid heavy payments for ophthalmic treatment and deal justly with the insured people, there must be better co-operation between the medical profession and the societies—something different from the certificate which had been issued wholesale by practitioners throughout the country that the patient required to be examined by an ophthalmic surgeon. In half these cases the medical man could not have said what was the matter, and could not have justified the suggestion that the patient should go to an ophthalmic surgeon. If he spoke honestly he would have said the optician was in a better position to determine the matter. If the honest panel practitioner and the honest optician co-operated, not for self, but in the interest of those requiring treatment, then the funds at the disposal of the Minister and of the societies would provide that every genuine case went to the ophthalmic surgeon. Mr. Meller welcomed the suggestion of Dr. Davies that there should be co-operation between the societies and the doctors, but said the desire for co-operation was greater on the part of the approved societies than he had found it on the part of the medical profession.

Dr. SINCLAIR said he still had some anxiety about the sanctity of the free choice of dentist. He asked how the competition between the dentists connected with the clinic and those outside would be maintained.

Mr. CHAMBERLAIN said he could give no further assurance. Mr. RHYS DAVIES then withdrew his amendment, and Mr. Whiteley's amendment, as previously read out by Mr. Chamberlain, was added to the bill. Amendments moved by Mr. WOMERSLEY and Mr. BRIANT were negatived, and Clause 14 was added to the bill.

When the standing committee resumed on May 8th Dr. SHIELDS moved a new clause to amend the principal Act in the section dealing with maternity benefit by providing that Subsection (1) of Section 14 of the principal Act shall have effect as if the following words were added at the end thereof: "in addition to treatment and attendance by a duly qualified medical practitioner or by a duly certified midwife." He said that the money now provided for maternity benefit was not always used to provide attendance by medical men or midwives, and if the Minister could meet the

amendment he would gratify public opinion, which was perturbed at the fact that mortality in childbirth was not decreasing, and had remained practically the same for a hundred years.

Sir KINGSLEY WOOD said the whole committee would sympathize with the amendment, but he could not advise acceptance. The amendment would cost the national health insurance scheme £1,500,000, and would upset the finances of the whole scheme.

Dr. FREMANTLE hoped the approved societies would turn their attention to the subject. These societies often thought less of the medical needs of the population than of the cash needs of their members. If part of the cash maternity benefit of 40s. could be converted into a medical benefit, with the attendance of a qualified practitioner or midwife, the country would prevent many of the 3,000 or 4,000 deaths occurring in childbirth every year.

Dr. SIMES said the report of the Royal Commission showed that money could be got if certain arrangements were made. He trusted that the approved societies would take the matter into consideration. The first object of the Act was to give adequate medical attendance to the people. He begged to withdraw his amendment.

Mr. RHYS DAVIES proposed a new clause to add dental treatment and ophthalmic treatment, with the cost of optical appliances, as statutory benefits. At present societies with large surpluses could give these as additional benefits, while other societies could not. Was it possible to secure part of the surpluses of some societies in order to give these as statutory benefits?

Sir KINGSLEY WOOD asked where the money was to come from. The Royal Commission on National Health Insurance had calculated that the cost of a complete dental service would be £4,500,000 a year. Nothing approaching that sum was now spent as additional dental benefit. He could not accept the proposed clause. They could understand a member of the medical profession having no regard to the amount of money to be spent, but they expected more regard from an administrator of an approved society, as Mr. Rhys Davies was.

Dr. FREMANTLE protested against the reflection on the medical members of Parliament.

Mr. RHYS DAVIES withdrew his amendment and proposed another to provide that an approved society with branches separately valued should be entitled partially to pool its surplus in order to help branches with a deficiency. Had it been in order the Labour party would have proposed a partial pooling of surpluses throughout the country. Societies covering 1,500,000 insured persons supported his proposal.

Sir KINGSLEY WOOD said the proposed clause was supported only by societies with one-half of the total membership possessed by societies with branches. The Royal Commission made no recommendation in favour of the clause, nor did the Consultative Council. The Minister of Health had given the House of Commons a pledge that pooling would not be dealt with by the present bill. He trusted Mr. Rhys Davies would not press his proposal.

Mr. WHITELEY said they should now attempt to make the Act into a National Health Insurance Act. All these years since 1911 they had been tinkering at it, and it had never met the requirements.

The clause was rejected by 21 to 11.

Dr. WATTS moved to add to the statutory benefits under the principal Act "the payment of x-ray examinations, in cases of fracture or suspected fracture, when such examination is recommended by the insurance practitioner." That this was desirable was agreed by approved societies and local Insurance Committees. It was wrong that a panel practitioner should have to treat fractures without an x-ray photograph. This new benefit would cost very little.

Mr. RHYS DAVIES remarked that Dr. Watts would not have moved his amendment if it were not that the doctor who took the radiograph would be paid for it. He had not indicated what the fee would be. For every x-ray examination the doctor would get two or three guineas.

Dr. VERNON DAVIES said that seven or eight years ago the fee was half a guinea.

Mr. RHYS DAVIES said that if that were so the fee would be three guineas now.

Sir KINGSLEY WOOD said that to add this to the statutory benefits meant increased cost, and he could not advise the committee to accept the amendment.

The clause was negatived without a division.

The first schedule specifies the additional benefits which may be given by societies with surpluses. The first of these additional benefits is "an increase of sickness and disablement benefits." Dr. SHIELDS moved to add thereto "in the case either of all members of the society or of such of them as have any children or any specified number of children wholly or in part dependent upon them." He said this had appeared in the original Act, but had been dropped because it had never been put into use.

Sir KINGSLEY WOOD said that to reinstate this provision would be undesirable. It had been deleted at the recommendation of the Royal Commission. It did not provide for the dependent wife. If there were to be allowances to dependent children they should be introduced as part of a general scheme.

Mr. RHYS DAVIES opposed the amendment. Dependents' allowances were not insurance, but savoured of Poor Law relief. He objected to Acts advertising benefits under the scheme which could not be paid.

The amendment was defeated by 17 to 8, and the committee adjourned till May 10th.

Replying, on May 2nd, to Mr. Bromfield, Mr. CHAMBERLAIN said he was not prepared to allow regional medical officers' fees paid by approved societies to be charged against the benefit fund account instead of against the administration account. The fees were part of the administrative expenditure, and must under the Act

be charged to the administration account. He had no reason to think they could not be met out of that. They amounted on the average to less than a halfpenny per member per year.

During his statement on national health insurance in Northern Ireland (a statement made to the standing committee on the National Health Insurance Bill, and briefly reported in the issue of the *Journal* for May 5th, p. 777) Dr. SINCLAIR said the suggestion that Northern Ireland should be excluded from the common valuation under the national health insurance scheme would practically compel it to establish a health insurance scheme of a nature similar to that which existed in Great Britain. That would be an extremely complicated business, because the dispensary system, which had existed in Northern Ireland for several generations, would require to be remodelled by the establishment of medical benefits similar to those existing in England and Scotland. The Minister for Home Affairs in Northern Ireland had appointed a Commission to look into the affairs of Poor Law administration in that country, and a report had been furnished to the Government of Northern Ireland at the end of last year. The Minister of Labour in Northern Ireland acted for the Ministry of Health, and had adopted a medical referee system, of which the health societies availed themselves freely. The certification system in Northern Ireland left something to be desired, but the medical referee system now in force would soon help to correct any alleged irregularities of certification. He begged the committee to hesitate before accepting the amendment, and to give the Government of Northern Ireland time to remodel their local government services, and with them the dispensary system, thereby bringing Northern Ireland into line with Great Britain. Northern Ireland was far too small an area to support a national health insurance scheme of its own. The dispensary system that prevailed in Northern Ireland suited admirably the large agricultural areas, but it was not so much availed of in the industrial areas. If sufficient time were given, it might be that, in the long run, a new scheme of health benefits would be adopted in Northern Ireland.

#### Small-pox.

Answering Dr. Fremantle, on May 3rd, Mr. CHAMBERLAIN said the report of the Departmental Committee on Vaccination was being printed, and would be ready at an early date.

On May 3rd Mr. BROMFIELD asked what means were adopted by the officials of the Ministry of Health to determine whether samples of lymph contained vaccinia virus. Mr. CHAMBERLAIN said the methods adopted in pursuance of Article 8 in Part 1 (B) of the second schedule to the regulations were those of Calmette-Guérin, Gins, Sobernheim and Groth, which were recommended by the Small-pox and Vaccination Commission of the League of Nations. Mr. BROMFIELD asked what were the characteristic lesions due to vaccinia virus referred to in the Therapeutic Substances Regulations. Mr. CHAMBERLAIN said the characteristic lesions referred to were the production of the specific and characteristic vesicles on the rabbit's skin, inflammation with cloudiness and opacity of the cornea of guinea-pigs and rabbits, and local areas of infiltration of definite size and appearance in the case of the intradermal method. Mr. BROMFIELD further asked to what extent rabbits were used for the purpose of propagating lymph in the Government establishment; and when they were first brought into use for that purpose. Mr. CHAMBERLAIN answered that during the last six months the number of rabbits used was twelve. Rabbits for this purpose had been systematically used since 1902, and for two years previously in preliminary experiments.

Mr. BROMFIELD asked whether, in view recently published third edition of *Manual of Infectious Diseases* in regard to the various sources of vaccine lymph produced in the Government lymph establishment, Mr. Chamberlain would state what means were used by his officials for ascertaining whether the viruses obtained from so many different sources were identical in their character, particularly in view of the fact that no causal germ specific to vaccinia had been discovered. Mr. CHAMBERLAIN said the statement in the publication cited as regards the various sources of vaccine lymph appeared to refer to vaccine lymph in general, and not to the lymph used at the Government lymph establishment. The records showed that the lymph now used at the Government lymph establishment was derived from calf lymph originally obtained from Cologno, and the strain had since been carried on by repeated transference from animal to animal. In these circumstances the question of ascertaining whether different viruses were identical in character did not arise.

An outbreak of small-pox in Lichfield Poor Law Institution has been notified to the Minister of Health; it did not occur in the casual wards, which, with his sanction, have been closed since 1925.

#### Output of Morphine.

In an answer to Mr. Scrymgeour, on May 7th, Mr. LOCKER-LAMPSON said he was not aware that between 1921 and 1926 the world output of morphine increased from 30 to 60 tons. A statistical survey recently issued by the League of Nations gave the figures as about 30 and 40 tons respectively, but both figures were incomplete. The 1926 figure included quantities of morphine which were produced solely for transformation into non-dangerous products such as codeine. The quantity of morphine manufactured for sale as such was far smaller. In Great Britain the manufacture of morphine had shown a steady decrease during the last five years. Mr. Locker-Lampson said he was not aware that the Italian representative on the Advisory Committee charged

the British Government with concealing its drug exports. He called attention to the fact that the amount of raw opium returned by Great Britain as exported to the United States was less than the amount of raw opium returned by the Government of the United States as imported from Great Britain. This discrepancy was being examined by the two Governments. It was probably due in part to the fact that the returns related to different periods, the British being for the calendar year, the American from July to July, and in part to the fact that opium sold from Great Britain might actually be exported from Great Britain, but shipped direct from a foreign port to the United States. There was no reason to question the accuracy of the British official figures.

In a previous answer to Mr. Scrymgeour, on May 2nd, Sir AUSTEN CHAMBERLAIN denied that the British representatives on the Opium Committee of the League of Nations had opposed the efforts of the Italian representative to prevent the Opium Control Board being made independent of the League and representative only of the interested Government. The point at issue was the relation of the secretariat of the Board to the secretariat of the League, and the British representatives, with some other members of the Opium Committee, acted in the belief that the views they put forward gave effect to the intentions and provisions of the Opium Convention.

Lieut.-Commander KENWORTHY asked if Mr. Locker-Lampson was aware that the figures he had read out did not include one showing that the total world requirement for medicinal purposes was only 15 tons, and that at least twice as much was being manufactured. He asked why Parliament should not take drastic steps to prevent an excessive amount being manufactured and sent out by profit-making firms in this country. Mr. LOCKER-LAMPSON replied that for that reason the British Government had ratified a convention setting up a Board of Control.

*Treatment of Venereal Disease.*—Miss LAWRENCE asked Mr. Chamberlain, on May 3rd, the amount of grant given towards the treatment of venereal disease in the years 1921 and 1927, and the amount which local authorities had been informed was the maximum they would receive for the year 1927-28; the number of treatment centres for venereal disease in England in 1921 and at the present time; and the number of health authorities where no such centres were provided. Mr. CHAMBERLAIN replied that the grants paid to local authorities for this purpose amounted to £241,687 and £272,921 during the financial years 1921-22 and 1927-28 respectively. The maximum grant payable to these authorities in respect of the financial year 1927-28 was £286,763. There were at present 177 treatment centres in England, compared with 184 in 1921, the reduction being due mainly to the policy adopted in some large towns of concentrating the work of two or more centres in one centre, at which the facilities for treatment had been extended. Facilities for the treatment of venereal disease had been provided by all the local authorities responsible for this work, but in a few cases the treatment centres were outside the administrative areas of the authorities.

*Tuberculosis: Cost of Sanatorium Treatment.*—Mr. CHAMBERLAIN announced, on May 3rd, that the average cost of residential treatment in tuberculosis sanatoriums during 1926-27 was 49s. 3½d. per patient per week. The total sum spent in any year on sanatorium treatment proper was not separable from the amounts spent on other treatments of tuberculosis. Dr. VERNON DAVIES asked whether the accounts could be altered in future years to give the cost of sanatorium treatment. Mr. CHAMBERLAIN said it was difficult to separate sanatorium treatment from other treatment in residential institutions. Answering a further question by Captain BOURNE, Mr. CHAMBERLAIN said the tuberculosis schemes of all local authorities provided for the observation of patients discharged from sanatoriums. He had no figures to show the percentage of such patients who were permanently cured of tuberculosis.

*Procedure regarding Discharge of Certified Persons.*—Mr. RICHARDSON asked the Minister of Health, on May 3rd, if, according to a recent ruling of the Board of Control, the procedure under Section 49 of the Lunacy Act of 1890 for the examination of a certified person by two doctors with a view to discharge was now held to require that the two doctors, instead of visiting once each with an interval of seven days and giving an independent opinion, should visit the patient together on two separate occasions with a like interval of seven days; and whether he would introduce legislation at an early date to simplify and facilitate the procedure so as to place the opportunity for discharge conferred by this section within reasonable reach of the poor. Mr. CHAMBERLAIN replied that the ruling of the Board of Control was given after full consideration of the terms of the section. The point raised had been noted for consideration in the event of fresh legislation being introduced.

*Miners' Phthisis due to Rock-boring.*—On May 3rd Sir WILLIAM JOYNSON-HICKS, who was asked by Mr. GRENFELL about the extension of the schedule of industrial diseases to include men who contracted miners' phthisis while rock-boring in coal mines by compressed air machines, said the matter would have to be dealt with by a scheme under the Workmen's Compensation Act, 1925, and he had asked the Departmental Committee on Workmen's Compensation for Silicosis to advise as to the terms of a scheme. He had offered for this purpose to appoint to the committee two representatives of the industry on each side, but had not yet received the reply of the Miners' Federation. The disease was not notifiable, and no statistics were available, but its incidence, to a limited extent, in the coal-mining industry had been established.

**Duties of Registrars of Births and Deaths.**—On May 7th Mr. CHAMBERLAIN told Sir C. Oman that a registrar of births and deaths was required by regulations to report to the coroner every death which, on the information before him in the medical certificate or otherwise, was due to any one of certain prescribed causes or occurred in certain prescribed circumstances, and, pending consideration by the coroner, to defer registration and the issue of an authority for burial. He had thus no discretion to decide whether to report such cases or not. He (Mr. Chamberlain) was aware of no reason for apprehension that registrars of births and deaths did not discharge faithfully the duties of their office in those cases where they also held Poor Law office.

**Milk Production in England and Wales.**—On May 7th Mr. GUINNESS, in reply to Mr. R. Young, stated that the total amount of milk produced in England and Wales during the past two years, exclusive of milk fed to calves and pigs, but inclusive of milk manufactured into various products, both on and off farms, as well as milk consumed in liquid form, had been estimated as follows: June to May, 1925-26, 1,135 million gallons; June to May, 1926-27, 1,150 million gallons. "Certified," "Grade A (T.T.)," and "Grade A" milk constituted approximately 1 per cent. of the milk consumed as liquid milk. No reliable estimate for "pasteurized" milk was available. The terms "clean" and "purified" were not recognized as official designations; they were entirely relative terms, and the quantities of milk sold under them were unknown.

**Dysentery in a Prison Camp.**—On April 30th Mr. AMERY informed Mr. Renne Smith that his latest information on the outbreak of dysentery in a prison camp at Malaita was given in a reply to a question on April 17th. So far as his information went, only one of the natives was arrested by the end of October last. Arrests were still being made in February. The trials would ordinarily be conducted by the chief magistrate of the protectorate, but he had to leave the protectorate owing to ill health, and another judicial officer had to be sent to the protectorate from Fiji. He (Mr. Amery) proposed to await the report of the High Commissioner before deciding whether any inquiry by the Special Commissioner in regard to happenings between the arrest and trial of the prisoners was desirable. Until he received that report he was not prepared to enlarge the present scope of the inquiry.

**Insanitary Areas in Plymouth.**—On May 1st Sir KINGSLEY WOOD told Mr. Hore-Belisha that the Minister of Health had seen the report of the medical officer of health for Plymouth for 1927, in which he stated, with reference to the three insanitary areas which he scheduled in Plymouth more than three years ago, that it appeared almost incredible that the short, though necessary, formalities regarding his representation should still be incomplete and that matters should have advanced so little towards any definite end. A scheme dealing with one of the areas in question had been submitted to the Minister, and he had directed a public inquiry into the scheme. He was making inquiry as to the other two schemes. The report of the medical officer of health for 1927 stated that upwards of £100,000 was spent by owners of insanitary property in Plymouth on repair work during the years 1924-27.

**Rating of Voluntary Hospitals.**—Sir KINGSLEY WOOD, replying to a question, said that no complete statement of the amount of rates paid in respect of voluntary hospitals was available. In the opinion of the Minister of Health any proposal to de-rate voluntary hospitals must be considered in relation to similar claims made on behalf of other charitable and public institutions.

**Ethyl Petrol.**—Sir PHILIP SASSOON stated, on May 2nd, that ethyl petrol was used by high-speed aircraft during practice flights in the Air Service. The Royal Air Force had been experimenting for four years with this spirit, and had no evidence to show that it was more dangerous than ordinary spirit.

#### Notes in Brief.

In 1926-27 the gross expenditure on the school medical services was £151,695 and the receipts £66,010.

During the twelve months ended March 31st, 1928, 14,714 animals were cremated on account of foot-and-mouth disease, and 621 were buried.

During 1927 there were 1,028 fatal and 172,883 non-fatal accidents at mines under the Coal Mines Act, resulting in 1,128 deaths and disablement for more than three days to 173,449 persons.

In 1927 there were 48 fatal accidents in the Royal Air Force, with 55 deaths; in 1928, to April 24th, there had been 15 fatal accidents with 24 deaths.

The Minister of Health cannot reconsider the decision not to allow the use of sulphur dioxide in the treatment and milling of barley.

The birth rate for the administrative county of London in 1927 was 16.1 per 1,000. The boroughs with the highest birth rates were Shoreditch (20.7) and Bethnal Green (20.0).

At the beginning of April 2,685 maternity and child welfare centres were known to the Ministry of Health in England and Wales as against 2,575 a year previously.

Sir Kingsley Wood states that he cannot give an assurance that the proposed Local Government Bill will await the report of the Royal Commission on Local Government.

In Glasgow, on March 31st, the number of houses inhabited but certified unfit for human habitation was 3,007.

The governors of the Royal Veterinary College are endeavouring to obtain the necessary funds to rebuild the College, and the Ministry of Agriculture has promised a grant of £35,000 on a pound for pound basis.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

At a congregation held on May 3rd the following medical degrees were conferred:

D.M.—L. N. Jackson.  
B.M.—C. W. Flemming.

### UNIVERSITY OF LONDON.

#### UNIVERSITY COLLEGE.

In addition to those announced on April 28th (p. 740) the public lectures at University College, Gower Street, during the current term will include one by Professor Ross G. Harrison of Yale University, on "Modern trends in the study of animal development." The lecture, which will be given at 5.30 p.m. on Monday, May 21st, is addressed to students of anatomy, physiology, and zoology, and is open without fee or ticket.

### UNIVERSITY OF SHEFFIELD.

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B. (Part I).—J. D. Gray, Bessie Hatherley, Thos. M.B., Ch.B.—W. H. Carlisle, A. Cohen, F. Ellis, R. B. Gould, Iris M. Moody, S. K. Pannikar, T. H. Pudar, L. Slesnick, J. H. Whitbourn.

\* With distinction in pathology.

† With distinction in anatomy, pathology, and pharmacology.

### UNIVERSITY OF DUBLIN.

#### TRINITY COLLEGE.

At the first summer commencement of Trinity Term, held on May 5th, the following medical degrees were conferred:

M.D.—W. R. Aykroyd, L. C. Brough.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on May 1st, when the president, Dr. Robert A. Fleming, was in the chair.

Dr. James Thomson was introduced and took his seat as a Fellow of the College. Dr. John Howes McDougall and Dr. Anna Justina Augusta Wilson were elected Fellows.

Alfred Joseph Clark, Margaret Black Martin, David Taylor Mackie, Joseph Ryland Whitaker, and Mohamed Abd El-Hamid Gohar, were elected members of the College.

Dr. Robert Thun was elected a representative of the College on the Conjoint Committee of Management of the Triple Qualification. Dr. William Russell was elected the representative of the College on the General Council of Medical Education and Registration.

The Lister Fellowship was awarded to Dr. Charles G. Lambie, F.R.C.P., for his work on carbohydrate metabolism.

At an extraordinary meeting held the same day, Dr. Walter Tyrrell Beeson was elected a Fellow of the College.

## Medical News.

THE next session of the General Medical Council will commence at 2 p.m. on Tuesday, May 22nd, when the President, Sir Donald MacAlister, Bt., K.C.B., M.D., will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

THE next quarterly meeting of the Royal Medico-Psychological Association will be held on Wednesday, May 16th, at the British Medical Association House, Tavistock Square, W.C.1, under the presidency of Dr. Hamilton Maw. The ninth Maudsley Lecture will be given, at 3.30 p.m., by Sir John Macpherson on "The new psychiatry and the influences which are forming it."

PROFESSOR W. E. DIXON will deliver a Chadwick public lecture on June 7th, at 5 p.m., in the Chelsea Physic Garden, on narcotic plants.

A MEETING of the Chelsea Clinical Society will be held on May 15th, at 8.30 p.m., at the Hotel Rembrandt, when Dr. J. H. Ruffel and Dr. O. L. De Wesselow will open a discussion on the clinical value of biochemical methods. The meeting will be preceded by dinner at 7.30 p.m., and after the discussion the annual general meeting of the society will take place.

At the meeting of the Biochemical Society to be held to-day (Saturday, May 12th), at 2.15 p.m., at the University of Birmingham, a number of communications will be made, including one by Mr. S. H. Edgar on the composition of the blood in acute rheumatism of childhood, and another by Messrs. E. M. Hume, H. H. Smith, and I. Smedley-Maclean on the biological examination of irradiated zymosterol for vitamin D.

At a meeting of the Royal Society of Tropical Medicine and Hygiene at 11, Chandos Street, W.1, on Thursday, May 17th, at 8.15 p.m., Dr. George W. Bray, medical officer of Nauru, Central Pacific, will read a paper on "Vitamin B deficiency in Infants: its possibility, prevalence, and prophylaxis." The paper will be preceded, at 7.45, by a demonstration to illustrate the subject.

THE London Clinical Society has arranged a clinical evening, to be held at the London Temperance Hospital, Hampstead Road, N.W.1, on Thursday, May 17th, to which all medical practitioners are invited. Cases will be shown from 8.15 p.m., and the chair will be taken at 9 p.m. Smoking will be permitted and refreshments provided.

At the meeting of the Royal Microscopical Society to be held in the Lecture Hall, 20, Manover Square, W., on Wednesday, May 16th, at 7.30 p.m., a communication will be made by Mr. G. F. Marrion and Dr. A. S. Parkes on the effects of infection and vitamin B deficiency upon the testes of the pigeon. The annual pond life and general microscopical exhibition will be held on June 6th, from 7.30 to 10 p.m.

THE annual medical missionary breakfast of the Medical Prayer Union will be held on Wednesday, May 16th, at the Refectory, University College, Gower Street, London. An address will be given by Dr. A. W. Hooker, Wesleyan Mission, China, recently returned from West Africa. An intimation of intention to be present will be welcomed by the honorary secretary, Dr. Tom Jays, Livingstone College, Leyton, E.10.

THE Midway Mission Hospital, Bethnal Green, which has now attained its jubilee, has recently completed the building of a new extension and the equipment of an x-ray department, and the formal opening of these additions will take place on Saturday, May 19th, on the occasion of the annual meeting and "pound day." In recent years the number of in-patients has doubled, and increased accommodation has therefore become necessary, not only for the patients, but also for the additional staff required. Out of £20,000 needed to complete the extension £13,000 has been given or promised, and a special appeal is now being made to secure the balance.

A POST-GRADUATE course commenced at the National Hospital, Queen Square, Bloomsbury, W.C.1, on Monday, May 7th; it will continue until Friday, June 23rd. The general course will consist of clinical lectures and demonstrations, teaching in the out-patient department, and pathological lectures and demonstrations. A course of lectures on the anatomy and physiology of the nervous system will also be given. Further particulars can be obtained on application to the dean of the Medical School.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Tuesday, May 15th, at 2.30 p.m., there will be a clinical demonstration by Dr. Thomas Cotton at the National Hospital for Diseases of the Heart, and that on the same day, at 5 p.m. at St. Mark's Hospital, Mr. W. B. Gabriel will give a demonstration of cases illustrating diseases of the rectum. A demonstration will also be given on Thursday, May 17th, at 1 p.m., at the Royal London Ophthalmic Hospital, by Mr. Whiting. The first of four demonstrations on ante-natal diagnosis and treatment will be given at the Royal Free Hospital by Professor Louis Mellorey at 5 p.m. on Wednesday, May 16th. Arrangements for June include special courses in chest diseases at the Victoria Park Hospital, from June 18th to 30th; in diseases of children at the Children's Clinic, from June 4th to 16th; in gynaecology at the Chelsea Hospital for Women, from June 18th to 30th; and in neurology at the West End Hospital for Nervous Diseases, from June 25th to July 21st. Particulars may be obtained from the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

At the meeting of the Society of Public Analysts held on May 2nd a communication on the separation of lead tetraethyl from solution in petroleum spirit was made by Messrs. F. W. Toms and C. P. Money. The method depends on the separation of lead ethyl sulphinate on passing sulphur dioxide into "ethyl petrol," and conversion of the deposit into lead sulphate.

THE Minister of Health has appointed Mr. A. B. MacLachlan to be a principal assistant secretary and Mr. M. Heseltine, C.B., to be an assistant secretary of the Ministry.

At a meeting of the council of the University of London Graduates' Association, held on May 7th, it was resolved to support the re-election as representative of the University in Parliament of Dr. E. Graham Little, M.P.

DR. LEWIS S. ROBERTSON, who has been appointed superintendent of the Pretoria General Hospital, has taken a prominent part in professional affairs in that city, notably as an officer in the local branch of the Medical Association of South Africa (British Medical Association). He received his early medical education at Capetown, and entered Aber-

deen University in 1913, but in October, 1914, joined the Scottish Red Cross and served in France for two years with that organization, subsequently holding a commission in the Royal Field Artillery. After graduating M.B., Ch.B. Aberd. in 1919 and obtaining the D.P.H. he returned to South Africa. Since 1922 he has been in practice in Pretoria.

WE have received the first number of a new scientific quarterly, published by direction of the Council of the Pharmaceutical Society, entitled the *Quarterly Journal of Pharmacy*. The four issues when bound into a volume for the year will represent the *Year-Book of Pharmacy*, which was first issued in 1870. The present volume contains an historical introduction by the President of the Pharmaceutical Society of Great Britain, and an account of the outlook in pharmacology and pharmacy by Sir John Roso Bradford, President of the Royal College of Physicians of London. Original articles include the pharmacological assay of digitalis by different methods, the composition and solubility of strychnine hydrochloride, the solubility and rate of solution of arsenious oxide *H.P.*, and a critical article on the oestrous cycle in the guinea-pig and the suitability of the uterus for the estimation of placental extract. The issue also contains abstracts of current literature. It should prove a very useful work of reference.

A MEDICAL congress will be held at Rio de Janeiro from July 15th to 19th. Further information can be obtained from the general secretary, Dr. Belmiro Valverde, Rua Sao José 84, Rio de Janeiro, or from Dr. Drugman, 18, Boulevard des Mondins, Monto Carlo.

THE eighth Italian congress of radiology will be held at Florence from May 14th to 16th, under the presidency of Professor Luigi Scilliano.

MESSRS. J. AND A. CHURCHILL announce for early publication two new volumes in the Recent Advances Series—*Surgery*, by Mr. W. H. Ogilvie, and *Disease of Children*, by Drs. W. J. Pearson and W. G. Wyllie.

ACCORDING to the census of 1926 the population of the Union of the Soviet Republics is 145 million as compared with only 104 million in 1897, so that in spite of the war, famine, and epidemics the population has increased by 40 per cent. in the last thirty years. During this period the number of urban dwellers has increased two-fold, while the increase in the rural population has been only 30 per cent.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563, and 9564* (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the *British Medical Journal*, *Aitology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Miscroscop Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*); telephone: 62550 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

## QUERIES AND ANSWERS.

### INCOME TAX.

*Appointment: New Consulting Practice.*

"M.D." has sold his practice in Harley Street and is living in the country. He has obtained a part-time appointment under the Ministry of Health, the work being done at a town eight miles away, and hopes to get some consulting work. What expenses can he deduct?

\* \* \* The receipts from the appointment are strictly assessable according to the rules of Schedule E, and if that course is followed the expense of travelling between his residence and the place where the work is done is not legally allowable. By custom

such receipts are usually merged in a practitioner's general earnings for assessment under Schedule D, and the objection to the allowance of travelling expenses is then waived. Unfortunately, "M.D." has no fund of general earnings with which the appointment receipts can be merged, and in such circumstances the concession referred to would not apply. We can only suggest that when "M.D." is called upon for a return he should request that demand be left over until he has been twelve months in the new work, and that he should then make an inclusive declaration deducting all travelling expenses and other costs incurred in doing the work and ask for the matter to be dealt with on that basis. As the car will presumably be largely used for private purposes, it may be best to keep a record of the mileage driven for professional purposes and divide the total car expenses proportionally.

#### *Deduction for Residence.*

"W.S." explains that since his last year's return was made he has purchased his house. What can he deduct in the form of rent?

\* \* The same proportion as was previously applied to the rent paid should now be applied to the net assessment under Schedule A on which "W.S." now pays income tax as the owner of the premises.

#### *Value of Board and Lodging.*

"J.C.H." was engaged as a temporary assistant on terms which provided for free board and lodgings; he is not staying under his principal's roof, but the cost of his board, etc., is paid for him. Is he liable for tax on the value?

\* \* He is not liable on any advantage which is not received in money or in a form capable of conversion into money; on that principle and on the facts stated he is not liable for tax on the value of the board and lodgings. If "J.C.H." made a return for assessment including that value as part of his statutory income he can claim back the tax paid in error—or have it set against the next instalment due—but if he left the assessment to be made in the absence of his return and then did not give notice of appeal within the statutory period of twenty-one days, we fear he has no legal remedy.

#### *Motor Car Transactions.*

"N.W.J." bought an E car in 1924 for £350 and sold it in 1927 for £75—when the price of a similar new car was £280. In 1927 he bought a W.K. car for £575. What should he claim?

\* \* (1) Obsolescence allowance, £350-£75=£275—but it is possible to contend that the allowance should be £280-£75=£205. (2) Depreciation allowance 1928-29, £575 at 15 or 20 per cent.

"H.A.T." bought a 11.4 h.p. car in January, 1926, for £250 and sold it in January, 1928, for £100, buying a 12.24 h.p. car for £230. His accounts have been made up to April 5th each year. What allowances can he claim?

\* \* Obsolescence allowance as an expense of the year 1927-28, the out-of-pocket expense—namely, £230-£100=£130, and depreciation allowance for 1928-29, 15 or 20 per cent. on £230. One point should perhaps be mentioned—that is, that as there was a slight increase in horse power it might be contended by the revenue authorities that there was some measure of capital expenditure involved in the purchase of the second car. The difference is, however, so small that it is thought that that contention would not be pressed seeing that the second car cost less than the former one.

### LETTERS, NOTES, ETC.

#### *SALARIES OF MEDICAL WOMEN.*

"N.O." writes: Your correspondent "County Medical Officer" (April 7th, p. 612) mystifies me when, referring to the small salaries of women assistants in general practice, he concludes that "Such a condition of affairs must react unfavourably upon the whole profession, and the first to suffer will be the male members of the public health service." I ask myself repeatedly "How?" but fail to find the answer. I agree with him wholeheartedly that well-qualified women do work for their board only, and that the addition of £3 a week is a relatively princely emolument to many. I admire such women for their courage and tenacity in sticking at all costs and sacrifice to their calling. Let not "County Medical Officer" commiserate with them. After twelve months' hospital experience I was offered £150 per annum (out of which I had to pay for my own board and lodging in an insanitary two-roomed cottage in the village) to act as assistant to a distinguished retired colonel. He himself lived with his small family in a charming and roomy house. I had too high an opinion of myself, and refused this post. About the same time I was offered a post under a South Wales medical aid society at £350 per annum; acting on the advice of the Secretary of the British Medical Association I courageously refused. After further clinical experience I succeeded in obtaining a public health post at salary of £600 per annum. Having worked for three years and paid off my financial obligations to my parents and my old school, I married, and for this offence was obliged to

resign my post. My desire to get back into harness, to justify my years of hard study, amounts at times almost to an obsession; moreover, I seriously need the help that a reasonably paid post would provide for a war-disabled husband and a small family. But I know that the position is hopeless in the face of this appalling state of unemployment amongst medical women. I would go further than "County Medical Officer" in stating that "it reacts unfavourably," etc.; I would say that it is a disgrace to the profession, and calls for smart action by the Association as a whole, and the Women's Federation in particular. Let them rouse themselves from their case. The closing of the medical colleges to women at any rate will save many from bitter disillusionments in the future. At the same time I feel sure that the power of such as those who countenance with unconcern this artificial attempt to subordinate women in the sphere of medicine cannot ultimately prevail. And so "County Medical Officer" and his hypothetically out-of-work colleagues will not have to tremble for long.

"A.M." writes to express his agreement with the letter of "County Medical Officer" with regard to the remuneration of medical women. He thinks that steps should be taken to reduce the entry of women into the medical profession in view of the serious overcrowding, as illustrated by the fact that fifty or one hundred women apply for small appointments. He adds that these "student appointments" are supposed to be suitable for six months, but are actually retained for long periods by women who have been in practice for four or five years.

#### *FIVE GENERATIONS ATTENDED BY ONE DOCTOR.*

Dr. JAMES ADAM (Hamilton, Lanarkshire) writes: Dr. L. J. Hood's experience (April 21st, p. 703) of attending five generations in one family has also been mine for some years past. I am hoping I may attend the sixth.

#### *UNUSUAL PIGMENTATION OF SCALP.*

Dr. G. G. COOPER (Bel-Abbes, Algeria) refers to the report by Dr. D. I. Walker (February 11th, p. 243) of the case of a boy who had a patch of jet black hair on the right parietal and frontal region of the scalp, the hair otherwise being of a sandy, fair colour. Dr. Cooper remembers a similar well-marked case in a boy aged 12-14, whom he saw in Edinburgh about twenty-five years ago. This boy had pronounced red hair, with an oval patch of black as large as a hen's egg over the upper part of the right occipital area.

#### *COMMERCE IN RADIUM.*

With reference to an article under this heading which appeared on January 7th (p. 19), a correspondent informs us that, besides the known deposits mentioned therein, large deposits of uranium ore are now being developed in the Flinders Range in the Northern Section of South Australia. Extensive lodes of antimony and torbenite, not associated with any other metal or mineral, have been found, and radium element has been extracted from these ores at the Australian Radium Corporation's treatment works at Adelaide.

#### *THE "TRANSPARENT" CARD HINGE.*

The device which now bears this name, and which was formerly called the "M. H. S. Card Clip," is the invention of an English doctor and is manufactured by Messrs. Cooper, Denison, and Walkden, Ltd., St. Bride Street, E.C.4. It is designed to furnish a means of keeping index cards, notably those used in insurance practice, permanently grouped without the use of clumsy wire clips; by its use a number of cards can be quickly attached to one another to form a "book." Each hinge consists of a small double disc of strong light fabric, the two parts being united by a flange of stiteling and the inner surfaces of the discs being gummed, so that the edges of the cards may be fastened firmly between them.

#### *THE PETROL ENGINE.*

In *The Petrol Engine* the staff of the *Motor* provides motorists, mechanics, and others with a brief and clear account of the construction and use of the petrol engine. The descriptions of the various parts of the engine are simple, and the book is well illustrated, so that it is easy for one with no mechanical training to understand the working of his machine, whether it be a touring car, a motor cycle, or a commercial vehicle. The first chapter gives the history of the early development of the internal combustion engine. At the end there is a chapter describing the chief types of engine for petrol-electric lighting sets. The book is a useful addition to the Temple Press series of manuals for motorists. Its price is 3s. 6d.

#### *MOTOR TYRE MANUFACTURE.*

The Dunlop Rubber Company extends to any medical practitioner who is interested in motor tyre equipment an invitation to visit the works and see the manufacture of tyres in progress from the raw rubber to the finished article. Any reader who desires to take advantage of this invitation should communicate with the Reception Officer, Fort Dunlop, Erdington, Birmingham.

#### *VACANCIES.*

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 48, 49, 52, 53, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 50 and 51.

A brief summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 211.

# A British Medical Association Lecture ON IMMUNIZATION AGAINST DIPHTHERIA, SCARLET FEVER, AND MEASLES.\*

DELIVERED TO THE HARROGATE DIVISION ON MARCH 17TH, 1928,

BY

S. MONCKTON COPEMAN, M.D., F.R.C.P., F.R.S.

## DIPHTHERIA.

THE outcome of Behring's researches on diphtheria, resulting in the introduction of antitoxin, constituted a great advance in the treatment of this disease, by affording the possibility of mitigating and even of aborting attacks; provided that the antitoxin is employed at a sufficiently early stage. Moreover, if "contacts" are inoculated before any symptoms have developed, incidence of the disease can be prevented. Unfortunately, however, the passive immunity thus produced is of a very fleeting nature, not extending, as a rule, for a period longer than three weeks or so. Consequently, although of undoubted service in face of an existing outbreak, the inoculated individual will, in all probability, prove just as liable to contract the disease if subsequently exposed to infection.

It is to the work of Schick, first published in 1910, that we owe the introduction of a means of testing for the presence or absence of immunity, and of the method of active immunization against diphtheria, which has put into our hands a means of prevention the value of which has now received recognition throughout the civilized world. In this country work on the lines laid down by Schick was not taken up to any extent for a number of years subsequent to its publication. But in America the case was very different, more especially in New York, where, owing to the enthusiasm of Dr. W. M. Park and of his assistants, Drs. Anna Williams and Abraham Zingher, investigations were initiated at an early date and on an extensive scale.

It was not, however, until 1921, on the occasion of an outbreak of virulent diphtheria in the Southmead Infirmary of the Bristol Union, into the circumstances of which I made inquiry, that official investigation into the potential value of the Schick test and of toxin-antitoxin inoculations in connexion with diphtheria prophylaxis was initiated. Here our first attempt at immunization (on a nurse in one of the diphtheria wards, who, unfortunately, turned out to be a serum reactor) was followed by considerable rise of temperature and malaise on the part of the patient. Happily, however, this case proved to be quite exceptional, and, moreover, we subsequently found that by commencing with a minimal preliminary sensitizing dose of the immunizing mixture the full dose could be given twenty-four hours later, even to adults, in whom reaction is usually more marked than in children, without any similar trouble arising.

An account of what was eventually accomplished at the Southmead Infirmary was set out in the "Report on Diphtheria," published by the Ministry of Health. Suffice it to say that since the work was carried out diphtheria has not again been a source of trouble in the infirmary.

The Schick test is a clinical test by means of which the antitoxic immunity of individuals, and consequently their susceptibility or otherwise to the disease, can be judged by a local skin reaction. Experience has shown that the blood of persons who have recovered from diphtheria, or are otherwise immune to the disease, contains not less than 1/30 unit of antitoxin per cubic centimetre. The amount of toxin used in the Schick test is such as will cause a positive reaction in persons with less than this amount of antitoxin in the blood. The test is carried out by injecting into, but not under, the skin of the flexor surface of the forearm 0.2 c.cm. of a freshly made dilution of standardized diphtheria toxin of full strength. Care must be taken that the needle is inserted into the proper layer of the skin, and in this and other minutiae a certain amount of practice is necessary. As a control, a similar amount of the same

solution, previously heated so as to destroy the toxin, is also injected intradermally on the opposite arm. The results first become apparent after about twenty-four hours, but it is difficult to be certain of an accurate reading before at least ninety-six hours have elapsed.

The reaction appears on the surface of the skin at the site of injection as a positive, a negative, a pseudo, or a combined (positive) reaction.

(a) The positive (susceptible) reaction is indicated by a roughly circular area of a more or less deep red colour around the site of injection, while no change occurs on the control arm. It is due to the irritant effect of the toxin acting upon tissue cells which are not protected by antitoxin. A positive reaction indicates that little or no antitoxin is present in the patient's blood, and that, in consequence, susceptibility to diphtheria exists.

(b) In the negative (immune) reaction there is no change at the site of injection on either arm, and a result of this kind indicates immunity from diphtheria.

(c) In a "pseudo" reaction there is an approximately equal area of redness on both arms, which usually reaches its height in about twenty-four hours, and may have completely faded by the fourth day. The pseudo reaction is non-specific, and occurs in persons susceptible to the action of "foreign" proteins in general; it is to be regarded, equally with the negative reaction, as indicating immunity to diphtheria.

(d) The combined (positive) reaction presents elements of both the positive and the pseudo reaction in the same individual. In this case a reaction occurs in both arms, that on the arm inoculated with potent toxin being larger and usually presenting a distinctly defined, central red area. The pseudo element on both arms disappears early, leaving persistent evidence of the true positive reaction.

Under the auspices of the Ministry of Health Schick-testing, followed by immunization of individuals giving a positive reaction to the test, has now been carried out on about 50,000 children and adults in various "centres," institutions, and secondary schools in this country, with the satisfactory result that, with the exception of two or three specially susceptible cases, none of these children, even when exposed to risk of infection, has subsequently contracted the disease. And whereas, in one of these institutions, limited outbreaks of diphtheria had, for several years, been the cause of much trouble and expense at intervals of a few months only, since the work was completed—with the added precaution of the immunization, when requisite, of further admissions—there has been absolutely no recrudescence of the disease.

In view of the increasing prevalence of diphtheria the suggestion has been made that the education authorities should follow the lead of New York and undertake the testing and immunization by the Schick method of all children of school age. But I would suggest that it is of even more importance to aim at immunization of all children of pre-school age—at the period, that is, of greatest danger, and in order to obviate appreciable risk of contracting the disease when they come in close contact with other children on joining school. This work, until recently, had only been attempted on a comparatively insignificant scale in this country.

Doubtless publication of reports (unfortunately justified) as to certain fatalities which occurred in Austria about a couple of years ago; in some similar instances at a previous date in America, in consequence of the use, for immunization purposes, of batches of toxin-antitoxin mixture subsequently found to contain excess of toxin; and, most recently, in Bunderberg, Queensland, concerning which an authoritative report is still awaited, has somewhat naturally deterred various authorities from advocating and arranging facilities for carrying out the work. However, recurrence of such mishaps is improbable in future, owing to the fact that anatoxin, or toxoid, which is entirely non-poisonous, is now successfully replacing toxin in the immunizing mixture.

In view of the fact that a high percentage of infants over the age of 6 months are likely to be susceptible considerable saving of time and energy can be gained by omission of the preliminary Schick test. Research, moreover, is being directed to the possibility of reducing the

\* This is an abridgement of the lecture, which was illustrated with lantern slides in natural colour photography.

three immunizing doses now required to two, or even one, and also of combining a first immunizing dose with the preliminary test. But, whenever possible, it is most desirable to perform a further Schick test about three months subsequent to the last immunizing inoculation, as it is known that in a few instances the ordinary procedure may not suffice for conferring adequate protection, and so may have to be repeated.

Reduction in the number of inoculations requisite for the attainment of an adequate degree of protection would undoubtedly constitute a valuable advance towards more general acceptance of the method. But even so, opposition is still likely to be encountered, as there undoubtedly exists widespread objection to the adoption of any therapeutic measures involving the use of inoculation methods. Yet it is certain that we have at our disposal, in the immunization of infants and those of school age, a most powerful weapon in our fight against the ravages of diphtheria, but much propaganda work will be essential in this country if the desired end is ever to be attained.

I desire also to advocate most strongly the Schick-testing and, if necessary, the immunization of all nurses employed in fever hospitals before being allowed on duty in diphtheria wards. This, I am glad to know, has been the rule as regards the staff of the Bristol City Hospital, for instance, since January, 1922, with the result that no completely immunized member of the staff has ever developed clinical diphtheria. But, as pointed out by Sir George Newman, "there are still many infectious diseases hospitals where nurses are allowed to attend diphtheria cases without having been offered the advantage of this method of protection." He adds that "one large authority calculated that the total cost to the hospital of every nurse who took diphtheria was £28 10s., while the cost of immunizing a nurse was 2s. 9½d. only."

#### SCARLET FEVER.

During an official visit to New York a few years ago I was afforded opportunity of studying work then in progress on the bacteriology of scarlet fever, on methods of immunization, and on the specific treatment of individuals who had already contracted the disease. The work was, in large measure, concerned with what is known as the "Dick test," so named after its introducers, a test which exhibits many analogies to the "Schick test" for diphtheria.

As the outcome of their study of the bacteriology of scarlet fever the Dicks, apparently confirming earlier results by Klein, Tunnicliffe, Bliss, and Mervyn Gordon, claim that a haemolytic streptococcus, long recognized as a micro-organism constantly present in the nasopharyngeal cavities of patients suffering from scarlet fever, constitutes the probable etiological agent of the disease. But considerable difficulty has been experienced by all who have worked at the subject, owing to the fact that it seemed practically impossible, by the inoculation of the usual laboratory animals, to produce a disease bearing any definite resemblance to scarlet fever. Various observers have shown, however, that by cultivation of the supposedly specific haemolytic streptococcus in blood-broth a toxin can readily be produced inoculation of which in the human subject is said to have caused some of the main features of the natural disease, including the rash. This toxin, suitably diluted, is used for the purpose of the Dick test for determination of the susceptibility or otherwise of individuals to scarlet fever, the test fluid being inoculated intradermally in precisely the same manner as the solution of diphtheria toxin in performance of the Schick test. The results following on the use of this test are also very similar to those observed in the case of the Schick test, except that the reactions appear more rapidly, being at their maximum intensity after an interval of about twenty-four hours, and subsequently fade more quickly.

Further evidence in favour of possible specificity of the toxin is afforded by the fact that its effects can be completely neutralized by admixture with blood serum obtained from a convalescent scarlet fever patient, or with the serum of a horse which has been immunized with the toxin. Furthermore, if serum from either of these sources be injected intradermally into the skin of a patient suffering

from an early scarlet fever rash a blanching of the rash over the area of the injection is produced in the course of six to eight hours subsequently. This phenomenon, of considerable service as an aid in diagnosis, is known as the Schultze-Charlton reaction.

As regards the extent of the reaction following on the Dick test among children not suffering from scarlet fever very similar results to those well known in connexion with the Schick test have been obtained. Thus in the earliest stage of life a child apparently obtains fleeting placental immunity from the mother, so that up to the age of 3 months, at any rate, the Dick test is likely to afford a negative result. At subsequent ages the relative proportion of positive and negative results, as in the case of the Schick test, will develop according to age, to social status, and as to whether the child is town or country bred.

Many thousands of children in hospitals or infant welfare centres in New York, found to give a positive reaction to the Dick test, have now been inoculated intramuscularly with scarlatinal haemolytic streptococcus toxin. As in the case of the Schick work, these inoculations have usually been three in number at weekly intervals. These, in the majority of instances, have not given rise to any undue reaction locally or constitutionally. Again, as in the case of the Schick work, it is important that the results of these inoculations *qua* immunization should be determined by a further Dick test after an interval of three or four months from the last inoculation.

About a couple of years ago the Committee on Scarlet Fever, appointed by the Ministry of Health, decided that it was desirable that intensive investigation into the etiological relationship of certain haemolytic streptococci to this disease, and the diagnostic value of the Dick test, should be undertaken under the co-ordinated direction of a team of expert pathologists and clinicians. With the object of ensuring, as far as possible, that the work carried out in the different laboratories should be on strictly comparable lines it was arranged that similar methods and, so far as possible, identical materials should be employed by all the different workers concerned.

The scheme ultimately adopted has comprised, on the clinical side, performance of the Dick test as a routine measure on all patients notified as suffering from scarlet fever admitted to certain infectious diseases hospitals, together with a further Dick test, when possible, prior to their discharge. On the pathological side, throat discharges of scarlet fever patients admitted to these hospitals have been examined for the presence of haemolytic streptococci, while, for purposes of comparison and control, strains of these micro-organisms of non-scarlatinal origin have also been isolated from various sources, and submitted to thorough investigation in the various laboratories concerned.

It is essential to bear in mind that the problems connected with the diagnosis of scarlet fever, and of immunization against this disease, are, in certain respects at any rate, much more complex than in the case of similar work in connexion with diphtheria. Of primary importance is the necessity for accurate differentiation of the specific micro-organisms responsible for the production of the disease in susceptible individuals. The departmental sub-committee has lately arrived at the conclusion that a haemolytic streptococcus is to be regarded as the responsible agent; but the variety of strains that have been isolated from the throats of patients suffering from this disease renders it difficult, as yet, to determine precisely whether one particular strain, or any of several varying strains, are specially concerned. Again, the divergent results not infrequently met with in connexion with the classification of haemolytic streptococci by agglutination and absorption tests introduce further difficulties.

An interesting point, to which sufficient attention has hardly perhaps hitherto been paid, concerns the nature of the population which it is sought to immunize *qua* degree of susceptibility as estimated by means of the intradermal test. Experience has clearly indicated, in the case of our work on diphtheria, that where a certain general basis of immunity already exists it is comparatively easy to increase the extent of this immunity to a sufficiently high level. On the other hand, in certain

institutions which for years previously had been completely free from this disease, probably owing to the fact that most of the children are recruited from unaffected rural districts, we found that immunity was practically non-existent. And so, unfortunately, the building up of a sufficient degree of immunity proved a matter of no little difficulty, requiring indeed, as eventually became evident, a time interval more lengthy than previously observed. It remains to be seen whether the response to immunization work in scarlet fever will be found to run on similar lines. It is, I think, as yet hardly possible to estimate what may eventually prove to be its precise value as compared with immunization against diphtheria. As a matter of fact, so far as is at present known, attainment of anything like complete immunity by means of inoculation methods appears to be decidedly more difficult of accomplishment in scarlet fever than is the case with diphtheria. Moreover, there is, unfortunately, reason for believing that immunity thus produced is by no means permanent.

#### MEASLES.

As in diphtheria and scarlet fever, so also in the case of measles, infants appear to inherit some temporary immunity from their mothers, which is said to last until the fifth or sixth month of extruterine life. From this period onwards, however, up to the age of 5 years, mortality from measles is high (from 13 to 15 per cent.), mainly owing to its complications—a fact which renders desirable some more effective method than “the careful nursing of each case” which at present, as we are told, constitutes “the only possible way of reducing its mortality.” It is therefore of interest to realize that a method of immunization has been worked out recently which has been reported by many observers to be of value in this connexion. The method consists, in its original form, of the subcutaneous administration of small doses of serum obtained from patients recently convalescent from the disease. If required, advantage may be taken of the fact that antibodies are also present, although in smaller quantity, in the serum of adults who have had measles.

It is of interest to note that as long ago as the year 1758 Francis Home of Edinburgh introduced a method of active immunization against measles which had been suggested by Alexander Monro in the previous year. About forty years ago Hugh Thompson, a vaccinator appointed by the Faculty of Physicians and Surgeons of Glasgow, devised a method of blistering measles convalescents and vaccinating contacts with the serum, for which he claimed good results. In this connexion, as in so many others, it is curious to note how history has a habit of repeating itself, as illustrated by the fact that only last year Professor Karl Leiner of Vienna introduced a similar method, the employment of which, however, he discontinued in consequence of a campaign of opposition from the daily press.

As in the case of scarlet fever, progress in regard to immunization against measles has been greatly hampered owing to want of knowledge as regards the specific virus of measles, although various micro-organisms have been incriminated from time to time. But, pending more definite knowledge as to the bacteriology of measles, the method of immunization by means of “convalescent serum” to which I have already referred is obviously one which demands our serious consideration. This was first employed by Nicollo and Conseil during a small epidemic of measles in Tunis in 1916, and has subsequently been employed extensively by Park and Zingher and by Richardson and Connor in America, by Degkwitz in Munich, and by Debré in Paris. Various workers have since modified the original methods of Nicollo and Conseil, and the production of active immunity has been attempted, apparently with some measure of success.

To achieve passive immunity the following methods of employing the serum are feasible: (1) Injection of convalescent serum into healthy contacts; in this case an immunity which lasts about a month is produced. (2) Injection during the first five or six days of the incubation period, when, as Degkwitz and others have shown, the patient will not develop measles; although the later it is injected the larger will have to be the dose.

If the serum be injected *after the sixth and before the ninth day*, measles will, nevertheless, develop; but the attack will be modified in the length of its invasion period, and by the absence of catarrhal symptoms, Koplik spots, and high temperature. The eruption also, if present, is less confluent, and the macules are smaller.

Injection at the beginning of the period of invasion (about the tenth day) will result only in local inhibition of the rash—the phenomenon of Debré—as regards which it should perhaps be mentioned that it is not, as has been suggested, comparable with the Schultz-Charlton reaction in scarlet fever.

With regard to the production of active immunity, besides the method mentioned of inducing a modified attack, Nicolle has suggested that the child it is desired to protect be given 10 c.cm. of convalescent serum, and, twenty-four hours later, 1 c.cm. of blood from an early case of measles. If the injection of blood be repeated, it is stated that the immunity produced is likely to be permanent. This method is probably reproduced in Nature when serum is given to a very early case.

The results obtained by the majority of workers who have used the earlier methods referred to have been decidedly favourable, as, indeed, is evidenced by the fact that municipal collecting and distributing centres for the serum have been established in connexion with hospitals in Germany, France, and America.

No original work on the subject had been published in this country prior to a paper by Dr. W. S. C. Copeman,<sup>1</sup> recording successful results obtained by him in face of a somewhat exceptionally severe epidemic of the disease which prevailed during the period February to July, 1925, at the Children's Hospital in Paris; and it will be of interest to members of the Harrogate Division to recall the fact that Drs. Smith and Miller, working on similar lines, recorded some successful results in a communication to the Pathological Society of Great Britain and Ireland in January, 1927.

In view of the importance of lessening, if possible, the mortality from measles in this country, we shall doubtless all agree that it is eminently desirable that investigation of the whole subject should be officially undertaken as speedily as possible, perhaps somewhat on the lines of that recently initiated in connexion with the work of the departmental committee on scarlet fever.

Meanwhile, it is encouraging to learn from Sir George Newman that the Ministry of Health, in conjunction with the Medical Research Council, is maintaining close observation upon the important investigations of Dr. Degkwitz, especially concerning the use of a sheep serum introduced by him, and the prophylaxis of measles generally.

## FUNGUS INFECTIONS OF THE HANDS AND FEET.

BY

RUPERT HALLAM, M.D.,

HONORARY PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT,  
THE ROYAL INFIRMARY, SHEFFIELD.

THE diseases to which I wish to draw attention are deeply situated in the epidermis and are very refractory to treatment. Many varieties of fungi may be pathogenic and provoke changes in the skin. Their classification is complicated, but broadly they may be divided into (1) the ringworms (*Gymnosaceae*), (2) the yeasts (*Saccharomyces*), and (3) some members of the order *Hyphomycetes* such as *monilia*. The reactions of the skin may be to all appearances identical, and the same species of fungus is able to produce lesions which differ clinically. The subject is still further complicated because many moulds and fungi are saprophytic, occurring on normal skin without producing any reaction, but both the yeasts and the ringworm mycelia have been found consistently invading the layers of the epidermis in the same type of skin lesion; in addition, the lesions have also been produced successfully by rubbing

the culture growth into scarified skin. Experimental work in this branch of dermatology is limited, for animals have a high degree of immunity to some of the species. Koeb's postulate is therefore difficult to verify; but there is sufficient evidence that certain forms of skin disease are the response of the skin to the action of fungi which are pathogenic. Clinically they may be divided into (1) infection of the interdigital clefts; (2) acute vesicular eruption of the hands and feet; (3) infection of the nails.

#### *Infection of the Interdigital Clefts.*

In many patients the fungus responsible is the epidermophyton; this is the same parasite which attacks the upper third of the thigh and the groins, and causes the so-called *dhobi itch* or *tingea cruris*. It was first described clinically by Hebra under the name of "*eczema marginatum*" so long ago as 1860. Afterwards the parasitic nature of the malady was recognized, but it was not until fifty years later that Whitfield<sup>1</sup> in this country, and Sabouraud in France, called attention to parasitic lesions occurring on the feet, which were shown by Sabouraud to be due to the same fungus as the circular or polycyclic lesions of the groin.

Sabouraud's classic studies of the cultural characteristics of the pathogenic fungi known at that time established on a sound basis the importance of these diseases and led to an immense amount of research. It has since been proved that it is possible for the fungous elements to be carried by the blood stream, and to give rise to a generalized rash polymorphic in character (Arzt and Fuchs,<sup>2</sup> Ambrosoli<sup>3</sup>). In 1918 V. Graffenried<sup>4</sup> successfully inoculated two human subjects with the epidermophyton. Bloch<sup>5</sup> had previously shown that these fungi had the property of producing an allergic or sensitized state of the skin, but not always an immunity in the true sense of the word. He infected himself with the trichophyton and afterwards grafted a piece of his skin on to a patient suffering from a leg ulcer; the grafted skin alone was shown to be sensitized to the toxin of the fungus, thus demonstrating that the sensitiveness is a cellular phenomenon.

Some individuals are more susceptible than others, and it is not uncommon for one partner of a marriage to remain free from the infection although the other has suffered from it for many years. We must note also that different fungi have a predilection for various parts of the body. The interdigital infection, whether it be due to the epidermophyton or other fungus, may be present for years without the patient experiencing anything more than an occasional slight discomfort; yet it may flare up suddenly and rapidly spread to the axilla, the gluteal cleft, the submammary folds, and elsewhere, not only causing considerable distress, but incapacitating the patient from following his or her occupation.

In an overwhelming proportion of the patients the disease is first noticed in the interspace between the fourth and fifth toes of one or both feet. If the toes are separated a white macerated epidermis is observed, which can be detached by forceps; small vesicles may be present at the edge or under the sodden skin, and not infrequently a fissure is to be found at the apex of the cleft. If the macerated skin is removed the exposed surface is seen to be of a bright red colour. The same condition may be present between all the toes, or may be limited to one or more clefts on one foot for years. In many cases if the plantar surface of the infected toes is examined it will be seen that this too is infected and fissured. The disease is inclined to spread along the sole, causing eczematous lesions together with increased cornification and painful fissuring. In addition, a dermatitis of the anterior surface of the legs is often present, and also in the hands one or both palms will sometimes be found to be fissured. It should be noted that the infection may occur on the instep without the toes being involved. As already stated, the axillae and groins may be affected, giving rise to circular or polycyclic patches of red inflamed skin. The following cases serve to illustrate the above description.

A married woman suffered from solid oedema of both ears and post-auricular fissures, with maceration and inflammation of the skin of the upper gluteal cleft. Maceration and fissures occurred between the toes of both feet, and mycelia were found in the

epidermic scales from between the toes. The patient had been aware of the cracks between the toes for six years; the other lesions had been present for two years, and were thought to be *seborrhoeic eczema*.

A man complained of pruritus ani of ten years' duration. He had had various treatments, including innumerable ointments, ultra-violet light, and x rays. Examination revealed extensive dermatitis of the perineum and buttocks, with the characteristic fissures between all the toes. Mycelia were present in the scales from the toes. The patient stated that the toes had been sore for more than ten years, and that the complaint was thought to be a manifestation of gout.

Two patients had dermatitis on the forehead and the upper lids, together with mycosis of the toes, verified by microscopical examination.

With reference to the second patient mentioned, it is interesting to note that A. Castellani<sup>6</sup> drew attention to the fact that pruritus ani might be associated with a fungous infection. He found either the epidermophyton or trichophyton present in 11 out of the 54 cases he examined. Some of the skin complications are probably due to sensitization phenomena, and are not caused by the local growth of the fungous elements; for although it is possible to recover the fungus from the accompanying lesions between the toes, repeated examination fails to find it in other situations.

There is no doubt that the disease is more common in the middle classes than among the manual workers, and in my experience during the war groin ringworm was more frequently met with among the officers than amongst the men. Outbreaks of a serious nature have occurred in some public schools. The incidence is relatively high among young men; this is probably explained by the infection taking place through the medium of bathroom floors, towels, etc. Experiments show that the epidermophyton will live for at least a year in a dry state, and it has been recovered from infected boots four months after they were discarded. The incubation period is thought to be about twelve days.

Microscopical examination is essential for establishing the diagnosis, and may have to be repeated several times before the true nature of the disease is detected. The actual technique is simple, but requires some practice before the mycelia can be recognized. Epidermic scrapings should be taken preferably from the edge of the toe lesion, tamped in liquor potassae, and then examined with a 1/6 in. objective. The mycelia are long, slender, highly refractile threads. Exact identification can only be achieved by culture on special media, but description of this process is outside the scope of this paper.

Treatment to be successful necessitates meticulous care on the part of the patient and his medical attendant. This is easily comprehensible when it is realized that the fungus occurs deep in the epidermis, is buried in all the nooks and crannies around the nails, is hidden in socks and boots, and in many cases is found to be growing in the nail substance itself. It is very resistant to moist heat, but according to Schanberg and Kolmer<sup>7</sup> is killed when boiled for ten minutes. The same authors found that the epidermophyton is also easily destroyed by weak antiseptics.

Unfortunately it is no easy task to destroy these fungi in the living subject. In order to do so the exfoliating sodden epidermis must be thoroughly removed daily with a curette, and the toenails must be pared and scraped. As it is difficult for the average patient to perform the contortions necessary, it is advisable that this part of the treatment should be allotted to a third person.

There is a wide choice of remedial applications, the most noted of which is an ointment recommended by Whitfield, which now has a world-wide reputation. It consists of benzoic acid 5 per cent., salicylic acid 3 per cent., in a base of coco-nut oil and vaseline. Although the fungicidal property of the ingredients does not appear to be very high, yet in many of the cases an application of the ointment brings about a rapid improvement. Other remedies are tincture of iodine diluted with ten volumes of spirit, a 2 per cent. aqueous solution of mercurochrome-220, and 5 per cent. chrysorbin ointment. In my experience the first and the last named are the most serviceable, but whichever is chosen will fail unless the preliminary cleansing is carried out with exacting care. The feet should be washed daily. Socks should be of cotton, and

boiled for ten minutes daily; boots and shoes require dusting inside with an antiseptic powder such as boric acid. The treatment should be continued for at least a month after all signs of the disease have disappeared, and infected boots and clothing should then be destroyed. Surrounding dermatitis of the feet, if present, should be treated by the same remedies, but a fractional dose of x rays will greatly assist in its disappearance.

In 1903 Ciarocchi<sup>8</sup> described a dermatitis limited to the webs of the fingers; this closely resembles in appearance the affection in the clefts of the toes mentioned above, but it is caused by other species of fungus—*monilia* or a member of the yeast group. It is curiously selective in position, for in the majority of patients its habitat is the web between the ring and middle fingers, although other webs may be involved. It is much less common than the mycosis of the toes, and so far has only been met with in women, most of whom have an occupation necessitating the frequent immersion of the hands in water. Kaufmann-Wolf<sup>9</sup> produced similar lesions of her own hand with a culture from a patient with the disease. This disease is refractory and should be treated on the same lines as the mycosis of the toes.

Such patients are usually of the hospital class, attending for the first time. They are often in a pitiable state; the hands are bathed in pus, under which is a dirty sodden skin, buttonholed in numerous places by the rupture of some of the pustules. It is astonishing how rapidly these patients improve if all the dead overhanging epidermis is removed daily, and a wet dressing of 1 per cent. solution of silver nitrate is applied three or four times a day. The oedema disappears, fissures heal, and, although the skin is covered with the black stain of silver oxide, it is soon apparent that the disease is under control. At this stage a fractional x-ray exposure materially hastens recovery. If the patient is spared the pyogenic infection, the vesicles dry and the skin exfoliates in about fourteen days. In such a case a protection by boiled cotton gloves or sterile gauze will suffice.

A girl, aged 10, was admitted to Sheffield Royal Infirmary suffering from vesicular eruption on all her toes. A pure yeast culture was obtained from the vesicles on three successive examinations. This case is interesting as she had previously been admitted to Firvale Hospital for the same complaint. A few weeks later she was discharged quite healed; but the vesicles returned within a few days—reinfection from her boots probably accounted for the recurrence.

Vesicular eruption on toes. A pure yeast culture was obtained from the vesicles.

Paronychia of the fingers and thumb. Culture showed growth of a cryptococcus.

#### *Cheirpompholyx.*

The cheirpompholyx of Hutchinson or the dysidrosis of Tilbury Fox has recently been the subject of research and discussion, and the consensus of opinion is that this vesicular eruption of the hands should in no small proportion of cases be regarded as a mycosis. Kaufmann-Wolf demonstrated a fungus in the vesicles in 30 per cent. of her cases. Darier<sup>10</sup> stated that, excluding trauma and pyogenic infections, most cases (80 per cent.) were of mycotic origin. I have made a practice of examining the cases occurring in this district, and have found mycelia present in comparatively few. It is likely, however, that a more prolonged search would reveal a larger percentage of positive cases. The trichophyton appears to be the most frequent aggressor, but members of the yeast group are also responsible. The complaint is prone to recur, and is most common in young people, particularly women.

Although the hands suffer more frequently than the feet, it is by no means unusual to find vesicles in both situations during the same attack. The eruption is preceded by burning and itching. Small deeply situated vesicles then appear, the favourite position being the borders of the fingers and the palms. It is almost invariably symmetrical, and, should it be present on the feet, the vesicles are less numerous than on the hands. As the vesicles are deeply situated they do not rupture easily, but they may be secondarily infected, when they increase in size, coalesce, and rupture. Oedema of the hands accompanied by lymphangitis and pain is a further complication. Unless the pustules are incised and the whole of the exfoliating epidermis removed, the pus tends to burrow under the surrounding epidermis.

#### *Fungus Infection of the Nails.*

Trichophyton infection of the nails has been recognized for many years. It may be present without any other manifestation of the disease, or may be associated with an affection of the beard or any other part of the body. Recently, however, cases have been described in England and abroad which are due to a yeast—*Oospora* (*Oidium*) *albicans* (Avid Scott,<sup>11</sup> Shelmire,<sup>12</sup> Kumer<sup>13</sup>).

When the disease is confined to the nail itself it commences at the free border, which becomes irregular, brittle, and of a dirty grey colour. This change gradually extends towards the lunula. In certain cases, and particularly when the "thrush fungus" is responsible, the changes in the nail are accompanied by paronychia. The appearance is then as follows: The soft tissue bordering the nail is oedematous, red, and raised. When gently massaged a sero-purulent fluid may be pressed from under the margins. There is often some crusting at the bottom of the nails, and if this be removed the nail fold is found to be detached from the nail. The free margin of the nail is raised by a brownish-grey debris. It is at first localized to one nail, but after varying intervals others are involved. The hands are more commonly affected than the feet. Changes in the nails which closely resemble the above are met with as an accompaniment of other diseases, or may be due to infection with staphylococcus or *B. coli* (H. MacCormac<sup>14</sup>), but careful microscopical and cultural examinations reveal an invading fungus in an increasing proportion of cases examined.

The treatment of the affliction is difficult, whichever variety of fungus is concerned. Perhaps the most successful procedure is avulsion of the nails, but even this drastic

remedy cannot always be relied upon to accomplish the desired result, for a recurrence may follow when the nail grows again. A more simple method is to pare and scrape the nails to the utmost limit of the patient's endurance, and then apply a 2 per cent. solution of silver nitrate or Fehling's solution. It is essential to keep the fingers dry, for the disease is most common in those whose occupation entails the immersion of the hands in water. It is also advisable to continue the treatment with a weaker solution after the disease is apparently cured.

In conclusion, I would emphasize the point that these diseases are more common than is generally supposed; they are of sufficient medical and social importance to deserve recognition and study by medical practitioners.

## Report

ON

THE TREATMENT OF MALIGNANT DISEASE BY  
COLLOIDAL LEAD.

BY

STANLEY WYARD, M.D., M.R.C.P.,  
ASSISTANT PHYSICIAN TO THE CANCER HOSPITAL, LONDON.

IN view of the success claimed in the treatment of malignant disease by means of injections of colloidal lead I visited Liverpool in April, 1926, and, with Professor Blair Bell's permission, saw some of the patients who had there been submitted to the treatment, and observed the technique of the process. Although I was unimpressed by the results which were shown it was considered necessary by the Cancer Hospital that the method should be fully investigated. Dr. Lorna King was therefore appointed to assist me, and together we have treated a total of 88 patients in this way. Of these, however, 32 were given a preparation of colloidal lead hydroxide, and I omit details of them for three reasons—namely: (1) the preparation differs from that used by Professor Blair Bell in that all the lead has been converted to hydroxide, whereas in the latter only a variable and unknown proportion is in that form; (2) it is extremely toxic—ill effects so frequently follow its use, and are so marked, that I consider its employment unjustified; (3) no evidence of benefit was obtained in any case. Moreover, it has often been emphasized that satisfactory results could be obtained only if the lead be prepared in a particular manner, and if its pharmacological effects be closely watched in each patient. That much importance need be attached to such a statement is more than doubtful—the method used in Liverpool for preparing the metal has been many times changed, and there is no evidence whatever that one method is more successful therapeutically than another—but it was obvious that, in the first place, the original technique must be strictly followed.

Fifty-six cases were treated strictly by the Liverpool method—namely, 35 at the Cancer Hospital, 18 at St. James's Hospital, S.W., and 3 privately. In describing the results no differentiation is made between these series.

## Method of Preparing the Colloidal Lead.

When this work was commenced it was impossible to obtain colloidal lead except by preparing it for oneself. The necessary apparatus was erected by Mr. C. E. Phillips, consulting physicist to the Cancer Hospital, and consisted essentially of a circuit containing a voltmeter and an ammeter together with an adjustable resistance, such that a current of 70 volts and 10 amperes passed when an arc was established between two pure lead electrodes immersed in distilled water. The water was placed in a porcelain

bowl with a few small lead shot. One electrode was then fastened so that its lower end was in contact with the shot, which were constantly stirred with the other electrode while the current passed. In twenty minutes a colloid suspension of lead (about 0.5 per cent.) was obtained. Its concentration was estimated by a modification of Nesler's method—a not very accurate one for such quantities, but the most practicable in the circumstances. For use, the suspension was diluted to exactly 0.5 per cent., and 0.4 per cent. gelatin, 2 per cent. sodium chloride, 0.05 per cent. potassium chloride, and 0.027 per cent. calcium chloride were added. The preparation is very unstable, sedimentation quickly occurs, and oxygen is rapidly absorbed from the air with the formation of very toxic lead hydroxide. It must consequently be used at once, and cannot be prepared in bulk for use at a later date.

From time to time certain slight modifications were made: First, 4.0 per cent. of gelatin was added instead of 0.4 per cent., so that the preparation was solid at ordinary temperatures. In this condition it could be stored in sealed ampoules, and remained stable for several months. Then iso-electric gelatin was substituted for the ordinary substance, and had the same stabilizing effect without becoming solid. Sometimes a trace of a reducing agent was added to hinder the formation of hydroxide. Finally, we reverted to the original preparation.

All these preparations are essentially the same, and there is no reason to suppose that their therapeutic action differs.

## Type of Patient Treated.

Most types of malignant disease have been treated—epithelioma, carcinoma, and sarcoma. In every case the disease was inoperable when first seen, or was recurrent after operation. Many of them were in an advanced stage of the disease. To obtain suitable patients for such work is far more difficult than appears on the face of it. A large majority of the inoperable patients admitted to hospital are having, or have had, some other form of treatment (for example, radiation), and are therefore unsuitable for this, since any change observed could not be certainly attributed to either method. If the patient be not already under some form of treatment he or she is generally too near the end for any form. Another difficulty is that very often the patient refuses to remain long enough in hospital to give the method a chance. No patient in this series had received any but surgical treatment.

## Dosage.

In deciding on the dose to be given an attempt was made to give the maximum amount of lead which did not endanger life, and to keep the patient as long as possible under the influence of this quantity. With six exceptions the initial dose was 0.08 to 0.1 gram. In one case this was repeated after seven days, with the result that the patient became very ill; there were several rigors, repeated vomiting, and marked jaundice. From these effects she eventually recovered, and survived about seven months, but it was not considered justifiable in any other case to repeat the dose at so short an interval. In seven cases the second dose was given a fortnight after the first, but again the reaction which followed was generally intense, so intense that it was decided to allow an even longer interval. In six cases an initial dose of 0.05 gram was given, and repeated in approximately a week. While these showed no better therapeutic results than the others, the reaction following each injection was reduced to a minimum, and never amounted to much. For the remainder an initial dose of 0.1 gram was followed by the same dose at the end of three weeks. Even after this interval some reaction was almost invariable, but was in no case serious.

Subsequent doses must depend, both as to the quantity and interval, upon the reaction of the individual patient. Our aim has been to administer a total of 0.6 gram to each patient, and we commenced by repeating the original dose of 0.1 gram at intervals of three weeks to six doses. This proved disastrous, for the only two patients who were so treated (one with five and the other with six doses) both died of uraemia within eleven days of the last dose. We therefore changed the procedure and gave three doses of 0.1 gram at intervals of three weeks, and then continued

with doses of 0.05 gram at intervals varying from a fortnight to a month, according to the condition of the patient, and no other instance of renal complications clinically discoverable was encountered amongst those who received the latter doses.

The two cases mentioned above called attention to the importance of determining, if possible, how near one has approached to the patient's tolerance. But no method of doing so was discovered. In both cases, before the last dose, the urinary urea was adequate, the blood urea was well within normal limits, there was no marked anaemia nor deficiency of haemoglobin, and little or no punctate basophilia in the erythrocytes. Lead is, of course, a cumulative poison, and it seems as though it accumulates up to a point without causing any appreciable damage to the kidneys, but immediately that point is passed there is a sudden or rapid destruction of certain of the renal elements, so that the urinary urea falls, the blood urea rises, and the patient becomes uraemic. In one of these cases the blood urea was steady between 18 and 36 mg. per 100 c.c.m., but four days after the last injection it had risen to 146; in the other it was 28 to 34 until the last dose, whereas two days later it was 77, and another five days later 111.

Observations were made on certain of the cases with phenolsulphonethylphthalein, as well as on the various nitrogenous constituents of the blood—for example, uric acid, creatinine, etc.—with the object of determining whether any change could thereby be discovered which would indicate damage to the kidneys before evidence was afforded by the urine or blood urea. No significant change was found, nor did any other case of uraemia occur (though one other patient had died of this condition after a comparatively small dose of lead before these observations were commenced).

Probably the best method of deciding whether, and when, another dose shall be given is by clinical experience. The patient's colour is important—too marked pallor contraindicates immediate treatment. A very severe reaction suggests a longer interval. A reaction, even though moderate or slight, if long drawn out, calls for delay in administration of the next dose. Examination of the blood really helps very little. There is a more or less marked fall of haemoglobin within a few hours of each injection, but as a rule recovery takes place. If the haemoglobin falls very much, or if it fails to recover its previous figure, treatment must be discontinued or delayed. We found that the number of red cells showing punctate basophilia was no evidence whatever for or against continuation of treatment.

#### *Immediate Reaction.*

Following the injection there is usually some general reaction, but very rarely does it amount to much. It is either of two main types: (1) rise of temperature and pulse frequency, rigor, generalized pains (head, back, and limbs); (2) nausea, diarrhoea and vomiting, and abdominal pains. It may come on in a few minutes or be delayed for two or three hours. A sensation of chilliness without actual shivering is the commonest reaction, though not infrequently there is a slight rigor. Both of these symptoms remain but a short time, and as a rule pass off within ten to sixty minutes. Occasionally there is no rise of temperature, more often it rises to about 100° F., in a few cases it will reach 103° F. or thereabout; but 100° to 101° F. is usual. There may be a feeling of malaise—the sensation is apparently indescribable; there may or may not be some headache. Nausea is commonly experienced. Abdominal pain and discomfort were observed once or twice, and definite colic once. Abdominal symptoms may be accompanied by diarrhoea. Only three times was a severe reaction seen—temperature 102° to 103° F., dyspnoea, cyanosis, a small frequent pulse, and pain in the head and back. In only two cases was there any local reaction, shown by swelling and pain in the growth.

In some cases the types have been combined. Recovery was quick and appears complete from the first type of reaction. In the second type the patient felt ill for a considerable time—in two cases the abdominal discomfort lasted for five weeks, and in one of these was followed by a blue line on the gums, a metallic taste in the mouth,

and sluggish knee-jerks. Both eventually recovered, and treatment was continued. In no case has death occurred as an immediate result of an injection of lead.

Occasionally a prolonged reaction was observed. Slight headache commenced an hour or two after the injection, but disappeared after a night's rest. In the morning, however, there was slight nausea, and the patient might even vomit. This condition of discomfort—there is an indefinable feeling of malaise, a suspicion of nausea, loss of appetite—may persist and only pass off in six or seven days.

It is quite impossible to foretell the occurrence of a reaction; it is no more likely after a first than after any subsequent injection.

#### *Late Reaction.*

Rarely was there any apparent effect upon the growth itself—there was no swelling of the mass, no increase of pain in it, and no breaking down; but in two cases swelling of the growth, and pain in it, were noted. It is difficult to say whether these effects were the direct result of lead, or merely that of the natural progress of the disease.

*Effect on the Blood.*—Some degree of anaemia generally follows the injections, though the effect on the erythrocytes is not extreme. The number of the latter falls, often considerably, but rarely below 3.5 million. Even after considerable doses of lead they may remain well up (5 to 5.5 million). A more marked effect is exerted upon the haemoglobin, which falls more rapidly and to a greater extent. In spite of this, only once had we to cease treatment on account of the condition of the blood. Stippling of the red cells was found to a greater or less extent in all cases, but appeared to have no special significance from a prognostic point of view, and after a short time little or no importance was attached to this finding. The white cells did not appear to be affected in any way. Except in one case, when a carcinoma of the breast was complicated by diabetes, the injection of lead did not influence the sugar content of the blood. In the diabetic, however, it seemed to increase the circulating sugar and exert an adverse influence on the course of the disease. Three cases of uraemia have already been mentioned; in no other case was clinical evidence of renal damage obtained—the urine remained normal and the blood urea showed no significant change. In a few cases the excretion of phenolsulphonethylphthalein was tested, but no abnormality was found. In some others the nitrogenous constituents of the blood, other than urea, were also estimated, but without demonstrating any pathological change.

*Effect on the Urine.*—The urine in non-fatal cases has shown variable alterations. In many cases the amount excreted in twenty-four hours has been very much diminished for seven to fourteen days after an injection, usually (but not always) with diminished urea excretion. Cases with reduced urea excretion (even though this be marked) have shown no clinical signs of renal incompetence, have had no rise of blood urea, and have had further injections of lead without ill effect.

*Uraemia.*—Three cases of uraemia occurred. One of these must certainly be attributed to the direct effect of treatment, and is, indeed, a case of acute lead poisoning. This patient received in all 0.6 gram of lead in the course of three months, and eleven days after the last injection she died presenting the typical picture of uraemia. Towards the end the excretion of urine diminished, albumin (at first a trace, later in considerable quantity) and casts appeared in it, and the blood urea rose from 0.034 to 0.111 per cent. At autopsy the kidneys showed well-marked changes in the tubules, but none in the glomeruli. It is more than doubtful whether the other two can be attributed in any way to the lead administered. In one the original lesion was a carcinoma of the cervix, which eventually penetrated the bladder and involved both ureters. The blood urea rose from 0.036 to 0.146 per cent. At necropsy the pelvis of each kidney was dilated, and the kidneys showed numerous minute abscesses scattered throughout. The other died of uraemia after a total of 0.25 gram of lead. A carcinoma of the rectum had been excised some time previously, but a local recurrence appeared and, spreading to the bladder, involved both

ureters. The kidneys showed extensive interstitial fibrosis with tubular changes superimposed. In both these cases ureteric obstruction and subsequent bacterial invasion of the organs are sufficient to account for the microscopic lesions.

No case of typical chronic lead poisoning occurred—constipation, colic, peripheral neuritis, encephalopathy, were never seen—but one patient presented a blue lead line on the gums after 0.25 gram of lead given during a period of eleven weeks.

Autopsies were made on 17 of those who died, and the *post-mortem* findings were remarkably constant. In no case was any sign of regression observed in the growth. In some cases it showed advanced degeneration (but no central

(a) This patient also had diabetes. (b) Died of haematemesis. (c) Left hospital at own request. (d) Still under treatment. (e) Refused further treatment.

necrosis, and no change which is not commonly seen when no lead at all has been given), in others there was no degeneration whatever, and in every case the mass of growth was larger than when treatment commenced. In nearly every instance the brain, liver, and kidneys showed evidence of damage as follows. In the brain there was extreme superficial (subarachnoid) oedema, with free fluid at the base. The choroid plexuses were markedly oedematous. The liver showed extreme fatty degeneration. Apart from the cases of uraemia, the kidneys showed no macroscopic change. In most the cells of the convoluted tubules stained badly and showed some degree of desquamation, but it is possible that this is largely, if not entirely, a *post-mortem* process. But the localization of the changes is noteworthy: in no case was any abnormality discovered in the glomeruli or the cells of the loop of Henle or the collecting and straight tubules. In view of the fact that these appearances are not such as are met with in cases of malignant disease treated by other methods it is fair to presume that they directly result from the toxic action of the lead preparation employed.

#### Final Results.

Of the 56 patients treated one only—with a small supra-clavicular gland which appeared one year after amputation of the breast for carcinoma—showed definite improvement, the gland being now only just palpable, whereas before it was about the size of an almond, and quite visible. Although clinically a definite diagnosis of secondary malignant disease was made, there is no proof that the gland was in fact malignant.

No appreciable change took place in 12, but of these 7 received admittedly inadequate treatment—2 because they were so ill that it was decided to leave them in peace, 5 because they refused further injections. Five received from 0.3 to 0.6 gram of lead in all, but the local condition remained unchanged. Another 11 were actually worse after treatment, of whom 2 received less than 0.3 gram of lead in all (one was considered too ill to receive more, the other refused). Nine received from 0.3 to 0.6 gram, in spite of which the malignant growth progressed. Thirty-two died, of whom 8 had received only one injection each. In other words, of 40 patients who received sufficient lead to warrant the expectation of some benefit, if any ever occurs, 22 died, 11 were clearly worse, 6 showed no change in either direction, and only one in any way improved. (Full results, with total dosage, are given in the accompanying table.)

#### Conclusion.

Of 40 patients who have received 0.2 gram or more of colloidal lead intravenously, only one has shown any improvement, while the majority are dead or obviously much worse than before treatment. So far, then, as my observations go there is no support for the statement that colloidal lead exerts a beneficial influence upon the progress of a malignant growth. Moreover, it is certainly a difficult and dangerous therapeutic method.

## SYPHILIS OF THE HEART.

BY

I. HARRIS, M.D.,

HONORARY PHYSICIAN, LIVERPOOL HEART HOSPITAL.

It is of the utmost importance to recognize syphilis of the heart, this being one of the few heart affections which almost invariably yield to treatment. In many cases, it is true, the improvement due to antisyphilitic treatment is not pronounced, but there are doubtless numerous cases of cardiac syphilis in which proper treatment has effected a complete cure. To overlook a case of syphilis may mean the whole difference between normal health and permanent disability, and sometimes even between life and death.

The incidence of syphilis in heart disease has been greatly underestimated in the past, and there are but scant references to it in the older textbooks. Mackenzie,<sup>1</sup> for instance, dismisses it with a few words, and authors like Romberg<sup>2</sup> actually express the opinion that syphilis of the heart is rare. As a matter of fact syphilis is a

very common cardiac affection, but unfortunately in the majority of cases it is not recognized.

This paper is based on a hundred cases of syphilis of the heart taken from patients attending the Heart Hospital; they represent about 9 per cent. of all cases at this institution.

It is obvious that patients with straightforward syphilis do not attend heart hospitals. The incidence of cardiac syphilis in patients attending venereal disease clinics must be considerable, and no doubt a good percentage of neuro-syphilitics have damaged hearts. Syphilis of the heart must therefore be a common affection. In the great majority of the cases the true character of the disease was recognized in the first instance at the Heart Hospital, although many of these people were attending other institutions and some had been seen by prominent consultant physicians. Obviously the diagnosis of syphilis of the heart is very difficult.

At the outset it is well to recognize that there is not one single method, taken by itself, on which we may rely absolutely for the diagnosis of cardiac syphilis. In order to make a reasonably certain diagnosis of cardiac syphilis it is essential to employ all procedures available for the investigation of the disease; a single method cannot absolutely be relied on, but employed in conjunction with other methods, the evidence of cardiac syphilis may be so strong as to amount to a certainty.

The methods used are the Wassermann test, examination of the physical signs, electro-cardiographic investigation, study of the symptoms and history, and the use of anti-specific treatment.

#### *The Wassermann Test.*

We depend a great deal on this test, but it is not absolutely reliable; two specimens from the same patient sent to different laboratories will sometimes give contradictory results, owing in some instances to inaccuracy, and in others to difference in the methods employed. Moreover, even in this country, as is well known, a positive Wassermann reaction does not invariably denote syphilis; it is believed that tuberculosis and infective endocarditis may, in the absence of syphilis, give rise to a positive reaction; it must also be borne in mind that a positive reaction may indicate only congenital syphilis. We actually have an instance of a positive Wassermann reaction in a grandchild and a grandmother, and numerous cases of members of a family with such reactions which can only be explained by the hereditary factor. On the other hand, a negative result does not mean that the patient is free from syphilis. There seems to be a general consensus of opinion that in the second stage of syphilis a positive reaction is the rule.

In heart cases, however, we are dealing mainly with latent chronic syphilis, and there are without doubt a relatively large number of cases of cardiac lesions which give a negative Wassermann reaction. For instance, in one almost certain case of cardiac syphilis repeated Wassermann tests of the blood serum were negative, and the spinal fluid alone gave a positive reaction. Still the fact remains that a positive reaction in this country connotes syphilis in more than 90 per cent. of all cases.

I have profound faith in a positive Wassermann reaction for two reasons. In a large number of positive cases there was found corroborative evidence of lesions in the form of neuro-syphilis. More significant still, many of these cases responded to antisyphilitic treatment to such an extent as to leave no doubt about the character of the disease.

I think we are justified in concluding that a positive reaction, even with a single plus, goes a long way towards the establishment of a diagnosis of cardiac syphilis; still it does not indicate that a particular heart affection is syphilitic.

#### *Clinical Evidence of Cardiac Syphilis.*

Clinical evidence which is absolutely pathognomonic for syphilis of the heart does not exist. We diagnose heart disease by abnormal functions which it causes, but these manifest themselves in the same way, whether structural alteration has been caused by syphilis or not. Disease of the auriculo-ventricular bundle may give rise to block,

whether the disease is due to syphilis or to other factors. I maintain, however, that in many instances it is possible to diagnose syphilis of the heart with a high degree of probability from the clinical evidence alone, and in the majority of cases this evidence is such as to raise a strong suspicion of syphilis.

Broadly speaking, there are two features which are characteristic for cardiac syphilis. As is well known, this infection attacks the aorta and the coronary arteries, and disease of the latter gives rise to various affections of the myocardium. Syphilis affects the heart muscle with much greater frequency than does any other agent known to cause heart disease; there may be syphilitic aortitis, or aortic regurgitation, or other forms of infection, but usually the myocardium will also be damaged.

We may contrast this with the rheumatic valvular heart, where the myocardium is relatively seldom affected. Out of 88 electro-cardiograms of cases of cardiac syphilis, only 9 were normal; in the same number of cardiograms taken from rheumatic valvular heart cases 42 were normal. The cases of rheumatic origin were very much more advanced clinically than the syphilitic cases, so that the incidence of myocarditis in the rheumatic heart in relation to the syphilitic is relatively much less than these figures show.

This point is of practical importance in the diagnosis of syphilis. Take a case of aortic regurgitation in which, although it is not a very advanced case, there is evidence of myocarditis; this circumstance in itself favours the diagnosis of cardiac syphilis. In syphilis, moreover, the physical signs of a particular cardiac affection are not generally clean cut, the clinical picture is not usually true to type. In a case of rheumatic aortic regurgitation, for instance, the clinical signs are usually definite and correlated. There may be pronounced enlargement of the left ventricle, and the apex beat will be pointing outwards and downwards. There are usually such indications also as a pronounced water-hammer pulse, the different signs being correlated in a certain proportion. We may find such a picture occasionally in syphilitic aortic regurgitation, but in the majority of cases the clinical picture will be atypical. For instance, from an examination of the aortic area we may expect a large left ventricle and the typical appearance of the patient, but absence of one or the other indication is frequently observed. Again, in many instances, on examination of the heart we have difficulty in placing the abnormal signs in a definite category. The heart does not seem to be normal, and yet there are no distinct signs of valvular trouble; there is no enlargement in a given direction. We may be tempted to label it "tired" or "irritable" heart; it does not really fit in properly with either. In such circumstances it is advisable to investigate the case from the point of view of syphilis.

Passing from the general to the particular, aortitis is probably a most common event in syphilis; it must be remembered that syphilitic aortitis usually means syphilitic myocarditis. We may expect increased dullness over the aortic area, but this is not always easy to make out. In the early stage of aortitis we often depend for the diagnosis entirely on accentuation or alteration of the second aortic sound. I want particularly to emphasize the point that accentuation of the second aortic sound in the absence of high blood pressure, in cases where there is either a history of syphilis or a positive Wassermann reaction, is quite sufficient evidence for the diagnosis of syphilitic aortitis, and, incidentally, syphilitic myocarditis. Usually the left ventricle is slightly enlarged; often there is a systolic aortic murmur, a diastolic murmur appearing later. Characteristic of these murmurs is also the fact that they cannot be relied on to be always audible—they appear and disappear. It is easier to distinguish between aortic regurgitation due to syphilis and aortic regurgitation due to rheumatic fever, than between the former and aortic trouble secondary to such conditions as high blood pressure.

Syphilis does not seem to be a common factor in mitral disease. I have, however, had a number of typical cases of mitral stenosis with a positive Wassermann reaction and no history of rheumatic fever. Is mitral stenosis sometimes due to congenital syphilis? Syphilitic myocarditis, cardiac irregularities, extra-systole, auricular

fibrillation, heart-block, and branch bundle lesion are all common in syphilis, while the "large silent heart" is sometimes caused by it, and I have known instances of syphilitic pericarditis. Infective endocarditis sometimes gives a positive Wassermann reaction, and it is assumed in this case that such a reaction does not mean syphilis. It is, however, interesting that Byrom Bramwell,<sup>3</sup> in a book published before the Wassermann test came into vogue, gives syphilis as one of the causes of infective endocarditis; so acute an observer must have had good reason for his belief.

#### Symptoms.

Broadly speaking, symptoms of heart failure are the same, whether the underlying cause is syphilis or something else. It has been asserted that nocturnal dyspnoea is characteristic of cardiac syphilis. This has not been my experience, but as many of my cases are early cases of syphilis it is possible that if we take only advanced cases nocturnal dyspnoea may be more frequent. The one characteristic symptom of syphilis in my cases was cardiac pain, which was present in 70 per cent., but this pain has not usually the characteristic features of a classical angina pectoris. In my experience the great majority of typical cases of angina are not due to syphilis. The pain in the syphilitic variety is not so intense, does not appear so suddenly, and differs often in distribution from the pain met with in true angina; occasionally, however, the pain is similar.

The next important symptom is the gastric pain; pain is frequently referred to the stomach, simulating gastric ulcer, but the gastric symptoms are easily distinguishable from those which may be due to heart failure.

#### Electro-cardiographic Evidence.

The electro-cardiogram gives information about the condition of the myocardium and also the nature of different irregularities. The great majority of electro-cardiographic abnormalities, however, are not characteristic of syphilis, and only denote a damaged heart muscle. They are, however, of the utmost importance in the diagnosis of cardiac syphilis, because in many instances it is by means of the electro-cardiograph that we are able to demonstrate conclusively that there is something wrong with the heart. In my experience, however, there is one type of electro-cardiogram characteristic of syphilis—at least, I have so far not seen it in any other disease. It consists of certain wavelets all over the electric line.

Blood pressure reading yields nothing characteristic of syphilis of the heart; the majority of cases do not show abnormal blood pressure reading.

The result of treatment is often a valuable aid in diagnosis. A patient was admitted into hospital suffering from gastric symptoms, but obviously very ill. The electro-cardiograph revealed branch bundle lesion, a condition invariably fatal if not due to syphilis. In this case syphilis was subsequently admitted by the patient. Antispecific treatment of a few weeks' duration was sufficient to restore the patient to practically normal health, and the electro-cardiogram became normal. Another patient developed a heart affection which was diagnosed as tired heart; he got worse, was able to walk only a yard or two, and became almost blind. He denied syphilis. After admission to the Heart Hospital the Wassermann reaction was found to be double plus, and antisyphilitic treatment was so effective that this man is now able to follow his employment. In this case, no doubt, the diagnosis of syphilitic myocarditis was correct. All cases of cardiac syphilis do not show such good results under treatment, but in my experience the great majority improve definitely.

I have said sufficient to make it clear that from clinical evidence alone it is quite impossible in every case to diagnose syphilis of the heart with absolute certainty. The disease is very common. Those who concentrate on the subject will probably make fewer errors in diagnosis than others, but all sometimes overlook a case of cardiac syphilis. It is obviously a very serious matter to leave a case of syphilis without treatment. In my opinion we have no alternative but to adopt the Wassermann test as a routine procedure for all cases suffering from heart

disease. A positive reaction, particularly in a patient with some cardiac trouble, ought to be sufficient indication for a prolonged course of antisyphilitic treatment. We are making this test part of the routine examination at the Heart Hospital.

I am indebted to my house-physicians, Dr. Wilson and Dr. Waters, for their valuable help in connexion with the case-taking.

## SOME FUNDAMENTAL FACTORS IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

BY

SAMUEL H. STEWART, M.D. EDIN.,

SOUTHPORT;

LATE MEDICAL SUPERINTENDENT, BELFAST MUNICIPAL SANATORIUM.

IN the search for guiding principles in dealing with cases of pulmonary tuberculosis it is more instructive to approach the subject from the point of view of objective in treatment than to attempt a classification of methods.

The discovery of the tubercle bacillus by Koch led to the rational adoption of all those measures calculated to stimulate the normal resources of the body so that the patient might overcome the infecting micro-organism—indirect therapy. It was also to be expected that direct therapy, in the form of vaccines and serums, would emerge from the discovery. The aim of the direct and indirect therapies is, therefore, similar, for the objective in both instances is to overcome the tubercle bacillus on the lines of immunization, producing a serological immunity.

The issue is thus simplified, for, whether the patient is aided by such traditional methods as good food and fresh air in overcoming the infection, or whether vaccines and serums are administered, it is assumed that the toxin-antitoxin balance is involved, and that increase of the antitoxic content will lead to healing. The terms "toxin" and "antitoxin" are used here in the widest sense.

Now the existence of a toxin—probably entirely endotoxin—is established, but what evidence is available in favour of the existence of a specific antitoxin in the serological sense? That the human body must have some method of dealing with tubercle toxin is beyond question. Sanatorium principles and probably tuberculin therapy heighten the capacity to withstand tuberculous toxæmia, but the vital point remains: Does a highly positive resistance to toxæmia on the part of the patient necessarily overcome the tuberculous infection or lead to healing of the diseased focus? In other words, is the defence against the disease purely a local histological problem independent of systemic resistance beyond that required to maintain life?

In dealing with tuberculosis we have become so accustomed to accepting direct and indirect therapy as resting on an established basis that it may seem absurd even to open the question. Still, the answer to the previous query involves the validity of the present attitude to the treatment of this disease.

My survey covers some clinical and experimental aspects of tuberculin therapy, clinical observations, and pathological findings. I wish to emphasize that this survey is only an expression of my attitude to the question raised.

The presence of an antitoxin in the blood has not been proved by direct tests; besides, if such an antitoxin exists, its presence should be manifest in clinical experience.

#### TUBERCULIN.

To obtain evidence of this antitoxin as contrasted with detoxication tuberculin was studied. The first point to become prominent was that relatively enormous doses could be administered at the end of a gradually increasing course without any apparent improvement in the pulmonary lesion. In such a case the patient has obviously increased detoxicating power, the general condition may also be good, and yet such a favourable situation is not coincident with healing power.

Of course, it may be argued that the above citation is only an example of tolerance to injected toxin if focal reactions are ignored. At least one may accept increased tolerance to injected toxin and proceed to test the position as follows. It is recognized that a skin reaction to tuberculin is a miniature tuberculous lesion. Now lesions established cutaneously are capable of observation. As skin tests are more informative in children than in adults I selected altogether forty tuberculous children suitable for tuberculin therapy, and performed a quantitative skin test. A note was made of the sensitiveness and the time required by the papule to disappear. These children were treated with the same brand of tuberculin over a period of three months, the ultimate dosage varying with the capacity of the child. Within the period when I could still have injected the last dose of tuberculin—namely, on the eighth day—I repeated the quantitative test and made notes as before.

Comparison of the results revealed no relation in regard to either sensitiveness or duration of disappearance of the papule and the artificially produced systemic tolerance. One rather expected to find on the whole an increased sensitiveness.

Cutaneous reactions are too imperfectly understood to make any rash claims on the basis of these experiments; still, the trend of the results is again unfavourable to the standpoint that healing is necessarily dependent on systemic tolerance beyond that required to maintain life. I have simply recorded the results of these tests on a comparative basis in the same case without asserting a defined relationship between tissue and skin sensitiveness ordinarily.

These observations as to the effects of tuberculin are in accord with the attitude of the majority of tuberculosis workers to tuberculin therapy.

#### CLINICAL AND PATHOLOGICAL EVIDENCE.

There is an inevitable association in the information afforded by these two sources, consequently the facts are recorded under one heading.

Post-mortem records definitely indicate the power of the human body to cure tuberculous lesions in its own way; yet the exercise of this power fails to confer immunity to further disease. When disease occurs it is usually referred to as the result of broken-down immunity. Is this justifiable? If the factor determining activity of disease is failure of immunity, why should a patient suffering from prolonged pulmonary tuberculosis not produce disease in all parts of the body susceptible to the infection? "Lytic hypersensitiveness" is more a defence of a theory than an explanation of this fact. I think the infrequency of generalized tuberculosis in progressive phthisis is against reduced immunity as being the determining factor in resistance.

Again, it is a comparatively common experience to find latent disease becoming active as the result of a fall, a blow on the chest, the occurrence of an acute illness damaging the lung, or the resumption of a life where lung function is placed at a disadvantage. It is difficult to see how the humoral aspects of immunity are involved where the exciting cause is a fall or a blow. It seems to me that trauma is a more vital factor, and the same factor is at work where activity results from illness and bad environment.

These observations amount to a claim that trauma, or strain, is an important factor in the causation of tuberculosis, a factor, too, operating locally, and that general immunity as such is negligible. They do not, however, exclude a local cellular defence, a histogenous immunity, which in a sense is an enlightened way of referring to the "soil." It is not sufficient to explain away reactivation on the basis of a short-lived general immunity, because the longer a case has remained healed the less are the chances of renewed disease.

Now the same idea may be approached from a different clinical angle—namely, the progress of multiple lesions in a patient dying from tuberculosis. I had under observation for over two years a patient dying slowly from pulmonary tuberculosis, and during that period he effected apparent healing of an osseous lesion. In patients with

multiple lesions it is not uncommon to see some healing and others advancing, while the case as a whole is going downhill.

At this point it is interesting to survey the question of healing. It is recognized that healing in tuberculosis, as met clinically, is not by resolution, neither is it dependent on the extinction of the infection. The term "healing" in this disease is really more accurately regarded as a replacement of the primary physiologically active tissue by a practically inert substance which acts as a barrier to further damage by the bacillus. Such is the pathology of tuberculosis that any agent acting through the circulation must fall short of complete extirpation of the infection, and consequently tissue replacement will remain a vital factor.

On the above reasoning the classification of objectives in treatment as direct and indirect therapy does not seem to me well founded. With our present knowledge of immunity reactions, including the reaction of tuberculous and non-tuberculous subjects to infection and toxin, I cannot see that a case is made out for the humoral factors of immunity. The introduction of an intermediate factor, such as lysin, may explain the difference between immunity in tuberculosis and such a disease as diphtheria, but we have then only a hypothetical presentation of the subject, which does not fit in with clinical experience.

The specific reaction to infection and toxin when inoculated suggests a specific histogenous defence; it is a local phenomenon, and would not seem dependent on high general resistance to toxæmia on the part of the patient. In these days of much advertised serums it would be informing to have the basis of their efficiency.

Again, if the general resistance be not a vital factor in local defence, the basis for treatment by sanatorium and allied methods is still to be established as a stimulant to healing. That the sanatorium, being the embodiment of all those factors which make for health, is a sound treatment of the patient is beyond question. It is also obvious that the restoration of systemic resistance is desirable in the interests of living, but the elaborate building up of systemic resistance with the object of producing healing is very questionable. The sanatorium does, however, afford the patient an opportunity to effect healing which might be withheld in the less satisfactory environment of many homes.

For the sake of lucidity I might recapitulate that, first, treatment of the patient is not necessarily treatment of the disease, and secondly, the patient must be treated to allow time for the local cellular defence to effect restraint of the disease.

The treatment of the patient is that of a bacterial toxæmia; the treatment of the diseased lung is rather that of a damaged than an infected organ. I take this standpoint on the basis of the nature of the process, at present known; healing is mainly a replacement process, not even a replacement of the infection. The relative indifference to systemic tolerance and the after-history also seem to me to uphold such a standpoint. Even if a safe bactericide were found, such an attitude would still be indicated.

This presentation of the subject, in my opinion, demands rest of the damaged organ as a first step in treatment. Support for this demand is got from observation of cases—thus an attack of pleurisy often heralds an improvement in the disease; a serous effusion is also beneficial. The mechanical support arising from these conditions is apparently contributory. Again, a general review of tuberculosis reveals the great predominance of clinical disease in organs the function of which involves movement; mortality rates from tuberculous infection show the same association with mobile organs. Add to these observations the fact that where mechanical immobilization can be effected—as, for instance, in joints—the results of treatment are far superior to those obtaining in the case of the lungs. Surely, then, a *prima facie* case is made for rest in treatment.

Again, in the treatment of a pyrexial patient absolute rest is the only therapeutic measure available. The toxæmia is lessened because the lung is being less disturbed, and consequently the metabolic and excretory

functions are better controlled. It is agreed that toxæmia is much more easily overcome than the disease itself. Rest in bed brings about the recovery of the patient, but the disease remains a problem. To effect the local healing which I have previously emphasized I wish to suggest that local rest of the lung should be the aim at this stage, rather than graduated exercise. In short, the plan is local and general rest until toxæmia is controlled, followed, if possible, by continuous lung rest until repair has been effected.

#### SOME POINTS CONCERNING LOCAL REST.

Some hint as to the application of local rest is given by the observation of healing or healed cases. In such patients, apart from the attempt at muscular restraint, there is retraction of the chest wall; fuller investigation usually reveals displacement of the heart and mediastinum towards the diseased side. In other words, the diseased lung is permanently protected, in that its field of operation is finally restricted. This is usually referred to as a result of the pull of the fibrosing lung; I regard it rather as a compensatory process brought about by the healthier lung increasing its field of operation, and at the same time ensuring restraint of function on the part of the diseased organ.

It may reasonably be argued that there is no good outlook for bilateral cases. As a fact there is not much for the moderately advanced bilateral case; improvement, if any, is usually temporary. We all have seen rare cases of extensive tubercle clear up in an apparently miraculous manner. I have felt that most of such cases are examples of superficial lesions where the pleura contributes to the result by promoting fibrotic change, and an enhanced cellular defence may be in operation; but the miraculous case is not our problem.

To return to the question of retraction, which I have described as compensation, I wish to emphasize its vital importance. A tuberculous lung is an organ as permanently damaged as a heart with diseased valves. In the latter case every effort is made to establish compensation, whereas in the former I am not aware of any real recognition of such a process, which is probably more protective than functional.

To investigate the possibility of inducing compensation, and also the results accruing from it, I devised an appliance controlling the ribs on one side and leaving the opposite side comparatively free. In a suitable case it was found that rib restriction brought about some displacement of the mediastinum in a few weeks; this must be a compensatory process, as fibrous retraction could not be operative. It may be that the obvious is being laboured in this connexion, but its recognition in treatment is not obvious. As to results, I have no hesitation in asserting that, acting on the above basis, healing was effected in cases where other methods, including the sanatorium, had failed, and these patients have remained well over four years. These results are claimed for the principle; no claim of universal cures is intended.

In the production of rest certain factors have to be kept in mind. After considerable work on the question of rest in treatment I defined certain postulates, which are as follows:

1. The method must be capable of comparatively wide application.
2. The method must not restrict unduly those conditions which promote a healthy state of the body and mind.
3. It must promote compensation, and not impair to any considerable extent the normal function of the opposite lung.
4. In the event of healing being effected the patient's physique must be unimpaired.
5. It must recognize the mechanism of respiration.
6. The usual distribution of the disease must be noted and efforts made to promote rest at the zone of extension of the disease, and thus facilitate the formation of "barrier" tissue.

The postulates 1 to 4 require no further elaboration; a note on the last two, however, is indicated.

Enlargement of the thoracic cavity is brought about mainly by movement of the ribs below the second, and by diaphragmatic movement. Lung movements are subservient to these two factors. Thoracic enlargement in any direction causes general enlargement of the lung; thus Keith

has shown that movements of the diaphragm are reflected over at the lung apex. Again, tuberculous disease in the lung more frequently starts in the upper part and spreads downwards.

With these points in mind, it may be permissible for the sake of explanation to suggest that we have a lung fractured at the zone of extension of the disease, with an upper diseased and relatively immobile fragment, and a lower more actively movable fragment. With this conception it will be seen that rest can only be attained if restraint be applied to the more freely moving fragment.

#### CONCLUSION.

This paper is concerned with principles rather than methods. Further elaboration may be desirable in certain parts, but I think I have indicated sufficient grounds to justify a trial of more widespread surgical measures in treating pulmonary tuberculosis.

Condensation rather tends to give the impression of lack of balance in the statement of a case. Still, if I have made my objective clear, and given some indication of the lines along which it should be sought, my purpose in writing this article is attained.

### BRONCHO-PNEUMONIA IN CHILDREN TREATED BY INJECTIONS OF EMETINE HYDROCHLORIDE.

BY

C. ROBERTSON WILSON, M.B., Ch.B., D.P.H.Ed.,  
LATE SENIOR ASSISTANT MEDICAL OFFICER, BOOTH HALL INFIRMARY FOR  
CHILDREN, MANCHESTER.

THE alkaloid emetine, chiefly known for its specific action in amoebic dysentery, has in the past been vaunted as a remedy for other conditions, notably the arrest of hæmorrhage (especially hæmoptysis) and respiratory diseases. Within this latter group falls broncho-pneumonia, to which disease alone the ensuing observations refer. Burdick<sup>1</sup> says, "There is now accumulating evidence that the remedy has some beneficent action in this class of diseases aside from that due to its expectorant properties." He goes on to state that Raeburn, Flaudin, and others believe that this action is of a decongestant nature. Little seems to have been written concerning this method of treatment during the past ten years, so some further notes on the matter may perhaps prove of general interest.

#### The Booth Hall Observations.

The cases treated were not picked ones, but 50 consecutive cases of definite broncho-pneumonia, primary or secondary, admitted to the hospital, which takes patients from birth to 16 years old. As a control, 50 further cases treated by any other method were observed, these only being selected in so far that just the same number of secondary cases were taken as had occurred in the emetine series.

#### Dosage.

Bertrand<sup>2</sup> states that for pulmonary conditions he used a smaller dose than that normally given in dysenteric cases. The daily dosage used in this series was roughly in accordance with the following table:

Age up to 4 years ...	...	...	...	1/9 grain
4 to 10 years ...	...	...	...	1/6 "
10 to 15 years ...	...	...	...	1/3 "

These were used as commencing doses, but each case had to be judged by its reaction. In the majority of cases these amounts were found quite adequate to produce effects. The salt of emetine used was the hydrochloride, this being the most readily soluble, and the suitable quantity was administered daily by hypodermic injection.

The number of doses administered to any one case in the series varied from two to nine. In the main it was found that if at the end of six daily injections of the drug the case had not shown definite signs of settling, as regards temperature, pulse, respiration, and clinical picture, little further benefit was to be expected from its use. In a number of cases the doses were discontinued short of six.

*Conditions of Dosage.*

To ensure that the action of the emetine injections only was observed, no other expectorant or diaphoretic mixture was administered along with the treatment. The only additions permitted were local applications (such as antiplogistine), brandy, and injections of strychnine where desirable.

*Effects Observed.*

Even in those cases which did not finally settle after this treatment its effects were evident. These included a fall in the temperature after an injection and a corresponding fall in the pulse rate. The respirations seemed little affected directly, but gradually tended to follow the temperature and pulse. A striking loosening of the expectoration was soon evident, in some cases even after the first injection, and the type of the accompaniments heard on auscultation changed to the coarse bubbling type of rale.

At this point the cases seemed to divide themselves into two groups—one where expectoration became profuse and the chest cleared, the other where the chest appeared to clear up without the occurrence of the free expectoration. It is, of course, possible with children that sputum was swallowed in some of these cases, but this type of clearing seems to have been noted also by Rachburn<sup>1</sup> among his first group type of cases (non-tuberculous). Renou<sup>2</sup> found that the temperature fell, dyspnoea was reduced, and that the facility of expectoration was greatly increased. These effects he found more evident in broncho-pneumonias than in lobar pneumonias.

The depressant action of emetine never made itself really evident, and these cases did not require any more, in the way of stimulants, than the control series. The only case which showed a possible toxic sign (diarrhoea) was one in which the patient died with this as a terminal complication. Whether or not it was attributable to emetine is very doubtful.

Comparison of the figures obtained in the emetine series and those obtained in the control series is not encouraging. Both series consisted of 50 cases, and in each there were 42 primary and 8 secondary cases. The figures are as follows:

	Emetine Series.	Control Series.
Cured ... ..	27 = 54%	30 = 60%
Died ... ..	20 = 40%	20 = 40%
Recovered, but not settled after emetine ... ..	2 = 4%	Nil
Improving; removed by parents ... ..	1 = 2%	Nil

The average duration of febrile symptoms in cured cases was 4.5 days in the emetine series and 6.2 days in the control series.

*Conclusions.*

Both series give a death rate of 40 per cent., and the percentage of definite cures in each case does not differ greatly. Thus emetine hydrochloride on these results cannot be considered as a cure for broncho-pneumonia. The highness of the death rate in both instances may be condoned to some extent by the fact that the majority of the patients were drawn from the very poorest areas of Manchester, were initially possessed of a poor degree of natural resistance, and in many instances were brought to hospital too late to hope for really effective treatment.

The febrile period seems on an average to be reduced in the emetine series, and in both series the fall was by the usual form of lysis.

As previously mentioned, in no case were definite toxic symptoms present, nor was any undue depressant effect noted, nor did any objectionable local reaction occur following injection of the drug.

While not acclaiming the use of emetine as a specific remedy, it certainly appears to be of clinical value, and this may be summed up briefly as follows:

1. In children the effect gained by the daily injection saves in many instances a struggle with the child to get it to take medicines by the mouth, thus giving patient and attendant alike a more restful time. For this alone it should be a valuable method for the general practitioner,

where difficulty in this direction is only too often present owing to amateur nursing.

2. The febrile period of the disease appears quite definitely shortened when the average of cases is taken.

3. The stomach is left free from any irritation by expectorants and given a better chance with such nourishment as may be taken.

My thanks are due to Dr. J. D'Ewart, medical superintendent, for permission to make use of my observations.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## SARCOMA OF THE STOMACH.

Two cases of sarcoma of the stomach have been reported in the pages of the *British Medical Journal* during the past three months by Mr. James S. Hall and Dr. Alexander Smith. As this condition is so rare the following account of a recent case under my care in the Royal Isle of Wight County Hospital may be of interest.

The patient, a gardener, aged 32, had a fainting attack on January 9th, 1928. Previously, although he was anaemic and lackadaisical he had had no severe illness, nor suffered from dyspepsia or pain in the abdomen. On January 11th he had melaena, which lasted until January 20th. From that time onwards his health improved, although he was very weak and profoundly anaemic. The melaena was thought to be due to gastro-duodenal ulceration, for which he was treated. On February 5th, at 2 p.m., he complained of severe epigastric pain, which lasted continuously until he was seen by me at 9 p.m. At that time he looked very ill, and stated that the epigastric pain was still very severe. He had not vomited and his bowels had been well opened. The abdomen was moderately rigid and moved slightly on respiration, and the epigastrium was tender. The liver dullness was not obscured, but extended for two inches below the costal margin. Pulse 72, temperature normal. Nothing abnormal was found in the lungs. In view of this attack of pain supervening on an attack of melaena his condition was thought to be that of a ruptured gastric or duodenal ulcer, so he was removed to hospital for immediate operation.

*Operation.*—On opening the abdomen through a right paramedian incision a maroon-coloured tumour presented. This was delivered and was found to be pedunculated, having a pedicle one inch long and attached by a two-inch base to the lesser curvature of the stomach. The tumour was very much congested with large vessels coursing over its surface. It was firm, about the size of a foetal head, and had the appearance of sarcoma. The tumour was removed together with one inch of gastric wall beyond the attachment of the growth. The stomach was sutured by a double row of stitches, and the abdominal wound closed.

Except for a slight consolidation of the base of the left lung the patient had an uneventful convalescence, and he was discharged from hospital on March 3rd. On April 7th he reported himself to be much improved and able to take a fair amount of exercise and to do a little work. Before leaving the hospital a radiogram was taken of the patient's chest, but there were no signs of secondary deposits of sarcoma in the lungs.

*Pathological Report.*—The tumour was sent to Dr. L. Firman-Edwards, pathologist to the hospital, who reports: The tumour is a large brain-like mass about the size of a foetal head, with numerous small haemorrhages in it. It has the macroscopic appearance of a sarcoma. Microscopically the tumour is made up of spindle-shaped cells with large elongated nuclei, arranged in a whorl-like formation. Between the whorls the cells form a fine network like that of areolar tissue. There are no true blood vessels, but embryonic blood spaces occur throughout the section, and these have in many cases a lining of endothelial cells. The structure is typical of a spindle-celled sarcoma, although in some ways suggestive of an endothelioma.

This case is interesting in that, in spite of the size of the tumour, the patient had no symptoms until the fainting attack and the appearance of melaena, and one was led to suspect rupture of a gastric or duodenal ulcer owing to the sudden attack of acute epigastric pain on February 5th. This sudden onset of pain was undoubtedly due to torsion of the pedicle of the tumour. Its maroon appearance at the time of the operation, and the pathological report of numerous small haemorrhages in it, bear out this assumption.

A. H. HESLOR, M.B., B.S., F.R.C.S. Eng.,  
Surgeon to the Royal Isle of Wight County Hospital,  
Consulting Surgeon to King Edward VII Convalescent Home for Officers, Osborne.

## A CASE OF POLYDACTYLISM IN THE FOOT.

ALTHOUGH cases of polydactylism may not be extremely uncommon, it must be rare indeed that an instance, such as that recorded below, is met with in which the patient has as many as three additional digits on one foot. There is, too, more often than not an hereditary tendency to the deformity. This was absent in the present case. Miles Atkinson, in the *British Journal of Surgery* (vol. 9, 1921-22, p. 298), records a case of hereditary polydactylism, in which it was possible to trace the occurrence of the deformity back through four generations: of 48 persons traced, 26, or more than half, exhibited a condition of polydactylism. In no instance, however, was there more than one extra digit on any one limb; although Atkinson

mentions that cases have been reported in which there were as many as eight digits on one hand, and a case with nine toes occurred in America.

The present patient was a lady, aged 82, who was found to have eight separate and fully formed toes on the left foot. On inquiry I could not trace any other member of the family with a similar deformity; indeed, the relatives did not know that the patient had anything wrong with her foot at all. Unfortunately no radiogram of the foot could be obtained.

I am indebted to Dr. Campbell of the Public Health Department for the excellent photograph with which this note is illustrated.

A. ERNEST SAWDAY, M.B., B.S.Lond.,  
F.R.C.S.E.,  
Honorary Surgeon, Derbyshire Hospital  
for Sick Children.

## Reports of Societies.

EARLY DIAGNOSIS OF CANCER OF RECTUM  
AND COLON.

At a meeting of the Subsection of Proctology of the Royal Society of Medicine on May 9th the subject of the early diagnosis of cancer of the rectum and colon was debated. The chair was taken by Sir CHARLES GORDON-WATSON.

Sir WILLIAM DE COURCY WHEELER, dealing with the surgical aspect, said that he was doubtful whether he had ever seen an early case of cancer of the rectum or the colon, and from the literature he discovered that most surgeons had had the same lamentable experience with regard to late recognition. In the Breslau clinic 70 per cent. of cases of cancer of the rectum were inoperable on arrival, and he thought the figure for St. Mark's, London, was similar. In connexion with the lack of early recognition, he drew attention to the relative frequency of cancer of the distal portion of the colon, because it was just in this situation that early diagnosis ought to be made. From the diagnostic point of view, cancers in the distal region were really external cancers, comparable with cancer of the breast. If early diagnosis could be made there would be a rich reward, for even under present conditions 50 per cent. of excisions of cancer of the rectum, and 60 per cent. in the case of the colon, were followed

by five years' cure. Moreover, under modern conditions, the operative mortality was becoming negligible. With so many missed diagnoses it would be profitable to review the diagnostic armoury. All the authorities he had consulted commented on the lack of thorough examination in suspicious cases. Each patient ought to be examined thoroughly, but he thought it only fair that those who specialized in this branch of surgery should make allowance for the busy general practitioner, who was often misled by high abdominal symptoms predominating in the first instance. He himself had seen several cases, and there were many recorded in literature, which had been examined for dyspepsia by x rays on many occasions, when the cause was within easy reach of the finger in the rectum. Numbers of cases of cancer of the rectum were mistaken for haemorrhoids owing to perfunctory examinations, notwithstanding the fact that students were taught to beware of so inexcusable a mistake. It might help in arriving at an early diagnosis if students examined the pelvis bimanually per rectum in the same thorough and systematic way as the vaginal examination was performed by gynaecologists. Just as tumours in the rectum and rectal sigmoid were easily felt, so tumours higher up could be easily seen, and the simplicity of the sigmoidoscopic examination was insufficiently realized. No examination of this kind was complete without employing x rays after a bismuth meal and bismuth enema, but here he wanted to sound a note of warning to the general practitioner, that radiologists were not infallible, nor were their dicta akin to the gospel. Often a practitioner sent a suspicious case to a radiologist straight away; nothing definite was seen, and the case was left for perhaps a year until an inoperable growth had made its appearance. He thought it a grave mistake to take a radiological report as proof positive of either absence or presence of a rectal or colonic growth, though he gladly admitted that the bricks of the diagnostic building were cemented together by the radiological findings. In the routine examination of the faeces occult blood was not found unless there was some definite alteration of the gastro-intestinal tract. After speculating on the cause of the anaemia in cancer of the colon, which might be due to the loss of small amounts of blood, he said that the anaemia was never a contraindication to operation, though exploration should be the last resort. If there were occult blood and suspicious symptoms, and if the x-ray findings were suggestive, the case was one for exploration, supposing no tumour was palpable. Unfortunately there always remained a group of patients who would not seek medical advice. They corrected their constipation by purgatives, their diarrhoea by astringents, and their lassitude and weakness by change of air and holidays; they were doctored by themselves, their friends, and the daily press. Some good might come in this respect from cancer campaigns, and the public must be taught to avoid those paths of neglect which led inevitably to the grave.

Dr. CUTHBERT DUKES described the way in which the pathologist could be of most service in the diagnosis of cancer at an early stage. He would leave on one side those still unsettled problems of pathology that centred round the origin of malignancy, and limit himself to answering the practical question, "What can a pathologist do to help the surgeon make up his mind whether or not his patient has cancer of the bowel?" and said that the answer was disappointingly brief; it was limited to the fragment removed for diagnosis. He knew no reliable way of recognizing those changes in the blood which must accompany cancer from its first beginning. Some time ago he had hopes of agglutination tests with a peculiar strain of *B. coli*, but the procedure proved useless for diagnosis, because only in the later stages of cancer was it positive, and even then the results were often equivocal. Similarly, the alterations in the urine which eventually accompanied rectal cancer arrived too late to be of practical value in diagnosis. The chemical and microscopical examination of the faeces had been explored almost in vain. The occult blood test might be useful in certain cases, but many other possible sources of blood in the stool had to be borne in mind. The prospect of finding a fragment of cancer epithelium in the

daily dejecta was about as hopeless as the search for a needle in a haystack. There was, however, one aspect of recent work at St. Mark's Hospital which might be useful to surgeons. The so-called innocent adenoma of the bowel was a frequent precursor of cancer, and Dr. Dukes had had the opportunity of demonstrating to the Subsection preparations illustrating the onset of malignancy in adenomatous tumours, pointing out how often an early bowel cancer was accompanied by a cluster of sessile adenomata and patches of epithelial hyperplasia scattered over the mucous membrane for several inches above and below the growth. The existence of these proliferations was a warning against the misconception of regarding the malignant disease as strictly limited to the area of the bowel which bore the cancer. If on sigmoidoscopic examination no obviously malignant tumour were discovered, this observation should point to the need for a very close medical supervision in the immediate future, with re-examinations with the sigmoidoscope. With regard to the microscopic examination of fragments of suspected tumour, already defined as the most useful function of the pathologist in early diagnosis, it was worth while to consider which particular region of the tumour was most likely to permit a decisive opinion. The pathologist made up his mind chiefly from the general disposition of the cells and their relation to neighbouring tissues. Too much reliance should not be placed on the morphology of individual cells, for in a rapidly growing adenoma in which the interrelationship of the epithelium was strictly preserved, and in which there was no encroachment into subjacent tissues, cells might be found which exhibited all the generally accepted marks of malignancy. The individual cancer cell, separated from its fellows and neighbours, possessed no histological feature that might not be paralleled in a cell separated from a non-malignant tumour. With isolated cells the highest magnification could not distinguish the malignant from the benign. Much more could be learnt from the general arrangement of the epithelium, but this also must not be taken as an invariable guide, because the disorderly disposition of the cells in cancer might be closely mimicked by the proliferation of a benign tumour. The only unequivocal sign of cancer of the bowel was the intrusion of atypical epithelium into regions where such epithelium was not normally found. The particular features which the pathologist wished to study were most conspicuous in the tissue at the edge of the tumour. A fragment removed from this region would show the normal epithelium side by side with the neoplastic, and would allow of comparisons being made between the natural histological appearance and the disorderly disposition of the new growth. Moreover, the margin of the cancer was its growing point, and therefore a fragment from the edge was the best means of recognizing the nuclear peculiarities of malignant cells. The manner of removal of the fragment was important. It should be handled carefully, and not squeezed or cut with the knife or scissors. If the fragment could be removed by dissection that was the method of choice, but almost equally satisfactory samples could be obtained by means of a punch. Finally, it was well to remember that a negative report, stating that there was no evidence of malignancy discoverable, did not necessarily imply that the whole tumour was benign. The report referred only to the particular portion sent for examination.

Dr. GRAHAM HODGSON, who spoke from the radiological point of view, said that it was generally acknowledged that an efficient x-ray examination could be of great assistance to the surgeon by confirming clinical suspicions and by localizing the growth and defining its extent. The most important radiological sign of carcinoma of the colon was a filling defect, and he showed on the screen many examples of the radiographical appearance of this. Early growth in the part of the colon where the calibre was wide, as in the caecum, was very apt to escape observation if screened or radiographed in the antero-posterior plane. In these situations oblique views were essential. He also described the dual exposure technique.

Dr. ARTHUR F. HURST said that the advanced period in the case at which the surgeon or physician saw the patient was lamentable. In his last twenty-four private cases the

average duration of symptoms before the patient came to him was ten and a half months. A careful history of symptoms was the most important thing in diagnosis. The patient usually had some definite abdominal symptoms, which came on fairly suddenly after a period of health; generally there was discomfort and some change in the regularity of the bowel action, almost as often a tendency to looseness and irregularity as to constipation. On further investigation it was striking how infrequently was there any abnormality in the stools. Out of the twenty-four cases just mentioned the stools in only five showed, on naked-eye examination, any abnormality, but on a more elaborate examination occult blood was found without a single exception. He thought that of all the signs and symptoms the presence of occult blood was the most constant. He had never yet seen a case of growth in the stomach or colon without occult blood being present. Occult blood might, however, also be found in one or two other conditions, including rare cases of tuberculosis of the colon, and, curiously enough, localized adhesions. With regard to x-ray examination, all were agreed as to its great value, but it was very important to realize that there were cases of fairly advanced growth of the colon in which a barium enema showed no abnormality. Both the delay and the shape of the filling defect helped to distinguish the growth from other conditions which might simulate it. He emphasized the value of the sigmoidoscope, and added that until this was recognized as an instrument which the general practitioner ought to use cases would be missed. There were certain cases, however, in which the sigmoidoscope did not help, and diagnosis depended on indirect methods, such as x rays and occult blood. In the earliest cases of all x rays were negative, no tumour was palpable, and all one had was the history and the occult blood.

Mr. J. P. LOCKHART-MUMMERY said that if growths in the colon were detected during the early stage the results of operation were admirable, and the recurrence rate low. He doubted whether 25 per cent. of cases of carcinoma of the colon ever reached the surgeon in an operable state. Methods of diagnosing carcinoma of the colon had improved enormously during the last twenty years. In his early practice it was extremely rare to come across a case unless there was acute obstruction, but now in at least half the cases of carcinoma of the colon that he saw there was no obstruction, or such obstruction as existed was relieved without operation. The improvement in diagnosis was partly due to the use of the sigmoidoscope, partly to the testing of occult blood, and very largely to the x-ray picture and its careful interpretation. The x rays were most useful as confirmatory evidence, though they should never be taken as negating a positive diagnosis. The general practitioner, however, was coming to realize the importance of early and thorough investigation, and the education of the public would follow in due course.

Mr. W. B. GAMMEL said that among the out-patients at St. Mark's he had discovered during the last few years an appreciable number of early carcinomas which the patients themselves had not suspected, having come for some minor condition such as piles.

Mr. L. E. C. NORBURY emphasized the need of routine examination of the patients. He had had two cases of unsuspected carcinoma of the lower sigmoid in youngish patients who came up with a history of recent piles. It was tempting to assume that that minor cause was the whole trouble, but the sigmoidoscope showed an early growth. Any youngish patient who gave a recent history of piles should be very carefully examined with a view to the detection of carcinoma. The general practitioner could help more, but the trouble was that the national insurance system practitioners had such huge lists as to make it quite impossible for them to perform any routine examination.

Mr. E. T. C. MILLIGAN thought it very important that the patient should not undergo any preparation before a sigmoidoscopic examination, since, if the bowel was washed out before using the instrument, the whole appearance was often changed. Frequently the sigmoidoscope enabled a diagnosis to be made, even in the absence of a shigram.

In a tumour high up palpation should always be performed, since it might indicate whether induration was present.

Sir WILLIAM WHEELER, replying briefly on the discussion, touched on the difficulty of learning the subsequent course of events after patients had been operated upon. One practitioner to whom he wrote specially about a patient who had survived for at least four years after operation replied that the man had suddenly disappeared. The speaker did not think a patient should be sent to the radiologist without particulars, since a negative report was more likely, and the patient might drift on in false security. There was value in the suggestion that preparation should not precede an examination with the sigmoidoscope.

### BOTHRIOCEPHALUS INFECTION.

At the annual general meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine on May 3rd the president, Professor R. T. LEIPER, described a cryptic infection with *Dibothriocephalus latus*.

Professor Leiper said that it had frequently been supposed that bothriocephalus infection in man caused a serious type of pernicious anaemia, but experimental proof of this was still lacking. In 1922 a number of experimental infections in man with this parasite had been undertaken in his department at the London School of Tropical Medicine. Two of these were maintained for over three months, and the parasites were then expelled with molo fern. No appreciable anaemia was produced, but there was an eosinophilia which increased to about 15 to 16 per cent. after three weeks, and thereafter diminished to about 2 per cent. for the remaining time. In one of these cases treatment was apparently successful as, although no heads were recovered, no ova were found in the stool after several weeks. In February, 1928, the patient contracted bacillary dysentery in Egypt, and an examination of his stool in connexion with this infection disclosed the fact that the tapeworm was still present. Professor Leiper thought that there was little doubt that this was a continuation of the original infection. An examination of the blood showed that the eosinophilia was still under 2 per cent., while the total count was 7,000,000 red and 6,150 white cells. The only clinical symptoms were occasional tenderness in the epigastrium beneath the gall-bladder, and at other times in the region of the umbilicus and the appendix. No migrating segments of the tapeworm had been seen in the stool since treatment, although careful search had been made for them. The fact that no anaemia had developed during the five years of infection suggested that there was still some unknown contributory factor involved in this so-called bothriocephalus anaemia. Professor Leiper also demonstrated sections of the intestine of an experimentally infected animal to show that the fluke *Heterophyes heterophyes* was actually pathogenic and caused an erosion of the mucosa. Finally, he drew attention to the fact that bilharzia disease, which had been reported from Cyprus many years ago by Dr. G. A. Williamson, had recently been found by himself still in the same endemic focus. Four out of seventeen boys examined had ova in their urine. A prolonged search for snails disclosed *Bullinus* locally, although not elsewhere on the island. Cyprus, geologically, was connected with Asia Minor—not with Egypt—and the recovery of *Bullinus* from various other islands in the Mediterranean suggested that it was once widespread before the submergence of the basin. The parasite might have come to Cyprus either from Egypt or from Syria.

#### Climate and Epidemic Disease.

Sir LEONARD ROGERS then gave a lantern demonstration entitled "Climate and the incidence of small-pox, plague, and cholera, and the forecasting of epidemics." He said that small-pox epidemics had gradually decreased as vaccination had increased, and epidemics were now irregular in India. The incidence was high in certain States, such as the Punjab and the United Provinces, but very low in Bengal; he showed that it varied directly with the absolute humidity, and not with the temperature. A low absolute

humidity was always followed by an epidemic. In England, owing to lack of vaccination, the disease had increased over sixtyfold in the last six years, and here also the lowest absolute humidity (which was in December) was followed by an increase in the number of cases in January. The reverse was also true, and the lowest number of cases was in the month following the lowest absolute humidity. Here, of course, relative humidity and absolute humidity were almost equal. Plague varied very much in India with population, temperature, and the species of rat flea present, but Sir Leonard Rogers demonstrated that the epidemics depended on the saturation deficiency, computed from the absolute humidity and the temperature; when this was low plague was low in the following year. Cholera was believed a hundred years ago to have spread all over India from a focus in Bengal, but it did not do so now. If the absolute humidity was low the disease died out in the cold weather, and widespread cholera was impossible. The various outbreaks followed the rise in absolute humidity. The endemic areas in India were Assam, Bihar, South-East India, and Bombay, where it had not been absent during the past thirty years. A knowledge of these facts would enable the local authorities to forecast epidemics and take the necessary steps to stop fairs and pilgrimages, or to make arrangements for combating the infection in time.

### THE KAHN TEST FOR SYPHILIS.

At a meeting of the Scottish Branch of the Medical Society for the Study of Venereal Diseases on May 2nd, in the Hall of the Royal Faculty of Physicians and Surgeons of Glasgow, with Dr. W. G. CLARK in the chair, Dr. R. L. KAHN gave a lecture on the clinical aspects of the Kahn reaction.

Dr. Kahn first reviewed the history of serum diagnosis of syphilis, touching upon the discovery of the *Spirochaeta pallida* by Schaudinn and Hofmann, the extension of knowledge about complement fixation by Bordet and Gengou, and the development of the Wassermann test by Wassermann, Neisser, and Bruck. He then discussed the early attempts to develop a precipitation test for syphilis, beginning with that of Michaelis in 1907, and reviewed the work of Sachs and Georgi, Meinicke, and Dreyer and Ward. Dr. Kahn said that his own early studies were in connexion with the phenomenon of precipitation. He showed that the requirements for optimum precipitation results when syphilitic serum was mixed with an antigen-saline suspension were as follows: (1) optimum concentration of antigenic lipoids in the antigen, excessive or deficient concentration preventing precipitation; (2) proper physical state of antigen suspension; (3) correct quantitative relation between serum and antigen suspension: the number of antigen units must not exceed the number of serum units; (4) shaking—as a probable means in hastening collision between the interacting particles; (5) dilution of the mixture of serum and antigen suspension should be a minimum. These observations formed the basis of the Kahn test. The outstanding features of the test were its relative simplicity in performance, the rapidity in obtaining results—the test requiring no incubation and being completed after shaking the reagents for three minutes—its relative economy, its availability in all parts of the world, and its application to research in extending knowledge of the serum diagnosis of syphilis. With regard to the relation between the Kahn and Wassermann tests, Dr. Kahn claimed that the interaction between serum and antigen was the same in both. The result of this interaction was directly visible in the Kahn test by the formation of a precipitate, while in the Wassermann test, the result being invisible, a special indicator (the haemolytic system) was employed to render the reaction visible. The Kahn test was described as being highly specific for syphilis and not affected by pathological conditions other than syphilis, but it should not supplant careful clinical study of each case. Dr. Kahn also discussed such extensions as the quantitative serum test, the qualitative and quantitative spinal fluid investigations, and the more sensitive "presumptive" procedure.

## Rebichus.

### FRACTURES OF THE NECK OF THE FEMUR.

PROFESSOR PIERRE DELBET is well known as an advocate of early surgical intervention in the treatment of fractures and some other injuries. Two of his disciples, Drs. Jacques LEVEUF and CHARLES GIRODE, surgeons to the hospitals of Paris, have put on record their experiences in the study of operations for fracture of the femoral neck, with special reference to the remote results of such proceedings.<sup>1</sup> Their statistics include 83 cases treated with metal screws and 57 treated with autogenous bone grafts or heterogeneous bone pegs, including 7 in which the methods of autogenous graft and metal screw were combined. The mortality of the metal screw cases amounted to 13.25 per cent., while that in the bone graft cases was only 3.5 per cent. The authors explain that this great contrast is due to the severity of the cases subjected to the metal screw method being much greater, and that also these cases were all recent, while the others were not so. In a late series of metal screw cases (1920-24) there have been no deaths. As to the old bugbear of hypostatic pneumonia and the dangers of keeping elderly people in bed, it has become the custom in Professor Delbet's wards to keep patients in bed for sixty days, so as to make sure of good union before allowing walking.

In the second part of the book an elaborate apparatus and its application are described, by the use of which the position of the fragments is ascertained under the x rays. This appliance is maintained in place during transit from the x-ray room and upon the operating table. It carries a guide through which drills and pegs or screws are passed, and the authors claim that with its use they can be sure of inserting pegs and screws in the correct position in the neck and head of the femur. The operation thus performed is not subcutaneous, for the great trochanter has to be exposed by incision through skin, fascia, and muscles, but the joint is not opened except in so far as is necessitated by the passage of a peg into the head. From January, 1924, to May, 1926, 23 cases were operated upon in this manner with 2 deaths—one, aged 50, from acute suppurative arthritis, and one, aged 67, from cardio-pulmonary affection forty-eight hours after operation. Fifteen results are classed as "good," and 6 as "bad," excluding the 2 fatal cases.

This report, if we may so term it, is a valuable one and full of information, and it can be recommended to those who are interested in the treatment of this troublesome fracture. The apparatus described by the authors appears to us to be complicated and clumsy, but the fact remains that in their hands its use has given good results. Evidently much practice, accuracy, skill, and team work are required for the successful use of this machine. That it does not exclude the risk of sepsis, against which it was chiefly designed, is shown by the facts recorded by MM. Leveuf and Girode. We think that in those cases for which nailing is thought more suitable than Whitman's abduction method most British surgeons will continue to prefer the open method such as was described by Mr. Hey Groves in his Bradshaw Lecture (*British Journal of Surgery*, vol. 14, p. 485), by which the actual state of things can be exposed to the eye of the operator, and all chance of the interposition of soft parts between the fragments is done away with.

### RADIOGRAPHY OF THE URINARY TRACT.

So many advances have been made since the publication of Dr. W. F. BRAASCH's work on *Urography*<sup>2</sup> ten years ago that his second edition, prepared in collaboration with Dr. B. H. HAGER, is to all intents and purposes a new book. By the comprehensive title of "urography" is meant

all methods of investigating the urinary tract by x rays after distending the lumen with opaque fluid. At one time this method of study was confined to the pelvis and calyces of the kidney, but it has now been used throughout the whole of the urinary system. Dr. Braasch's position at the Mayo Clinic has afforded him unique opportunities for the employment of urography, and it may be said without hesitation that the collection of plates published in his new work is the finest that we have seen.

In the chapter dealing with the normal renal pelvis as many as ninety-nine excellent pyelograms have been produced, showing every variety of kidney that may be considered to lie within the range of normality. This large collection allows the reader to appreciate the various forms the normal pelvis may take. Since the chief danger in the interpretation of a pyelogram lies in the mistaking of a variation of the normal kidney for an abnormality, the reproduction of this excellent collection is invaluable. Following the section on the normal kidney are chapters dealing with abnormalities of position, dilatation from obstruction, dilatation of the pelvis and ureter resulting from inflammation, renal and ureteral calculi, renal tumours, and congenital abnormalities. All of them are illustrated with excellent plates, and in the text sound advice is given on the subject of diagnosis. Chapter xi is devoted to cystography. The author has found, as have many other urologists, that the use of solutions of the halogens is often followed by intense pain, and he has therefore employed, for the purpose of distending the bladder, a 5 per cent. emulsion of silver iodide. This not only serves as an excellent opaque medium, but has the advantage of exerting a soothing antiseptic action on an inflamed bladder. He has found cystography of use in the diagnosis of diverticula, new growths, and prostatic enlargement. For the making of urethrograms he employs the same solution of silver iodide, placing the patient in the dorso-lateral position and tilting the pelvis to an angle of 45 degrees with the horizontal. The urethra is distended by means of a syringe, and the opaque solution is injected during the entire time of exposure. This is necessary, since otherwise the posterior urethra will not be shown on the plate, owing to the rapid escape of fluid into the bladder.

In conclusion it may be said that this is the most complete work on the subject that has yet been published in the English language. The illustrations have been chosen from what must be one of the finest collections of pyelograms at the command of any single urologist, and discrimination and a nice sense of proportion have been shown in deciding on those which should be reproduced. The text, which deals chiefly with the interpretation of the plates, is written in clear and simple language, so that the author's reasons for arriving at his diagnosis are easily appreciated. Certain more recent allied methods of diagnosis, such as pycloscopy, have not been included within the scope of the work, but otherwise it may be regarded as complete. It is unfortunate that the cost of reproducing so many plates has forced the publishers to make the price of the work so high as it is.

### METHODS OF CLINICAL DIAGNOSIS.

In choosing the volumes which are to form his own intimate library for immediate and ready reference, it is of the utmost importance for the student and the recently qualified man to include at least one of those handy little books which deal with the bedrock elements of professional knowledge, without which the most comprehensive display of textbooks is but as the sounding brass and the tinkling cymbal. In extending a hearty welcome to the latest of these, *The Methods of Clinical Diagnosis*,<sup>3</sup> by Drs. A. G. GIBSON and W. T. COLLIER, it is safe to predict for it a speedy popularity. The authors wisely remark that more errors are due to the omission of some part of the examination of a patient than to misinterpretation of the signs discovered, and throughout the book emphasis is laid on the systematic observation of every

<sup>1</sup> *Le Traitement des Fractures du Col du Fémur*. Par Jacques Leveuf et Ch. Girode. Paris: Masson et Cie. (Roy. 8vo, pp. 148; 164 figures, 30 fr. sans majoration.)

<sup>2</sup> *Urography*. By William F. Braasch, B.S., M.D., F.A.C.S. In collaboration with Benjamin H. Hager, B.S., M.D. Second edition, revised and enlarged. Philadelphia and London: W. B. Saunders Company. (Roy. 8vo, pp. 480; 759 figures. 60s. net.)

<sup>3</sup> *The Methods of Clinical Diagnosis*. By Alexander George Gibson, M.D., F.R.C.P., and William Tregonwell Collier, M.D., M.R.C.P. London: E. Arnold and Co. (Cr. 8vo, pp. viii + 353; 136 figures. 12s. 6d. net.)

detail so that even the slightest sign of abnormality may not be missed.

The book follows the lines usually adopted in works of this kind. Commencing with an account of the general methods of examination commonly employed, a chapter is devoted to the examination of the regions of the body from scalp to sole. The systems are then discussed seriatim, special chapters being devoted to the examination of children and to clinical pathology. The book is packed with useful information presented in a lucid and interesting manner. Throughout attention is focused on clinical observation, instrumental and laboratory investigations being very properly shown to be supplementary to and never to be substituted for a thorough examination of the patient himself. At the same time all the chemical methods in general everyday use, such as the fractional test-meal, tests of renal efficiency, urine analysis, and so forth, are briefly but clearly described.

It is surprising what a wealth of information the authors have compressed within 398 pages, and that they should have done so in such a readable manner is proof that they have accomplished what they set out to perform. The make-up of this book is a great advance upon that of some, at least, of its popular prototypes. The printing is clear and the diagrams are adequate. A work such as this will be constantly referred to not only by the student, but by the man in busy practice. Drs. Gibson and Collier are to be congratulated upon producing a volume worthy of the school which Sir William Osler did so much to invigorate and revitalize.

#### THE MEDICAL ANNUAL, 1928.

The *Medical Annual*<sup>4</sup> is an old and tried friend and its reappearance is always welcome; the forty-sixth issue, with its array of able contributors and its wealth of practical information, fulfils our expectations. Research is no longer confined to the laboratory; all clinical workers have become imbued with its spirit. Although 1927 was not marked by the discovery of any outstanding specific remedy, there has been much steady progress. In medicine the liver treatment of pernicious anaemia has occupied a great deal of attention during the past year, and two papers appear on this subject in the volume under review; one of them deals with the principles on which the treatment is based and their significance in relation to the prognosis and pathogenesis of this disease. An interesting summary of the malarial and other microbial methods in pyrexial therapy is given. Alcoholism is dealt with by two writers—in relation to tests for drunkenness and to the treatment of chronic inebriety—and there are articles on the value of antimony in kala-azar and of chaulmoogra oil in leprosy. The specific serum for employment in acute poliomyelitis, prepared by the Pasteur Institute of Paris, and the treatment of epilepsy are discussed; while a group of papers deals with epidemic encephalitis. There is a careful review of present knowledge about vitamins. Among newer drugs, cardiazol, novasurol, and ouabain are considered in relation to their action on circulatory failure. Students of preventive medicine will find much of interest in the papers on the reduction of infantile mortality, on the etiology of rheumatic fever, on isolation with quarantine in pneumonia, and on epidemics in boarding schools. Two modern methods of treating gonorrhoea are described: by intra-urethral and subcutaneous injections of toxin-free gonococcal preparations, and by irrigations with mercurochrome and glucose. The suggestions for the treatment of cases of gonorrhoea and syphilis on the lines followed at St. Thomas's Hospital deserve attention.

Recent progress in surgery is reflected in papers dealing with toxic symptoms in appendicitis and their treatment with anti-gas-gangrene serum, the importance of the CO<sub>2</sub> content of the blood in abdominal surgery, prolapse of the rectum, cerebral abscess, oesophageal spasm, and intussusceptions in children. A case is recorded in which the abdominal aorta was successfully ligatured. A paper on the treatment of sprains and synovitis should prove of

value to the general practitioner; and the articles on the isolation of an organism in cases of trachoma, on the relation of foreign proteins to conjunctival spring catarrh, and on the effect of the cinema on the eyes will be of interest to the ophthalmologist. Many obstetrical and gynaecological papers appear, among which may be mentioned those on gonital prolapse, sterility, and the care of the pregnant woman. Various anaesthetics and anaesthetic measures are described, and the series of papers on radiotherapy contains much helpful information. Scattered throughout the book will be found many practical notes on diagnostic methods, such as liver function tests and cholecystography, and a section is given to the pathology of "late" rickets.

The usefulness of the *Annual* is much increased by well-reproduced diagrams and plates, and by the inclusion of items of general information, such as lists of new drugs and medical and surgical appliances; books of the year and medical and scientific periodicals; a directory of sanatoriums, spas, and other institutions; and an official and medical trades directory. Of the work as a whole we may say that the editors, Dr. Carey Coombs and Mr. Rendle Short, have once more performed a difficult task with skill and judgement.

#### FOUR TEXTBOOKS OF BACTERIOLOGY.

Dr. WHITBY's book *Medical Bacteriology*<sup>5</sup> is a conveniently sized handbook on medical laboratory methods. A short description is given in the first part of the book of all the pathogenic bacteria and protozoa and the commoner helminths, and in the second part, devoted to applied bacteriology, the author discusses the use of bacterial preparations, the collection and examination of specimens, laboratory aids in the diagnosis and treatment of individual diseases, and the bacteriology of water, milk, and food. For the student this volume has the merit of being neither too detailed nor too condensed, and for the regular laboratory worker its practical outlook should ensure it a prominent place of reference on the bookshelf.

We have before us an old copy of the fifth edition of ZINSSER's *Text Book of Bacteriology*, which appeared in 1922, and also the sixth edition of 1927, and we notice many additions in the present edition,<sup>6</sup> notably in the new section on the pathogenic protozoa and in the sections dealing with immunology. Substantial alterations have been made in the chapters on pneumonia and streptococcus diseases; a separate section dealing with scarlet fever has been inserted; the chapters on the filterable virus have been completely rewritten and rearranged. These are only a few of the changes. We notice that in every chapter of this long and carefully documented book the author has persevered in his original plan of providing a fairly full account of the present state of our knowledge of the bacteriology of the infectious diseases, with critical reference to many modern developments of theory and technique.

Professor FORD's *Text-Book of Bacteriology*<sup>7</sup> is an example of an attempt to give a complete and accurate description of the microbes commonly encountered in routine bacteriological work in medicine, comparative pathology, hygiene, and public health. But the impartial cataloguing of this host of microscopic creatures is almost a superhuman task, and the author has been forced to give prominence to the human pathogenic bacteria and the problems they create, and to give only a brief description to all other bacteria. Although the book begins by approaching bacteriology as an independent science, the reader is conscious of a change of direction as he proceeds through the sections of general and systematic bacteriology to those which deal with infection and immunity. But

<sup>5</sup> *Medical Bacteriology: Descriptive and Applied, including Elementary Helminthology*. By L. E. H. Whitby, M.D. Camb., M.R.C.P. Lond., D.P.H. London: J. and A. Churchill. 1928. (5 + 81, pp. vii + 320; 74 figures. 10s. 6d.)

<sup>6</sup> *A Text Book of Bacteriology*. By Hans Zinsser, M.D. With a section on pathogenic protozoa by E. E. Tyzzer, M.D. Sixth edition, rewritten, revised, and reset. New York and London: D. Appleton and Co. 1927. (Med. 8vo, pp. xx + 1053; 181 figures. 30s. net.)

<sup>7</sup> *Text-Book of Bacteriology*. By William W. Ford. Philadelphia and London: W. B. Saunders Company. 1927. (Roy. 8vo, pp. 1069; 186 figures, 9 plates. 37s. 6d. net.)

<sup>4</sup> *The Medical Annual*. Forty-sixth year. Bristol: J. Wright and Sons, Ltd. London: Simpkin, Marshall, Ltd. 1928. (Demy 8vo, pp. xcix + 630; 120 figures, 55 plates. 20s. net.)

the additional information that the book contains which is not found in ordinary medical textbooks of bacteriology is extremely useful for reference purposes, as is also the unusually detailed treatment of the spirochaetes in Part V.

In its original form STITT'S *Practical Bacteriology, Blood Work, and Animal Parasitology* was intended to serve as a textbook in clinical pathology for students of the American Naval Medical School, but with the enlargements of subsequent editions the former plan of a pocket manual has been abandoned, and the book has now grown to more than 800 pages. We have directed attention to earlier editions as they have appeared, and need only say that the revision now accomplished has not entailed any fundamental alterations, except perhaps the adoption of the terminology of the Society of American Bacteriologists in the "keys" at the beginning of each chapter. The previous names have, however, been retained in the descriptive matter and in the clinical notes of the bacteria important in human pathology.

#### THE PIRQUET SYSTEM OF NUTRITION.

In 1923 Dr. E. NOBEL published an account of the Pirquet system of nutrition, which had been devised in Vienna during the war and post-war period. In preparing a second edition of this little book on the nutrition of healthy and sick children,<sup>9</sup> intended for the use of practitioners and students, he has had the assistance of Professor PIRQUET and Dr. R. WAGNER. It is arranged in two sections. The first, of less than twenty pages, explains the theoretical aspects of the subject; the second deals at much greater length with the practical applications of the method, first to healthy and then to sick children. It may be recalled that the basis of the system is the use of the "nem," defined as the nutritive value of one gram of standard human milk, and the nutritional requirements are worked out from the square of the "sitting height." It is shown that there is a relation between the weight and the sitting height: in the healthy adult the sitting height in centimetres equals the cube root of ten times the weight in grams. These facts are mentioned because the obvious criticism of the system as here set out is that it is unnecessary and adds complications to what is already often a feat of mental arithmetic—namely, infant feeding. These basic criticisms of the system apart, however, this little book gives an excellent and well-illustrated summary of the nutrition of the healthy and the sick child, and it is a good example of how to concentrate much mental pabulum in a very small bulk.

#### NOTES ON BOOKS.

The familiar little practical textbook of *Experimental Physiology*<sup>10</sup>, by Sir E. SHARPEY-SCHAFER must have tutored a long line of medical students during its academic life of fifteen years. It now renews its youth in a fourth edition. The occasion for the present edition appears to be merely that its predecessor has run out of print, rather than any signs of ageing of its substance, for the text remains virtually unchanged. There appear a total of eight new pages, for which the reviewer can account by the addition of one or two new experiments—for example, on chronaxy and on the entoptic appearances of the lens and vitreous humour—and an occasional clarification and elaboration of technical descriptions.

The fourth edition of the now well-known *Recent Advances in Medicine*<sup>11</sup> by Dr. G. E. BEAUMONT and Professor E. C. DODDS, has been brought up to date by many minor changes in the various chapters. A new section has been added on spinal cord compression which gives an account of combined cisternal and lumbar puncture, with an illustrated description of lipiodol in the diagnosis of spinal cord compression. In the chapter on disorders of the endocrine system a section has been included

on the parathyroids, and the clinical applications of the use of the new potent extract of these glands are carefully considered. A fuller and clearer description of the action of quinine now appears in the chapter on the heart, and there is also an account of "cat-unit tablets" of digitalis leaves in the treatment of heart failure. The extended care which has been taken with the bibliography at the end of each chapter and the wide scope of the authors quoted make this a particularly valuable book, not only for post-graduate students, but as a reference work for those studying for higher examinations. In short, this new edition maintains the high standard of "Beaumont and Dodds."

In *The Divine Origin of the Craft of the Herbalist*,<sup>12</sup> written at the request of the Society of Herbalists, Sir A. E. WALLIS BUDGE, formerly keeper of Egyptian and Assyrian antiquities of the British Museum, describes briefly the attributes and works of the earliest gods of medicine in Mesopotamia and Egypt, and shows that the Sumerian, Egyptian, Babylonian, and Assyrian herbals formed the basis of the Greek herbals, which were translated into Syriac and Arabic, and thus became known in Western Asia, spreading to Turkestan and China. The great nations of antiquity believed that the gods were the first herbalists, and taught the denizens of this world the art of healing by plants and herbs, which were regarded as composed of, or containing parts of, the bodies of the gods. Water was to the Egyptians "the Father of the Gods," and "the Water of Life," and Osiris was a grain god and introduced wheat and the vine into their country; vegetable oils were early recognized as valuable in protecting the skin from the heat, and, indeed, were regarded as effluxes from the body of Ra, the Sun God. The herbals of various nations are described, with illustrations from manuscripts in the British Museum. Sir Wallis Budge, while recalling that the herbalist craft fell into sad disrepute in the nineteenth century, and illustrating this by his early recollections of a herbalist's shop in 1865, suggests that the craft may now be regaining its rightful position in Great Britain among the systems of medicine which have been evolved by generations of men in their efforts to heal their bodies.

Dr. KENNETH ROGERS, who has explored deeply the records at the Guildhall and various parish registers, has written an interesting pamphlet on *The Boar's Head Tavern in Eastcheap*.<sup>13</sup> Incidentally, he has recovered the names of the vintners, and helped to locate the exact site of the tavern. Of this supposed resort of Falstaff and Prince Hal in Shakespeare's *Henry IV* nothing now remains except the original sign in the Guildhall Museum and the Falstaff cup and the tobacco box which were used at vestry meetings of St. Michael's parish when held in the tavern. St. Michael's, one of Wren's churches, and the tavern buildings were both demolished in 1830 to make room for the approach to the new London Bridge. Dr. Rogers's booklet is illustrated with pictures of St. Michael's Church, the Boar's Head, sundry tokens, and the Falstaff cup.

#### PREPARATIONS AND APPLIANCES.

##### A DUAL CONTROL UNIT FOR RADIOGRAPHY.

A FACILITY having some resemblance to that which was afforded to the photographer in the advent of the reflex camera is now forthcoming in radiology by a device brought out by Newton and Wright, Limited, of Hornsey Road, London. It has often happened that the radiologist, while watching the image on the fluorescent screen, has desired to make a plate record of some condition only visible for a short period. To do this, however, has necessitated the suspension of the screen examination and the making of certain adjustments, by which time, probably, the phenomenon has disappeared, and the plate reveals nothing unusual. By this new arrangement, which is known as the "Holway" dual control unit, the controls on the main switchboard are adjusted for the production of the necessary radiographic current through the tube, but for the time being these are left in reserve. The patient is examined with the screen, and, thanks to the dual control, the ordinary screening current, which, of course, is much less than that required for rapid radiography, is employed. When any appearance of which it is desired to make a permanent record presents itself a half-plate cassette, which had been fixed in a kind of protective tunnel, is slipped instantaneously into position, and by means of a foot control the current required for radiography is at once passed through the tube. After this the screen examination may be resumed, again by the manipulation of a foot control. It is a happy contrivance, capable of being used in conjunction with almost any type of x-ray plant, and judging by the number of times we have heard x-ray workers lament the lack of something of the kind—to record, for example, a filling defect in the duodenum—it should achieve considerable popularity.

<sup>9</sup> *Practical Bacteriology, Blood Work, and Animal Parasitology*. By E. R. Stitt, Ph.D., M.D., Sc.D., LL.D. Eighth edition. London: H. K. Lewis and Co., Ltd. 1927. (Post 8vo, pp. xv + 837; 685 figures. 2s. net.)

# CONFERENCE ON RHEUMATIC DISEASES.

BATH, May 10th and 11th, 1928.

THE Conference on Rheumatic Diseases, which took place at Bath on Thursday and Friday, May 10th and 11th, proved the success which its hard-working promoters deserved. It was attended by a very large proportion of those whose names have been identified with recent investigations into the subject, also by many delegates from local authorities, and it attracted some distinguished visitors from France, Italy, Belgium, Holland, and Denmark. The medical profession in Bath supported it in large numbers, and the fact that the annual meeting of the Balneological Section of the Royal Society of Medicine was held in that city on the day following the Conference helped to swell the attendance. At no period of the meeting, not even at the wane of the sessions, were there fewer than 250 present.

The president was Sir George Newman, Chief Medical Officer of the Ministry of Health, but each of the three sessions—on social aspects, on causation, and on treatment—had its separate chairman—namely, Lord Dawson of Penn, and the two Regius Professors, Sir Humphry Rolleston, Bt., and Sir Farquhar Buzzard respectively. During the day and a half of the meeting thirty communications were presented. Their authors were in most cases compelled to make a severe condensation—a task evidently neither easy nor congenial—but only so could time be allotted for general discussion. Even as it was, the great mass of written material, as well as the shortness of time available, rather hindered that free interchange of views and experience which the word "conference" implies. The Organization Committee had taken the greatest pains for months past in planning every detail, with the result that all the papers were printed in advance and were available for distribution, and will be published subsequently in a volume.

The city of Bath was hospitality itself. The only shadow on the occasion was the illness of the Mayor (Alderman Cedric Chivers), who had taken a most generous share in facilitating the Conference. In his absence the Deputy Mayor (Mr. C. H. Hacker) expressed the local welcome, to which Sir George Newman, as president, replied. He mentioned that the Minister of Health first of all had been invited to preside, but found himself unable to do so owing to numerous political engagements; when in due course the invitation was transferred to the Chief Medical Officer of the Ministry Mr. Chamberlain expressed the earnest wish that he (Sir George) should attend, and state with what interest and expectation the Minister viewed the occasion.

## Presidential Introduction: The Problem Stated.

In a brief presidential address Sir GEORGE NEWMAN said that the Conference had assembled to consider the nature of the campaign to be organized for the conquest or control of rheumatism. The urgency of this matter had been made manifest by the advance of knowledge of the heterogeneous group of morbid joint conditions and by the data furnished for the first time by the school medical service and the health insurance system. It was now known that acute rheumatism of children was sowing seeds of a growing harvest of disease of the heart and nervous system, and that the chronic forms of rheumatism were seriously crippling many hundreds of thousands of people. The disease was a drag on industry, a heavy handicap on the worker, a source of oppressive financial loss to the State, and a potent cause of excessive mortality and ill health. The main difficulties were three: (1) neither the respective relation of the varied forms of rheumatism to each other, nor their distribution over the world generally or in this country, could as yet be exactly defined; (2) the *causa causans* of this morbid group was not known with

certainly; (3) the varied medical experience was not yet in working accord as to the best means of treatment. Happily advances were being made in all three directions, but they awaited integration. "In treatment some swear by heat and light, and others by water, some by massage and manipulation, and others by rest, and some, rightly enough, swear not at all, but proceed from case to case with tentative empiricism." The hypothesis which at present held the field was that acute rheumatism was the reaction of the human body to the presence of the *Streptococcus viridans*, possibly a constant habitant of the body, in which event attention must be concentrated on the conditions, circumstances, or predispositions, external or internal, which induced it to assume an activity resulting in rheumatic fever. Speaking broadly, the attempt must be made steadily to improve the personal and environmental hygiene of childhood, a closer and more vigilant supervision must be exercised over susceptible children by the infant welfare and school medical services, and the methods of diagnosis and treatment of those found suffering from the beginnings of this disease must be organized. In chronic rheumatism of the adult there must be further intensive and comprehensive investigation, not only in the laboratory, but at the bedside, and even in the factory and workshop. As in acute rheumatism, so here research was needed into the social and causative aspects, and experience of therapeutic measures must be pooled. Not only must there be medical co-operation, but also the co-operation of contributory public agencies, such as social, health, and hospital services. He closed by giving some general counsel to those suffering from any degree or form of chronic rheumatism, first, to seek medical advice and submit to the removal of possible sources of infection in their own bodies; secondly, personal hygiene and strict moderation and selection in food and drink, exercise, and so forth; thirdly, vigilance in avoiding predisposing conditions, such as dampness and chill, unsuitable clothing, excessive use, misuse, or disuse of the stricken joints, or a clogged alimentary system.

## SOCIAL ASPECTS.

### The Cost to the Nation.

Sir WALTER S. KINNEAR, Controller of Health and Pension Insurance, Ministry of Health, opened the Social Aspects session by an estimate of the cost to the country of industrial rheumatism. He applied to the most recent sickness experience of insured persons—that for 1927—the conclusions of the Ministry's committee on the incidence of rheumatic diseases, which reported in 1924. The committee found that approximately one-sixth of the total period for which sickness and disablement benefit was paid to men (one-seventh in the case of women) was due to rheumatic diseases. In 1927 such total benefit in Great Britain amounted to £20,000,000, representing 34,000,000 weeks' incapacity. Making certain adjustments, he thought it probable that the incapacity due to rheumatism amounted to 5,500,000 weeks, with an approximate disbursement under the insurance scheme of £5,000,000. To this must be added about £12,000,000 as the amount of wages lost to insured persons through rheumatism, and even this total of £17,000,000 did not include anything for the cost of medical treatment of sufferers not totally incapable of work, the cost of nursing in bad cases, or the necessary institutional treatment, nor did it cover fully persons over 70, or make any allowance for dependants of insured persons.

### Organization of Medical Treatment.

Dr. H. B. BRACKENBURY, Chairman of Council, British Medical Association, spoke on the organization of medical treatment of industrial rheumatism. He described such treatment as including the elimination of infected foci, the

administration of drugs, and the use of various physical agencies or methods. The problem of organization was to provide treatment for those unable to provide it for themselves, without any waste on unsuitable cases, or unnecessary travelling or superfluous equipment, but with the greatest available knowledge, experience, and skill placed at the service of the patients, and with every possible facility for education and research. After tracing the attempts made in Germany and Holland to secure this organization, he said that this effort—he was speaking principally of the German effort—did not afford the guidance which might have been expected. Most of it appeared to be a little haphazard; there did not seem to be that careful selection of suitable cases, considered prescription of appropriate treatment, or adequate supervision of treatment given which was so desirable. Any organized scheme must secure the goodwill of the medical profession and of the approved societies. Unfortunately, under present conditions in this country, not every insured person was entitled to specialist and ancillary help of the required type. This was unfortunate, and the medical profession was almost universally in agreement with the report of the Royal Commission that specialist advice and treatment of all kinds should become part of statutory benefit as soon as possible, and be available for all insured persons and administered by some responsible public body. Two practical schemes, compatible with the provisions of the amending Insurance Bill before Parliament had now been submitted to the profession and the public. One was the out-patient clinic to be established in London under the auspices of the British Red Cross Society, and the other the scheme for spa treatment of insured persons under the auspices of the British Spa Federation. The latter had received, certain conditions being accepted, the approval of the Council of the British Medical Association. It was to be hoped that both these schemes would become operative, and, indeed, that they would be united, but they must conform to certain requirements if they were to receive the hearty support of the medical profession—namely, that no patient should be treated except on the recommendation of a registered medical practitioner, that any patient who could easily obtain the requisite treatment for himself should be refused, that where conditions made such a course feasible the possibility of a patient obtaining medical advice at the private consulting room of a specialist instead of an institution should be provided, and that there should be suitable opportunity for practitioners to observe and obtain experience of the methods employed and their results. One consideration which Dr. Brackenbury stressed was the need for co-operation of the recommending practitioner and the specialist. Organized medical treatment for industrial rheumatism, both at spas and at suitably equipped clinics in the larger towns, should prove a sound national and economic investment, but if disappointment was to be avoided something more than zeal and optimism were required; the problem to be solved was primarily one of medical science, and not of philanthropy. The main value of an organized scheme or institution would consist in the improved facilities and opportunities it would afford for that clinical and pathological observation and research which was so necessary for further success in combating an obstinate national scourge.

#### *Continental Experience.*

The last speaker had made a special mention of the pioneer out-patient clinic for physical treatment opened in Amsterdam in 1905, and its founder and director, Dr. J. VAN BREEMEN, followed with some remarks on the problem in Holland. After a statistical review, his general conclusions were that the number of cases of rheumatic fever, not only in children, but in adults, was relatively small in Holland, also that the number of cases of rheumatoid arthritis was smaller than in England. He mentioned that the Dutch Society for Combating Rheumatism, founded last year, was collecting statistical data on the incidence of rheumatic diseases, and that with regard to nomenclature, which was the first problem to be tackled, the Society had adopted the nomenclature of the British Ministry of Health, as set forth in its report in 1924. As secretary of the International Committee on Rheumatism also Dr. Van

Breemen had remarked with satisfaction that several other countries had adopted this same nomenclature.

Dr. HANS JANSEN of Copenhagen gave some account of the various groups of cases treated annually in the physiotherapeutic department of the Bispebjerg Hospital. He differentiated between primary chronic progressive polyarthritis and secondary chronic rheumatic polyarthritis, as did his and other German authors, though he knew it might be very difficult to divide them. In his opinion progressive polyarthritis—real rheumatoid arthritis—was a disease *sui generis*, probably of endocrine nature, while secondary chronic rheumatic polyarthritis was simply the result of rheumatic fever, often of repeated attacks, and certainly of infective nature.

#### *Environment and Incidence.*

Dr. REGINALD MILLER, who was honorary secretary of the British Medical Association Subcommittee on Rheumatic Heart Disease in Children, spoke on the influence of environment on rheumatic infection in childhood. Juvenile rheumatism, he said, was massed amongst the children of the poor and practically absent from the children of the well-to-do. This class incidence was so clear that until the explanation of it was known the large-scale production of the disease could not be understood. It was not due to case-to-case infection. The general trend of medical opinion was in favour of regarding it as an environmental disease. So close was the association between juvenile rheumatism and tonsillar disease that it seemed as though the environmental factors at work must to some extent centre round the production of diseased infected tonsils. One of the reasons for the immunity to rheumatism amongst well-to-do children was the present-day practice of early and complete removal of the tonsils. It was probably not correct to regard juvenile rheumatism as a poverty disease, for there was evidence that its frequency did not necessarily increase as the lower depths of poverty were reached. Poverty was a predisposing cause of immense importance, but some other factor, a common concomitant of poverty, must also be at work. Dr. Miller believed that the environmental factor of chief importance, combined with poverty, was damp dwellings. These had a real and particular connexion with the development of juvenile rheumatism. Residence in damp dwellings governed to some extent the distribution of the disease within the rheumatic stratum of society, and determined in many cases why one family suffered and another of the same grade of poverty escaped.

The closing paper of the session was read by Dr. J. ALISON GLOVER of the Ministry of Health, who spoke on the general incidence of rheumatic diseases. He accepted an estimate of 5 per cent. as the proportion of patients in general practice whose ills might be classified under the heading "rheumatic." He even ventured on an estimate of the number and species of rheumatic patients seen by an insurance practitioner with a list of 2,000 (1,000 males and 1,000 females), all of them persons over 15 years of age. Such a practitioner during the year would see, for all diseases and accidents, 930 of the persons on his list, and of these some 55 (35 males and 22 females) would be suffering from rheumatic disease, of whom 9, if the law of averages held good, might be expected to belong to the acute rheumatic group, 30 to the fibrositis group, and the remainder to the chronic arthritis group. The incidence of acute rheumatism (rheumatic fever) was one of the bright spots in the present position of rheumatic diseases. It was undoubtedly declining; in the Royal Navy, for example, it had fallen markedly. In exhibiting a table illustrating the occupational incidence Dr. Glover drew attention to the extraordinary incidence of all forms of rheumatic disease, but especially osteo-arthritis, among workers in metals. With regard to chronic conditions, whose importance was one of the many startling silhouettes of State medicine revealed by the financial searchlight of national insurance, he quoted some figures from hospitals which showed, what was generally agreed, that the large general hospitals worked under such severe pressure from more acute cases that they could not admit more than the smallest fringe of cases of chronic arthritis. Further institutional provision was necessary for dealing with chronic arthritis, in which disease there was a stage when the patient's admission to

an institution, with the range of diagnostic method and treatment there available, would be very advantageous.

Dr. R. G. GORDON of Bath said that no disease could be attributed to one etiological factor, and perhaps this platitude was more applicable to the chronic rheumatic diseases than to most others. No one could doubt that in all forms of fibrositis, infective arthritis, and more indirectly osteo-arthritis, faulty elimination played an essential part, and it might be that too little attention had been paid to intrinsic poisoning, resulting from failure by the patient to get rid of his waste products of metabolism. In almost every case the skin was at fault in some way or other, and he specially invited attention to certain factors making for inefficiency in the proper secretion of sweat. These were, first, a humid, cold atmosphere; secondly, fatigue (in which skin action was notoriously upset, excessive sweats occurring alternately with periods of complete inaction), and thirdly, emotional strain, for it was a commonplace that emotions affected the skin—for example, the sweat of terror and the dry skin of anxiety, an effect probably brought about almost entirely through endocrine, and especially thyroid, activity. It would do no harm when dealing with these rheumatic conditions to bear in mind the effects of climate, fatigue, and emotional strain, especially worry and depression.

LORD DAWSON OF PENN, who presided over this session, deprecated the allusion to rheumatism as a "poverty disease," because this carried with it the implication that if the poverty were removed the disease also would disappear. But the incidence of the disease was not in proportion to the poverty. It was found, for example, in the families of railwaymen and postmen, who, though not affluent, could not be classified as poor. It was the domestic environment which needed altering. He ventured to say that the improvement in the housing of the working class, better ventilated homes, more sufficient and sensible clothing, a better ordered dietary, would all play a larger part than the mere question of poverty. Recreation, too, he regarded as extremely important—not merely time for recreation, but its right employment. It was not so much more recreation that was needed as more knowledge of how to use it. In this connexion he thought that while the securing of the eight-hour day had been invaluable to the worker, there was some disadvantage in making it too rigid. He thought it would be well if, while maintaining the average, the worker could on certain days work for nine or perhaps even ten hours, so that at the end of the week he would have an accumulated leisure which would be available for recreation really worth while. This redistribution of hours of work and recreation might be recommended to the serious attention of those controlling industry. Lord Dawson added that some of the troubles of rheumatism which were noted with advancing years were to a large extent an expression of strain—the over-use or unbalanced use of certain body structures. Where there was strain there was increased liability to infection. Damp and cold were the precipitating causes, but in the background the determining factor was fatigue, often long continued.

#### THE CAUSATION OF RHEUMATISM.

The second session was presided over by Sir HUMPHRY ROLLESTON, who, in some brief opening remarks, said that the term "rheumatic diseases" was convenient if umbrella-like, as it included these acute and chronic infections, rheumatic fever and the rheumatoid groups; and it might be well to raise again the question of the relation of these groups to each other, and to consider whether there were any connecting links or common etiological factors. At one end of the scale there was acute rheumatic fever, which might mainly or exclusively attack the heart, and when it had not done so was remarkably amenable to salicylates; at the other end, there was osteo-arthritis, largely if not entirely a degenerative lesion, which did not induce cardiac lesions and did not respond to salicylate treatment. Between these two extremes there was a chain of gradual transitions. The characteristic lesion of rheumatic fever was the formation of nodules, large in the subcutaneous tissues, submiliary in the heart. Subcutaneous nodules had often been found in rheumatoid

arthritis and osteo-arthritis, but he had not found any evidence that the submiliary nodules occurred in the heart in chronic rheumatism. Fibrositis, the non-arthritic form of chronic rheumatism, was also accompanied by nodulo formation. These thickenings were not so characteristic histologically as the rheumatic nodule, but Dr. Hadfield would presently exhibit to the Conference microscopical sections of panniculitis demonstrating endarteritis, and so showing evidence of a blood-borne agent, and at any rate some resemblance to the rheumatic nodule. Panniculitis, like fibrositis and fibromyositis, might be due to various causes, and possibly it was stretching a point to correlate its fibrotic thickenings with submiliary nodules. As to infective factors, Sir Humphry Rolleston said that the much-debated streptococcal nature of acute rheumatism, in spite of criticism, had steadily gained ground. It might be argued that the various members of the family of rheumatic diseases were streptococcal in origin, and that their clinical and structural differences depended on variations in the "seed" and inborn or acquired differences in the "soil"—namely, the constitutional, metabolic, and endocrine factors. On the whole, the speaker concluded that it might be reasonable to suggest that varying degrees of diminished constitutional resistance of the fibrous tissues or of sensitization to infection on the one hand, and on the other the action of different kinds of streptococci, might explain the different clinical manifestations seen among the diseases grouped for convenience under the heading "rheumatic."

#### Predisposing Factors in Childhood.

Professor WILFRED VINING of Leeds University brought forward the thesis that the large majority of rheumatic children had a history of health defect for months or years before they developed their first frank rheumatic attack, that their health defect, if carried on into the rheumatic period, did much to colour the complete picture of the rheumatic child, and that it bore a very intimate relationship to the clinical rheumatic affection which followed. It was a relationship which might be much more than, say, the relationship between being "run down" and the development of an attack of influenza. In his opinion the pre-rheumatic child was at least a potential rheumatic child, perhaps a child sown already with the seeds of rheumatism: To his mind this relationship seemed clear from the frequency with which the preceding health defect occurred, the peculiar and significant repetition of the same group of symptoms, and the fact that so many of these symptoms, such as nervous instability and limb pains, had in the past been recognized as pointing to the rheumatic child. That a toxæmia was in existence, and that it was bacterial in origin, few would deny. As to where this toxæmia arose, the throat suggested itself, but this was not a complete explanation; the relationship of abnormal states of the intestinal tract to the pre-rheumatic debility had to be considered. Professor Vining believed that the child's digestive system was a factor in the etiology of rheumatism which had failed to receive adequate recognition. Rheumatism in childhood was primarily a disease based upon a nutritional disturbance brought about by a prolonged dietetic deficiency, either in vitamin B or in protein in conjunction with a relative excess of carbohydrate, or possibly both these factors. While the brunt of the defect fell upon the alimentary tract, yet the results were widespread, and produced loss of tone in all the systems. Secondly, rheumatism was a streptococcal infection, the organism passing through the weakened lines of defence, and so producing the toxæmic element of the debility.

Dr. DINGWALL FORDYCE, honorary physician, Royal Liverpool Children's Hospital, mentioned three predisposing factors in rheumatic infection in childhood—namely, instability of the nervous system, digestive disorder, and weakness of lymphoid defence. He held that while the first two were usually closely associated, the third might result in rheumatic infection without either of the other conditions being marked. When all three were marked there was serious danger of heart infection and chorea; when nervous instability and digestive disorder alone were marked the threat was chorea, and when lymphoid weakness alone

was marked the danger was of heart infection, while chorea was not much to be feared. The predisposing factors as he saw them were simple and homely, and on that very account difficult to control. The moral seemed to be that there was no royal road to the prevention of rheumatism. If, however, there were more beds at command in country hospitals, and adequate provision of suitable residential schools, the scourge of rheumatic heart disease would be very largely swept away.

#### *The Bacterial Factor.*

The bacterial origin of rheumatism was discussed by Dr. CAREY COOMBS, physician to the Bristol General Hospital. He held that the causal factor was infection rather than intoxication, and that the infection was blood-borne. To the question as to the portal by which the streptococcal organisms entered the blood channels only an incomplete answer could be returned. That the tonsils were responsible in many instances was so probable that it might perhaps be treated as proved. The clinical evidence in support of the view that the streptococci might enter through the intestinal wall appeared to him vague, but it was on the face of it unlikely that there should be only one spot in the whole alimentary tract through which these streptococci could penetrate to the vital fluids, and therefore he could not feel satisfied if the tonsil only was blamed. The view might be accepted that the tonsil was certainly, and the intestinal mucosa possibly, responsible for admitting this virus into the systemic circulation. But there remained some unknown quantity in the equation whereby the balance between defence and attack was upset in favour of the latter. For the moment he did not feel able to claim more than that the streptococci were probably derived from the alimentary tract in which they were always present, that it was only by a conjunction of extraneous influences that they were enabled to inflict injury to the tissues, and that the fact that the injuries inflicted conformed closely to a certain pattern observable even in histological details was due rather to constancy on the part of these extraneous influences than to the specificity of the organisms themselves.

#### *The Cardiac Problem.*

Rheumatic fever visualized as essentially a cardiac problem was the subject of a paper by Professor FERNAND BEZANÇON and Dr. MATHIEU-PIERRE WEIL of Paris, which was read by the latter. The authors considered that the general point of view with regard to rheumatism should be completely changed, that the disease should not be considered as consisting of a series of acute lesions, first articular and later cardiac, but rather as a true chronic disease, similar to tuberculosis. The articular lesions appeared the most important only because of their painful nature, which prevented them from passing unnoticed. The endo-pericarditis was really much more important, and this after a period of development readily became obscured again until a definite cardiopathy was established which led to cardiac irregularity. The reservoir of the rheumatic virus was the heart, the endocardium, the pericardium, and particularly the myocardium. The acute attacks were distinguished either by a recrudescence of the cardiac lesion or by fresh articular symptoms. The authors held that this method of interpreting the fundamental part played by the heart was the only way of explaining the development of the disease, which frequently, after a stage during which articular and cardiac signs were present simultaneously, progressed with cardiac signs only, and became more and more severe.

#### *Fibrositis and Panniculitis.*

The causation of fibrositis and panniculitis was discussed by Professor RALPH STOCKMAN of Glasgow. In fibrositis, he said, the irritant was most commonly a bacterial toxin produced either at the site of the lesions by small colonies of microbes which had established themselves there, or it was carried possibly from a more distant site by the blood stream. Cold and wet had from time immemorial been cited as causes of chronic rheumatism, and it was possible that they might be capable of setting up a fibrositis, but he was inclined to regard them more as exacerbating

factors when the lesions were already present. With regard to the etiology of panniculitis, this was quite a different condition from obesity or myxoedema. Many women at the menopause tended to lay on fat, and if they happened to be subjects of subcutaneous fibrositis they then began to suffer, or suffer more severely, from its effects. The explanation was probably an increased growth of the connective tissue to support the mass of fat, and increased tension due to weight. Professor Stockman showed some lantern slides of ancient carvings which indicated that panniculitis was a frequent and perhaps a fashionable condition among females in earlier civilizations, as it was with certain primitive tribes at the present day.

#### *Pathological Investigations.*

Dr. GEOFFREY HADFIELD, demonstrator of pathology at Bristol University, described a recent investigation made with the object of discovering whether there was a specific tissue reaction in the chronic rheumatic disorders or any group of them. More work needed to be done, but enough had been brought out to justify certain statements, such as that in some types of infective arthritis skin nodules occurred, having a constant histological structure, which appeared to resemble the primary lesion of acute rheumatism in the heart wall, skin, and synovia closely enough to make it likely that both were due to a micro-organism of the same group. A similar tissue reaction was occasionally found in the lesions of the more chronic types of endocarditis, which appeared to be due to local infection by faecal or oral streptococci in patients whose general immunity to these organisms was high. The work suggested—but did no more than suggest—that in chronic infective arthritis infection was by a saprophytic streptococcus to which the patient had a high degree of general immunity, but a low degree of local immunity in the synovia of his joints.

A paper on the comparative pathology of the subject was read by Professor TOM HARE of the Royal Veterinary College, London. It described a study of equine arthritis. Not only horses, but dogs, and possibly dairy cattle, are infected with rheumatic disease, and Professor Hare said that there was evidence for the belief that it originated in them in early maturity. Heredity, sex, food, and environment did not appear to have any etiological significance.

#### *The Endocrine Factor.*

The question of the endocrine factor called forth two or three contributions. Dr. W. LANGDON BROWN thought that attention should be confined to the thyroid and the ovaries. Any influence that the other endocrine glands might have was, to say the least, problematical. It was a striking fact that, as the recent report of the Ministry of Health showed, the incidence of mortality from acute and cardiac rheumatism, and also the incidence of rheumatoid arthritis and osteo-arthritis, were markedly higher in regions where goitre was endemic. While not going quite so far as Llewellyn, who held that the hereditary transmission of rheumatism consisted in the transmission of a tendency to thyroid inadequacy or instability, Dr. Langdon Brown agreed that such inadequacy or instability was a factor of importance. He believed that tonsillar sepsis played a large part both in rheumatism and goitre, and that lack of iodine entered into the production of both hyperthyroidism and hypothyroidism, either of which conditions provided a suitable soil in which rheumatism could flourish. He was doubtful as to any direct influence of the ovary. If ovarian deficiency were a primary cause one would expect to find rheumatism and rheumatoid arthritis chiefly during the child-bearing epoch, which was not the case. He believed the condition of the thyroid to be the principal endocrine factor.

Dr. F. G. THOMSON (Bath) considered that the close connexion of certain forms of chronic arthritis with abnormalities of thyroid activity was clearly brought out in the case of rheumatoid arthritis on the one hand, and villous (or what he would prefer to term climacteric) arthritis on the other. It was a matter of common observation that rheumatoid arthritis was very frequently complicated by symptoms of hyperthyroidism. He showed some diagrams

illustrating the correspondence between the two diseases. The close association of chronic arthritis with want of endocrine balance was also clearly shown in the case of villous arthritis, occurring in women at the menopause. This disease was usually associated with definite evidence of endocrine deficiency in the form of fibro-fatty thickening of the subcutaneous tissues, dryness of skin, and tendency to alopecia. The brawny, middle-aged woman who developed painful, swollen, and creaky knees at the climacteric formed one of the commonest types of the so-called "rheumatic" patient. This form of arthritis was so well defined, so true to type, and so closely associated with other changes incidental to the menopause, that he thought it justifiable on clinical grounds alone to regard it as climacteric arthritis.

Dr. KERR PRINGLE (Harrogate) spoke of the "atrophic" group of rheumatoid arthritis cases, in which focal infections played no part. This atrophic group was confined, he believed, entirely to the female sex, and observers had pointed out the similarity of the prodromal and early symptoms to those occurring in Graves's disease. A history of enlargement of the thyroid would often be found. The patient would often say that her symptoms were relieved during pregnancy, to return in the puerperium. The stimulation of the secretion of pituitrin by the internal secretion of the ovary was arrested by that of the corpus luteum until the time for the uterus to contract and the milk to flow. It appeared to the speaker well worth considering whether the inhibitory action of the corpus luteum on the posterior pituitary had any part in the amelioration of the arthritic symptoms during pregnancy.

#### Papers Taken as Read.

In the absence of the authors a number of papers were taken as read, to be embodied in the proceedings of the Conference. Dr. R. G. GORDON briefly indicated their nature. Dr. Kahlmeter of Stockholm discussed the sedimentation reaction, which he found to increase enormously, as compared with normal controls, in acute rheumatism and gout. The chief point of the paper was the prognostic value of this sign; until the curve of the reaction fell to normal, exacerbations and recrudescences were apt to occur. Professor H. STRAUSS of Berlin contributed a paper on the endocrine factor, which he did not regard as causal entirely; treatment by endocrine preparations did good in many conditions, but seldom alone effected a cure. Dr. Ralph Pemberton of Philadelphia recounted some experiments on the capillary circulation, and considered that a good many characteristic symptoms of rheumatic disease were due to a failure of the flow of blood through the small capillary channels. Dr. J. C. SMALL of the same city summarized his investigations on a specific micro-organism which he named *S. cardioarthritidis*, and said that with treatment by vaccines with cultures of this organism he had obtained beneficial results. Dr. Homer Swift of the Rockefeller Institute, New York, had a reasoned paper on the subject of rheumatic fever as due to hypersensitiveness to streptococcal invasion. Dr. Gordon Watson of Bath submitted some work by Dr. James Lindsay and himself, suggesting that the cause of chronic rheumatism was the result of the actions of toxins, endogenous and exogenous, and that the systemic imbalance might be initiated by any two or more of such factors as focal sepsis, mental strain or shock, systemic infection, environment and climate, endocrine imbalance, faulty metabolism, or disease of various organs. Mr. Timbrell Fisher of the London School of Clinical Medicine had a long paper on the pathology of chronic arthritis, discussing the complex pathological changes, and pointing out that in the same joint might be seen the phenomena of repair, inflammation, and new growth.

#### General Discussion on Causation.

Dr. F. J. POYNTER (London) thought it necessary still to keep an open mind as to the difference between rheumatism and rheumatoid arthritis and osteo-arthritis, and that the time had not yet come when it was possible effectively to form arthritic units, and cardiac units, and chorea units. It might be even now that the streptococcus would not prove to be the primary cause, though he thought it would.

Dr. P. LAZARUS-BARLOW (Queen Mary's Hospital, Carshalton) said that he had isolated from throat cultures of children suffering from acute and subacute rheumatism an unusual type of streptococcus, which he believed to be identical with the *S. cardioarthritidis* of Small of Philadelphia. On the whole, experiments had shown that this organism could form an endotoxin from which an anti-toxin could be produced.

Dr. L. BERTRAND (Antwerp) described some work on the anaerobic bacillus described by Achalmé thirty years ago—a polymorph microbe which could assume the coccic form. He believed that this was the cause of acute articular rheumatism. He had succeeded in isolating it from synovial fragments in chronic rheumatism, and he had treated patients with a vaccine from cultures of this organism with beneficial results. "I am in possession of the right treatment for true rheumatism, and the most effective at the present moment. These results have been corroborated by a large number of Belgian and foreign practitioners."

Dr. RUPERT WATERHOUSE (Bath) said that although he could give no statistics in confirmation, his experience of fillositis and chronic arthritis left him with the impression that a previous attack of rheumatic fever or chorea was little if at all more frequent in these sufferers than in patients admitted to the hospital for other complaints. He thought the tendency to abandon the distinction, first drawn by Sir Archibald Garrod, between rheumatoid arthritis and osteo-arthritis was to be regretted, because though many intermediate, perhaps mixed, cases were to be met with, the differences in the clinical picture and in the anatomical changes in well-marked examples of the two were so great as to leave no doubt that they had little or nothing in common.

Dr. J. B. BURR (Buxton) exhibited a bone taken from a horse suffering from osteo-arthritis, and said that one out of every eight of the horses which came to slaughter in London had what was known as "cabhorse disease." From this example he contended that trauma alone could produce arthritis, that strain on the ligaments was a factor—possibly the first factor—in the formation of bone changes, and that the heredity factor was important. Rheumatism in animals offered a valuable field for investigation.

Surgeon Vice-Admiral GASKELL spoke of the extreme rarity of the old classical rheumatic fever nowadays in the navy, also the remarkable drop in the incidence of chronic rheumatism. A similar reduction in those forms of heart disease supposed to be due to rheumatism had not been experienced.

Dr. P. WATSON-WILLIAMS (Bristol) said that the undoubted association of chronic sepsis in the tonsil with the incidence of rheumatic conditions had been well brought out by Dr. Langdon Brown. Endocrine imbalance was one of the consequences frequently encountered by those who had to deal with chronic septic infection. In these processes, going on so slowly, sometimes for years, there was ample time for clinical development to take place. At the climacteric and in pregnancy rheumatoid manifestations were apt to be more marked, and he would suggest that this was merely in many cases the result of the lessened tissue resistance incident to those phases of life giving to the focal infection, which was always present, greater opportunities of manifesting itself in characteristic lesions.

Dr. HENRY ELLIS (London) spoke on the biochemistry of rheumatism, which, he said, governed the whole situation. In endocrine rheumatism one did not get any disturbance of the acid-base equilibrium in the urine. If one found no variation of the acid, no increase of the sulphates, no diminution of the phosphates, one could be almost absolutely certain that it was the endocrine form of rheumatism.

Dr. G. HOLMES (Harrogate) described investigations on fifty hospital cases suffering from chronic arthritis, not all of one type. To his surprise he found no evidence of hypo- or hyper-thyroidism as shown by the basal metabolic rate. It was known that clinically the administration of thyroid was beneficial in rheumatoid arthritis, but it was of some interest to be able to take a series of fifty cases and find that they had normal metabolic rates.

The session closed with a few remarks in French by

Professor PISANI of Florence, who brought to the gathering the felicitations of his Italian colleagues, and stated his view that there was a positive relation between chronic rheumatism and disorder of the endocrine system.

#### THE TREATMENT OF RHEUMATISM.

Sir PARQUAR BUZZARD presided over the final session, remarking that his brother regius of Cambridge had accepted responsibility for the causation of rheumatism, so that surely Oxford could shoulder the burden of its treatment. True, as causation preceded treatment, the older university might have claimed the previous session for its own, but in this particular instance it was felt that the miasmatic properties of the fen country established a right of precedence which could not be disputed. "How is it that you doctors have never discovered a cure for rheumatism?" was a rebuke not infrequently addressed to them; and the only faithful reply must be that the more they knew about many diseases the less they knew about their cures. The problem of rheumatism was highly complicated, and not simplified at all by any attempt to bring all conditions blessed with that name into one pathological category. The problem involved in treatment was the problem of causation, the proper assessment of causative factors, and the requisite knowledge to prevent and destroy their influence. In the long run it was a problem of preventive medicine. Meanwhile, spa treatment was invaluable from several points of view, relieving suffering, preventing crippling, and offering opportunities for research.

#### Prevention of Chronic Rheumatism.

Dr. R. L. J. LLEWELLYN, in a paper on the prevention of chronic rheumatism, said that if the fundamental truth that man and his environment were one organic whole had never been lost sight of, the salient role of the skin in rheumatism would never have been minimized. The primary signs of physiological inadequacy in rheumatic subjects were instability of the blood supply of the skin and also sweat secretion. This pointed to what should be a basal principle in prophylaxis—namely, the maintenance of the functional efficiency of the skin. Many textbooks on acute and chronic rheumatism contained not a word about skin hygiene, although the skin and mucous membrane were our first line of defence against weather changes. The maintenance of the skin's efficiency was best achieved by hydrotherapy, with alternating applications of hot and cold water to the skin surface. Dr. Llewellyn went on to discuss the principles underlying the prevention of muscular rheumatism, including the maintenance of a due balance between food intake, muscular output, and skin efficiency, the avoidance of "occupation misfits," the recognition of "motion study" as essential to scientific management in industry, the avoidance of fatigue and the wrong use of muscles, the arrangement of rest pauses, and the necessary hygienic conditions in the workroom. He also spoke of the prevention of rheumatoid arthritis, the key to which, he considered, consisted in recognition and treatment of the pre-arthritis or premonitory phenomena.

#### Rheumatic Infection in Childhood.

Dr. F. J. POYNTER of University College Hospital, who dealt with the treatment of acute rheumatic infection in childhood, declared himself to be no believer in the treatment of young children with acute rheumatic carditis by means of salicylate of soda. He had instead treated the severe forms of rheumatic carditis in children by the ethyl-ester of methyl-phenyl-cinchoninic acid, known by the proprietary name of "tolsin." He had used this drug now for some four years in very grave cases of young children in whom there had been pancarditis and often also nodules, arthritis, and chorea, with general toxæmia. He mentioned certain objections to salicylate when it was pushed, including possibly death from coma, also depression, which he had never seen follow from the cinchonic acid preparation just mentioned. He would not pretend that salicylate of soda had no beneficial effect in rheumatism, for he knew that it had, but whatever the action might be it was not specific, as quinine was specific to malaria. The drug he had mentioned was milder in action,

but, he believed, clearly of value, and he recited a number of cases in which treatment had been carried out with the ethyl-ester with good results, and without causing any anxiety on account of troublesome symptoms.

Dr. A. P. THOMSON of the Children's Hospital, Birmingham, dealt with the organization of institutional treatment for rheumatic children. Until recently, he said, no organized system of treatment of rheumatic children existed; the disease had certainly attracted the attention of the school medical service as a frequent cause of prolonged absence, but nothing was done by any public health authority to remedy the evil that the inquiries disclosed. The ordinary case might require, at one time or another, three different types of treatment: in hospital during the acute phase; in a convalescent home, where nearly all the time might be spent in bed; and finally, in an institution in which the child's return to activity could be regulated under careful supervision. In Birmingham children with acute manifestations of rheumatism were admitted to the Children's Hospital in the ordinary way, were later transferred to a convalescent home, whence they went in batches to Baskerville School, a special residential school, controlled by the local education authority. Dr. Thomson gave an illustrated description of this institution, its special equipment, and its daily routine. In showing a group of the children playing cards he mentioned that card-playing was quite a valuable corrective for chorea, because, if the player had chorea too badly, he could not help showing his hand to his opponent!

#### Vaccines: their Use and Abuse.

Sir WILLIAM WILLCOX, in speaking on the treatment of the underlying infection, said that in his experience of hospital practice one did not meet to anything like the same extent to-day with the virulent cases of rheumatic fever in children which were so common thirty years ago, an improvement which he attributed largely to the development of school hygiene. He went on to speak particularly of vaccine therapy. Vaccines, he said, should not be given until the case had received the fullest clinical investigation, and any existing foci of infection had had appropriate treatment. An abuse of vaccine therapy was the administration of vaccines in cases of chronic rheumatism where obvious foci of infection were present—for example, septic teeth or tonsils. Vaccines were contra-indicated where "sensitization" to the toxins from the infection existed, also in exophthalmic goitre, if this was associated with chronic rheumatism. They were of value in chronic rheumatism when any gross focus of infection had been removed and the toxic process was being carried on by the chronic infection of a mucous surface with its accompanying glandular tissue. It was advisable to begin with a vaccine of weak strength—say 5,000,000 per c.cm.—and after a preliminary course to proceed with a stronger vaccine of, say, 50,000,000 per c.cm. Any evidence of symptoms of sensitization was an indication for discontinuance. Stock streptococcal vaccines made from other patients were in his experience far inferior to autogenous vaccines. Antistreptococcal serum was not indicated in cases of chronic rheumatism. Protein-shock therapy had been disappointing.

#### Physical Treatment.

Dr. J. CAMPBELL McCURE of London divided physical treatment into two groups: (1) exercises, baths, and radiotherapy, which effected alterations in metabolism and raised the general resistance to infection, and (2) massage, local applications of heat, douches, and manipulation. The value of the various forms of physical treatment was much debated. A great deal depended on the way in which they were applied. No form of physical treatment was more stupidly applied than massage. The good effects of general massage were often nullified by heavy massage of the abdomen to counteract the tendency to constipation, on the extraordinary idea that one could produce good effects by the rough handling of the colon itself. Baths, again, improperly applied, could be dangerous to the patients—for example, if given at too high a temperature having regard to the circulatory and metabolic capacity. He emphasized the importance of electrotherapy in the treatment of all

wasted and atonic muscles in rheumatic disease. Massage and baths could do much, but without the addition of electrical treatment a great deal of time was wasted. In this condition, as in others, no one form of physical treatment was enough. The Plombières treatment was extremely useful in cases where rheumatic manifestations were associated with a chronically inflamed and infected colon; it should, however, be administered by careful and skilful persons. He had known its misuse—in combination with an excessive diet of lactic oats—produce in a person, who at the beginning of treatment was as reasonably healthy as most nervous persons living under considerable strain could be, an obstinate mucous colitis. He had always found that the best results were obtained by a combination of various forms of treatment.

Professor ISIDORE GUNZBURG gave an account of the Brugman Hospital at Brussels, which is an antirheumatic centre, with an elaborate physiotherapeutic service. Since it started this centre had received about 230 patients, and he claimed that in 50 per cent. the rheumatic pains had disappeared altogether, and in 60 per cent. the movements had been considerably improved.

#### *The Scope of Surgery.*

A paper on the scope of surgery in the treatment of degenerative arthritis was to have been read by Mr. Max Page, but he was unable to be present, and this phase of the subject was dealt with very briefly by Mr. WHITCHURCH HOWELL, who described the various methods of treatment open to the surgeon in these cases. These methods included traction, mobilization with or without traction, arthrodesis, and in a limited number of cases arthroplasty, or the formation of a new or false joint. By means of lantern slides he indicated the types of cases in which these various procedures were suitable, and laid stress upon the fact that in no case should manipulation be performed without x rays. Arthritis could be prevented, and very often could be cured in its early stages.

#### *General Discussion on Treatment.*

Dr. WARREN CROWE asked why vaccine treatment was not universally used. He had found great benefits follow from it. Faulty technique was possibly a reason why it was put on the shelf. The first principle of treatment—the small dose—was too often disregarded. He had cases under treatment at the present time which got a very definite reaction with a twentieth part of a million of streptococcal vaccine. Rarely should any case start with more than 500,000, and 2,000,000 might easily be the maximum tolerated. He pleaded that those who had the treatment of rheumatic cases should try vaccines again; the method had the great advantage that it was suitable for the general practitioner's use in his own surgery.

Dr. C. W. BUCKLEY (Buxton) said that it had been his experience for many years to see patients drawn from manufacturing districts suffering from various rheumatic disorders largely attributable to their environment. Frequently they had spent weeks or months in hospitals in their own neighbourhood without benefit, but after treatment in a large and well-equipped spa hospital they greatly improved. Climate, as well as food and mode of life, had a great influence in promoting recovery. No student of the treatment of rheumatism could afford to be ignorant of the great spa hospitals and the wealth of clinical material they presented for study, and a conference of that character would be incomplete without some consideration of spa treatment, the most ancient of all methods.

Dr. VINCENT COATES (Bath) gave some personal experiences of the treatment of infective arthritis. The essentials of treatment were the raising of immunity and the correction of biochemical abnormalities. The condition of a patient in the acute or subacute stage of the disease should be regarded in much the same light as that in which it was customary to regard pulmonary tuberculosis or Hodgkin's disease. In the chronic stage in which infection died out and there was apparently no likelihood of recrudescence, the patient should be regarded in much the same light as that in which it was customary to regard sufferers from other diseases giving end-results in joint and bone—namely, as an orthopaedic case. He described

the thorough examinations whereby biochemical and bacteriological anomalies should be sought for and adjusted in an attempt as far as possible to raise the immunity of the individual. With regard to the joints themselves, in the acute stage rest in splints was indicated to obviate the well-known deformities. No joint which was hot or tender should be manipulated. In the subacute stage much could be done by hydrotherapy and splinting; a mud-pack to, say, the knee, followed by a deep bath, was an excellent prelude to the readjustment of an extension splint. Manipulation under anaesthesia could be safely indulged in in a large number of chronic cases. Care must be taken that not too much force was used. Spa treatment was useful throughout the course of the disease.

Dr. HANS JANSEN (Copenhagen) gave the following general principles of his treatment:

**Lumbago:** Radiant heat or hot air, followed by massage.  
**Sciatica:** In first stages, bed; afterwards warm fomentations in woollen blankets; later radiant heat and massage.  
**Subacute polyarthritis:** Very cautious use of physical treatment.  
**Chronic polyarthritis:** Hot air, steam bath, diathermy, active and passive exercises.  
**Osteo-arthritis:** Vigorous warm treatment followed by energetic massage and exercise of the muscles, but never massage of the affected joints (hip or knee) themselves.

In some further discussion Dr. ALEX. CAWADIAS (London) mentioned that he had found his best results with common stock vaccines. In vaccine therapy he thought the method of procedure was more important than the material used. He believed there was a great future for shock therapy. Dr. DONALD BRIMS (London) spoke of the effects of introducing oxygen beneath the skin and of treating rheumatic cases with emanations of radium and thorium. He had seen results from these applications, made at the Pasteur Institute in Paris, which were amazingly good. With the help of lantern slides he described the technique. Dr. P. WATSON-WILLIAMS (Bristol) emphasized the difficulties that confronted one in the endeavour to detect focal infections. The history of the patient's symptoms was most valuable. One should persevere in the search for focal infection, because, if this could only be found, a very considerable step had been taken towards stopping the progress of the lesions.

Sir FARQUHAR BUZZARD, in closing the session, said that it would be impossible at the moment to estimate the results of the discussions, but if no other immediate results were forthcoming, the exchange of views could not fail to stimulate new interest in the subject, new ideas for research, and new hope for the future treatment of rheumatism in all its phases.

Sir GEORGE NEWMAN, president of the Conference, proposed a resolution, which was seconded by Dr. R. A. FLEMING, and heartily carried, thanking the Mayor and municipal authorities of Bath for their most lavish hospitality, and acknowledging also the convenient arrangements made by the local Organizing Committee and by the director of the City Baths (Mr. John Hatton). Sir George Newman added that he proposed to take the earliest opportunity of presenting to the Minister of Health and the President of the Board of Education a copy of the proceedings of the Conference.

#### *CIVIC ENTERTAINMENT.*

On the evening of the first day of the Conference a civic reception to the visitors was given at the Pump Room. About 400 guests were received by the Mayoress (Madame Sarah Grand)—in the absence, through illness, of the Mayor, Alderman Chivers—and by Dr. F. G. Thomson, chairman of the Organizing Committee. A most excellent programme was provided by the Pump Room Orchestra, and supper was served in the Roman Promenade and in the Museum.

The reception was preceded by a dinner at the Guildhall, over which the Mayoress presided. The distinguished company included nearly all those taking a prominent part in the work and arrangements of the Conference. Among the guests were Lord Dawson of Penn, Sir George Newman, Sir Walter Kinnear, Sir Farquhar Buzzard, Dr. R. A. Fleming (President, Royal College of Physicians, Edinburgh), Sir James Berry (President, Royal Society of

Medicine), Dr. H. B. Brackenbury (Chairman of Council of the British Medical Association), Dr. J. Van Breamen (Honorary Secretary of the International Committee on Rheumatism), Sir Squire Sprigge (Editor of the *Lancet*), and Dr. N. G. Horner (Editor of the *British Medical Journal*).

The speeches were brief, as an early adjournment was made to the Pump Room for the reception, but the health of the city of Bath was proposed in an eloquent oration by Lord Dawson of Penn, who spoke of the distinctive qualities of this beautiful city of the West, which had survived time and change in so wonderful a way. "Its Roman remains bear witness that its beauty of design, its distinctive adornment, have ever been its pride; and enshrined in this fabric of beauty there is left to this day that spirit of independence, that civic consciousness, which were the mainstay of the Roman Empire—qualities which, we note with pride and rejoicing, are still active and vivid in the Bath of to-day." It was, however, the eighteenth century, Lord Dawson continued, which gave us a Bath conscious of its gifts and resources. Men of genius raised from amongst its craftsmen worked together as if inspired on a harmonious town-planning, and thus was set a perfect stage on which the sparkling comedy of manners was soon to be played. After the passing of Beau Nash and his regime Bath went for a while into the shade, but its spirit and tradition survived, and to-day it was to be seen and admired of all men—a spa unsurpassed in equipment and direction, in vision and civic purpose, and full and overflowing hospitality.

#### LUNCHEON BY THE BATH DIVISION.

In the interval between the morning and afternoon sessions on May 11th the medical visitors to Bath were hospitably entertained to lunch at the Grand Pump Room Hotel by the Bath Division of the British Medical Association, under the chairmanship of Dr. R. G. Gordon. In proposing the health of the guests Dr. Gordon explained that, although the Conference was not in any way a B.M.A. function, its Organizing Committee was in fact a subcommittee appointed by the local Division of the Association, and he and his immediate colleagues (Dr. Thomson, Dr. Waterhouse, and Dr. Coates) had received much help and encouragement from the headquarters of the Association. It was therefore with particular pleasure that they welcomed the Chairman of Council (Dr. Brackenbury) at the Conference and at this luncheon party. The toast was responded to by Sir Farquhar Buzzard, who expressed the appreciation of himself and his fellow guests for the boundless hospitality with which they had been received by the city and the medical profession of Bath. Sir Humphry Rolleston proposed the health of the Division, and spoke of the affection with which Bath was regarded throughout the profession. He coupled the toast with the name of Dr. F. G. Thomson, President of the British Medical Association in 1925-26, and now chairman of the Organizing Committee for this Conference, whom everyone was delighted to see restored to full health and vigour. Dr. Thomson acknowledged the compliment, and three of the distinguished medical visitors from abroad addressed a few words of greeting and thanks to their colleagues at Bath.

#### BALNEOLOGICAL MEETING AT BATH.

On the day following the Conference on Rheumatic Diseases the Balneological Section of the Royal Society of Medicine held its annual meeting in Bath. Members of the Section and a number of others who had attended the proceedings on Thursday and Friday assembled in the Pump Room at 9.30 a.m. on Saturday for a visit to the hot mineral baths, and saw demonstrations of treatment on appropriate cases in the various establishments. At 11 o'clock clinical demonstrations were given at the Royal Mineral Water Hospital by the physicians of the hospital, Dr. Rupert Waterhouse showing cases of osteo-arthritis, Dr. J. Lindsay cases of gout, Dr. Vincent Coates cases of infective arthritis, Dr. R. G. Gordon cases of fibrositis, and Dr. A. Gordon Watson cases of sciatica. In the afternoon the visitors went on a motor tour of Bath and its environs, by invitation of the Hot Mineral Baths Com-

mittee. This was followed by an inspection of the Roman Thermae, and tea on the Roman Promenade; in the evening a concert was given by the Pump Room Orchestra. Sunday was mainly given up to charabanc excursions to the Mendips and Cheddar, returning by way of Wells, and in this manner four very enjoyable and instructive days were rounded off.

#### SUNLIGHT IN MODERN MEDICINE.

##### *Clinical Experience in England and Scotland.*

A CHADWICK public lecture on "Sunlight—natural and artificial—and its use in modern medicine" was given by Dr. Walter Elliot, M.P., Under Secretary of State for Scotland, on May 15th, at the British Medical Association House, Tavistock Square, London.

Dr. Elliot referred briefly to the development of the medical employment of sunlight, and said emphasis was now laid upon the constructive or healing power of radiation, particularly of short-wave (ultra-violet) radiation, but the effects were still a matter of active discussion. Public authorities were making extensive use of this method of treatment, and their experience already formed a large body of clinical opinion which would well repay attention.

In England and Wales, by the year 1926, 64 centres had been established by local authorities directly, and 56 by voluntary agencies, to which local authorities sent cases. In addition, light treatment was carried out at 11 school clinics; at 7 hospitals, and at numerous centres established by voluntary agencies to which children were sent. In Scotland there were 30 centres in sanatoriums and hospitals belonging to local authorities, and 6 in private sanatoriums. There were also 21 centres under child welfare schemes, and it might be taken that all the larger and several of the smaller voluntary hospitals possessed installations. There were also some installations in the larger Poor Law hospitals. This gave a total of over 170 centres in all.

Experience in England showed that the best results were obtained in treating (1) lupus, (2) certain skin conditions, (3) rickets, and (4) superficial lesions in surgical tuberculosis. The general conclusions of the reports received by the Ministry of Health were that, while ultra-violet light was by no means a general specific for all forms of disease, it formed a useful accessory therapeutic weapon, especially in combination with other methods tested and approved by time; further, that the time was not yet ripe for any co-ordinated classification of results. The Scottish verdict was somewhat more enthusiastic. A special report by the Board of Health stated: "Its value in the less severe forms of non-pulmonary tuberculosis is unquestioned. In pulmonary cases the results have not been discouraging, but much more work will require to be done. In child welfare work on the whole the results are most encouraging. They fully justify the expense and labour involved in providing this method of treatment."

The explanation of these differences of opinion, Dr. Elliot continued, might be found in the ultra-violet radiation recorded in the respective countries. In Ventnor the average daily readings for November and December, 1926, were 2.35. In Edinburgh the readings were nil for the whole three months between November, 1925, and March, 1926, and even in March and April the readings only averaged 1.1. It was obvious, therefore, that one would expect a supplementary source of ultra-violet light to show more marked results in the North than in the South. In the short-wave radiations a therapeutic factor of considerable potency was available, although its working was by no means clearly understood. He wished to draw attention to a passage from one of the Scottish reports, where the observers pointed out that "its therapeutic properties are in the main limited to conditions of growth or function that are below normal. The increase of body weight, improvement of mineral content of the blood, increasing of the bactericidal power of the blood, took place when individuals were below normal, but no corresponding effect took place with normal individuals." This view was strikingly emphasized by experiments carried out by Henderson in Aberdeen.

Dr. Elliot concluded that irradiation was of value in removing a condition which, although widespread in modern life, was still a symptom only. The illness of which this condition was a symptom was deficiency in diet, lack of accessory food factors, vitamins, or mineral salts. Effort should be directed to the removal of the root cause, and the work of the ultra-violet-ray therapist would come into close relation to that of the nutritionist. The fundamental requirements of the normal being were yet far from being met; these were fresh air, fresh water, fresh food. Till these were met the administrator would have a part to play in the twentieth century not less important than he had in the nineteenth.

# British Medical Journal.

SATURDAY, MAY 19TH, 1928.

## RHEUMATIC DISEASES.

A CONFERENCE on Rheumatic Diseases was held at Bath at the close of last week, under the presidency of Sir George Newman, Chief Medical Officer of the Ministry of Health. We think we may say that the objects of this conference have been attained. As the president remarked, the chief affliction of Great Britain in the twentieth century would seem to be rheumatic disease, as tuberculosis was of the nineteenth century. For many years a number of individual workers have been engaged on the study of rheumatism, and the time has now come when their several results and theories may with advantage be correlated and discussed, so that the medical profession may see its way to tackle this problem systematically. It will occur to those who read the account of the papers and discussions published elsewhere in our present issue, and the full proceedings which will appear shortly in book form, that nothing startlingly new has been given to the world, and perhaps this could hardly be expected. What seems to us to have been the chief note of the Conference is in a sense paradoxical: the lack of similarity between acute rheumatism at one end of the scale and osteo-arthritis at the other was stressed by several speakers, while others insisted that there might be more justification for the common term "rheumatic" than has been hitherto supposed. It must be the purpose of future research to resolve this paradox. The maladies to which the human race is heir may be roughly divided into two groups. Those in the first group are due to specific causes, they present a fairly constant clinical picture, and sooner or later a specific remedy is found; as an example may be mentioned the malarial plasmodium and quinine. Those in the other group have a complicated etiology, their clinical manifestations are manifold, and there is no certain remedy which can be used effectively, though the number of patent medicines claiming to cure is immense. To this group rheumatism unquestionably belongs, for even in the acute disease the specificity of salicylates is being called in question.

It seems obvious that if rheumatism is to be classed in the second group of maladies the problem presented must be envisaged as a biological one, and not as symptomatic. Pain and affection of the joints may be the most striking features from the subjective and objective standpoints respectively; but the physician in the future must not let his attention be diverted by them from the appreciation of what lies behind. Nor does he lack reasons for taking the wider view, for in the insured population alone, comprising not more than one-third of the whole, the cost of rheumatism in money is upwards of £17,000,000; and, if the late effects of rheumatic carditis in children are taken into account, the rheumatic group of diseases must be reckoned one of the principal causes of death in the community.

So far as acute rheumatism and rheumatic infection in childhood are concerned, the war against these conditions must begin in infancy. Although heredity does not seem to play very much part, the constitu-

tion of the child undoubtedly does. Rheumatic infection is apt to occur in the "nervous child," and when infection has taken place the "nervousness" is increased in a vicious circle. Diet is of considerable moment, for the pre-rheumatic child tends to be intolerant of carbohydrates and is often deficient in vitamin B. The lymphoid system of these children is poor in quality, and soon becomes converted from a defence against micro-organisms into an absorbing surface for the microbes and their toxins—hence the importance of close attention to the hygiene of tonsils and adenoids; while failure of the intestinal lymphoid structures is responsible for the toxic debilitated state found in children before and after actual infection has taken place. The endocrine system is ill-balanced, as is shown by two phenomena which are familiar after infection has taken place—namely, the irregular and abnormal sweat secretion, and the tendency to hyperpyrexia, which may often be controlled by insulin. The skin is inefficient in its response to cold and damp, which may explain the marked effect of damp houses on the incidence of this disease. There is also a sensitization of the tissues to certain micro-organisms and their toxins, particularly to the *Streptococcus viridans* and its allies, and a phasic variation between this sensitivity and a relative immunity may occur all through childhood, explaining the frequent remissions and exacerbations. This may culminate in an absolute immunity in adult life.

Opinion is still divided as to the causal organism, though most observers admit that it is a streptococcus, which is probably a saprophyte in ordinary circumstances, only becoming pathogenic when sown on a suitable soil. Evidence is accumulating that such streptococci of low virulence may induce a specific tissue reaction in the form of the nodule analogous to the tubercle and the gumma. Various special strains of streptococcus which are believed to be the specific causal organism have been described; the most recent is that termed in America the *Streptococcus cardio-arthritis*. Although not an infectious disease, evidence is not wanting that under certain conditions it may be mildly contagious, especially in the stage before clinical signs have become manifest. If serious complications are to be avoided, not only must rest and appropriate treatment by salicylates or other drugs be given during the active stage, but convalescence must be managed with the greatest care. The rheumatic child must not go back to the rough-and-tumble of ordinary school life for at least a year after the attack, but complete rest in a convalescent home is not generally necessary for more than six weeks; therefore the provision of special schools is a necessity. Since the main incidence of rheumatic infection is on the elementary school child, the charge for these schools, if and when they are established, will presumably be on the State.

When we turn to chronic rheumatism the first thing that strikes the eye is the complexity of the picture. In this picture, however, certain features are found which resemble those of acute rheumatism: the disordered skin reaction, the disturbance of endocrine function, and the specific tissue reaction to low-grade streptococci—namely, the nodule. Like acute rheumatism, these conditions—whether infective arthritis, fibrositis, or osteo-arthritis—must be looked upon as biological deviations, as system diseases. The first two have their seeds in early life, while the last may be a part of the general deterioration of advancing years affecting joints which have been weakened by strain, trauma, or infection, acting separately or together. In the investigation of these

diseases it is necessary to pay attention to the biochemical constitution of the patient, and deviations from the normal will often, if not always, be met with. The commonest are disturbances in sugar tolerance, alterations in the pH values of the body fluids, and abnormalities in the metabolism of calcium, phosphorus, and sulphur. The endocrine organs, and more particularly the thyroid gland, are as a rule not fault, hypothyroidism being associated particularly with fibrositis and chronic synovitis, and dysthyroidism with infective arthritis. Foci of infection are of great, but not exclusive, importance, and faulty elimination must also be taken into account. Treatment of these conditions may be grouped under six heads: (1) removal of septic foci by surgical or medicinal means; (2) promotion of elimination by means of physiotherapy and hydrotherapy, more particularly by the skin; (3) establishment of immunity from the invading organisms by means of vaccines, given with due discrimination in respect of dosage and interval; (4) induction of tissue reactions by various forms of shock therapy; (5) correction of endocrine imbalance by administration of suitable extracts; (6) massage and other physical and hydrological methods which aim at the alleviation or removal of local lesions. If the case comes under treatment reasonably early such methods warrant a favourable prognosis. They can be carried out at a well-equipped hospital or clinic, but probably the spa is still the best centre for their administration. Physical treatment is expensive, and therefore often beyond the reach of the industrial population, unless the State, through the national health insurance scheme, extends this opportunity for treatment to its beneficiaries. Mention should also be made of the place of surgery in the treatment of rheumatic diseases. In the first place, orthopaedic principles must be applied in the maintenance of posture of joints and muscles; and secondly, when the case has been neglected, or when in spite of treatment contractures and deformities have resulted, a helpless cripple may be restored to comfort and usefulness by means of arthrodeses, arthroplasties, and kindred operations.

Such appears to be the gist of the contributions made in the course of three strenuous sessions at Bath. We believe that the promoters of the Conference may feel confident that they have collected a mass of material which will stimulate further research into these difficult problems of causation and treatment, and point the way to the more efficient application of what is already known.

### IMMUNIZATION AGAINST INFECTIOUS FEVERS.

THE need for taking stock of new procedures for the prevention and treatment of disease arises from time to time, and in the opening pages of our present issue there appears the report of an opportune lecture by Dr. Monckton Copeman, in which he surveys recent developments in immunization against diphtheria, scarlet fever, and measles. In connexion with the treatment of diphtheria it may be wise to recall that these new methods of prophylaxis in no way invalidate the wise rule of practice that when a patient shows membrane in the throat and a suspicion of diphtheria arises, impelling the doctor to take a swab, antitoxin should be given then and there. For the prevention of the disease Schick testing and active immunization have proved their utility, and in the case of nurses in diphtheria wards and of children in residential

institutions in which diphtheria is endemic, sufficient experience is now available to justify action. None of these nurses should be Schick-positive, nor should the children, unless the parents refuse the protection offered. In regard to the general population it has often been said that, though any idea of compulsion will be equally distasteful to medical administrators and to the public, every parent who desires protection for his children should have ready access to an immunization centre. Many public health authorities already meet this demand.

The Dick test and active immunization against scarlet fever have clearly come to stay, though the exact field they will occupy and the details of the optimum methods in their application have not yet been finally settled. Evidence from Benson and others indicates already that the personnel in scarlet fever wards can be almost entirely protected against the disease. In infected residential schools and kindred institutions in which scarlet fever is endemic, these measures, properly applied, give the responsible authority a confident control of the position. In an emergency a dose of 5 c.cm. of antitoxin will protect contacts for from seven to ten days, and allow time for other appropriate measures to be applied. Here again the busy practitioner will feel that his course in the treatment of the disease is clear. When he is called to an obvious case of scarlet fever he need not feel obliged to remember that the Dick test and the Shultz-Charlton blanching test will be positive, and that haemolytic streptococci are present in almost pure culture in the throat—he may be glad enough to recall these facts when in doubt about a diagnosis in a difficult case or during a troublesome atypical epidemic in a school—but he will remember to give intramuscularly an adequate dose of scarlet fever antitoxin at once if the patient is severely or even moderately ill.

The vexed question of the interrelation of the haemolytic streptococci must at present be left to the immunologists. It is interesting that Parish and Okell<sup>1</sup> find scarlet fever antitoxin more useful in neutralizing, in the rabbit, the haemolytic streptococci of puerperal and streptococcal septicaemia and erysipelas than the autogenous serums. Their suggestion that scarlet fever antitoxin should be given an adequate trial in the treatment of all infections caused by the haemolytic streptococci has a certain amount of clinical support, and will appeal to many practising physicians.

We are glad that the use of convalescent serum in the fight against measles has again been brought before the medical public.<sup>2</sup> To the child aged less than 3 years, and particularly to one already struggling with some other illness, an accidental exposure to infection with measles is a serious matter, for at this age measles is a grave menace. The knowledge that 5 c.cm. of human convalescent serum given in the first four or five days after exposure will completely protect such an infant, or will give safety to a schoolboy due to sit for an important school examination, and that the same dose given between the fifth and ninth day after exposure will almost certainly allow a very mild and transient attack of measles to develop with subsequent active immunity, will often be gratefully recalled by the busy practitioner. Yet it is disturbing for him to have this knowledge but to be unable at present to get supplies of the serum when required. Lord Monckswell, in a letter printed in the *Times* on May 4th, called attention to a case in which it was impossible to procure the serum in London, and a

<sup>1</sup> Parish, H. J., and Okell, G. C.: *Lancet*, 1928, i, 745.

<sup>2</sup> See *British Medical Journal*, 1928, i, 189.

telegram had to be sent to Paris. A convalescent adult can easily spare 300 c.cm. of blood. The volunteer can be told, without exaggeration, that the thirty doses of serum resulting will certainly remove much anxiety from many troubled mothers, and may quite probably save the lives of a number of infants. Such a presentation of the case should make a powerful appeal to many convalescents. A healthy adolescent, 12 to 15 years of age, could easily spare 100 to 150 c.cm. of blood, and Dr. Canti's<sup>1</sup> success in obtaining small supplies from volunteer patients suggests that the appeal will often succeed. It would be a great source of satisfaction if the Medical Department of the Ministry of Health, which has done so much already in other directions, could overcome the difficulties in the way of organizing a central supply of convalescent serum for urgent cases of measles.

### ENDOSCOPY.

THE originators of endoscopy could scarcely have foreseen the extent to which it has proved to be capable of development, although its introduction into the practice of medicine is of relatively recent date. It is natural that its foremost and most dramatic triumphs should be those in which life has been saved by the extraction of foreign bodies from the air passages or oesophagus, or even from the stomach, but in the past few years its application to the diagnosis and treatment of disease has also made striking progress. Of those who have devoted themselves to the study of this highly specialized work it is no overstatement to say that Dr. Chevalier Jackson and his associates in Philadelphia have accomplished more than all other contemporary workers combined. It would seem, indeed, that in so far as the extraction of foreign bodies is concerned Dr. Jackson has no further fields to conquer. The first edition of his *Bronchoscopy and Esophagoscopy* was an abstract of the large work *Peroral Endoscopy*. The latest edition of the smaller work<sup>2</sup> is on the same lines, but the scope is broadened; there are fresh details, and it contains, among other new matter, an interesting account of the course directed by Dr. Jackson at the University of Paris. He tells us that "when *Peroral Endoscopy* was published in 1914 five cases were mentioned as beyond the limits of bronchoscopy." "Every one of those cases would have been quite simple to-day," and the only exception that he now admits "is in the case of foreign bodies that are so small as not to be localizable." "The impossible in bronchoscopy for slender foreign bodies, such as pins, in minute bronchi at the periphery of the lung" has been practically eliminated. Of the method generally Dr. Chevalier Jackson says "it is all a matter of plumbing." The metaphor scarcely does justice to an art which has been brought to such a stage of refinement, though the meaning is clear enough, but if there are any general principles involved this is about the only one. The summit has been reached by the detailed study of a large number of cases, by the selfless co-operation of a number of fellow workers, both colleagues in other branches and assistants, and by the ceaseless adaptation of instruments to meet the infinite variations in the problems which demand solution. Perhaps this last consideration is the most important of all, for endoscopy is an art which lends itself in no way to makeshifts or brilliant improvisation. Everything depends on proper instruments and assistance, and for the inexperienced operator it is better to leave a case alone than approach it either with an insufficient equipment or, it may be added, without reading Dr. Jackson's book. "The

motto of the endoscopist should be, 'I will do no harm.' " *Primum non nocere* is a rule of general application, but the account of the state in which many patients reach the Bronchoscopic Clinic in Philadelphia after unsuccessful endoscopies elsewhere shows that it applies more forcibly here than almost anywhere else in medicine or surgery. It would be impossible, therefore, to exaggerate the benefit resulting from the training which a large number of the younger school of laryngologists have received at the Bronchoscopic Clinic.

### THE FOUNDER OF THE RED CROSS MOVEMENT.

HENRI DUNANT, the centenary of whose birth was celebrated at Geneva on May 8th, founded the Red Cross movement, which ranks very high among the international organizations associated with the name of this Swiss city. Geneva was, in a sense at least, the home of Calvinism; it was the domicile of the now forgotten First International; it is to-day the seat of the League of Nations; but no ideal or enterprise which has originated in Geneva has gained such world-wide approval as has the Red Cross. Dunant was a member of a patrician family of the Republic and Canton of Geneva, and appears to have derived his interest in the care of the sick and wounded in war from his admiration for the achievements of Florence Nightingale in the Crimea. In 1859, when France, Austria, and Sardinia became involved in war, he went to Italy, and at the battle of Solferino assisted in the removal and care of the wounded. Three years later he published his impressions under the title of *Souvenirs de Solferino*, and in his conclusion uttered the hope that before long the treatment of those who suffered in war would be governed by a general agreement providing for their relief irrespective of their nationality. Dunant's suggestion having been favourably received and actively supported in Switzerland, he undertook a missionary tour of various European capitals to win wider support. In October, 1863, a conference of representatives of various Governments was held at Geneva, and certain fundamental principles were enunciated, the effect being to embody in international law the idea of respect for the wounded and of a measure of immunity for medical personnel and material. The Geneva Convention came into being in the following year, when delegates of sixteen countries, at an assembly convened by the Swiss Federal Government, agreed to its provisions and adopted the emblem of the red cross on a white ground, the symbol being the Swiss Federal colours reversed. This side of the movement gave the wounded a definite title to protection, but the other side, which resulted in the creation of the Red Cross societies, has been of equal importance. The establishment of the first Geneva committee, the International Committee of Assistance to the Wounded, was followed soon afterwards in Great Britain, for example, by the inauguration in 1870 of the National Society for Aid to the Sick and Wounded in War—the parent of the British Red Cross Society. It is unnecessary to recall the services to humanity rendered by the International Red Cross Committee, notably in connexion with prisoners of war, and the various national bodies during the late war. Since then Red Cross work has taken a new orientation, and to-day the chief concern is with the casualties, not of war, but of peace. In a hundred ways, less dramatic than those associated with trenches and battlefields, but no less important to suffering men and women, the humanitarian tradition which inspired the founder of the movement persists. Henri Dunant has not lived to see the full fruition of his work, for he died in 1910, and his later years were overshadowed by sickness and financial anxiety. It is pleasant to recall that he was not altogether unrewarded and unrecognized, for in 1901 he was the recipient of the first Nobel Peace Prize, and on several occasions foreign orders were bestowed upon him.

## MULTIPLE EXTRACTIONS OF TEETH.

It is a curious fact that, despite the horror universally evoked by the sight of the dentist's forceps, tooth extraction is still widely regarded as a very minor, almost contemptible, operation. "Oh, whip it out with a whiff of gas!" is the attitude of many people, both among the laity and among members of the medical profession—as if shock and sepsis were unknown after operations in the mouth. In a post-graduate lecture delivered lately at the Royal Dental Hospital of London<sup>1</sup> Dr. Harvey Hilliard, senior anaesthetist to that institution, urged the importance of a more serious view of tooth extraction, especially of multiple extractions. Dr. Hilliard has thirty years' experience both of general practice and of dental anaesthetics, and may claim to speak with authority. He holds that multiple extraction of teeth should rank as a major operation, to be performed in a nursing home or at the patient's own residence, after due medical examination (including blood examination) and proper preliminary preparation; and that an adequate period of convalescence should be arranged for, and the patient immediately fitted with temporary dentures, so that he can partake of the diet he has found by experience best suited to him, and thus be saved from the risk of being half starved, with its inherent danger of consecutive disease. As the result of his own experience Dr. Hilliard finds that patients suffer much less, as regards both shock and sepsis, if all the teeth are taken out on one occasion. Operating at home, as opposed to extraction in the dentist's room, allows of the use of a preliminary injection of atropine and morphine, which in turn may render prolonged nasal "gas" available in cases otherwise calling for ether. Dr. Hilliard's lecture is of more than passing interest, and the views he puts forward deserve careful consideration, though we suspect that some medical practitioners and dental surgeons will find difficulty in agreeing that wholesale extraction at one operation is a good routine procedure.

## YELLOW FEVER IN WEST AFRICA.

WHILE it no longer inspires the old terror, and has been robbed of its strongholds in most parts of the New World, owing to the ease with which the insect vector *Aedes (Stegomyia) argenteus* can be attacked, yellow fever still preserves the secret of its identity, even though, as recorded in our issue of April 28th, some new light has lately been thrown upon the nature of the virus. Moreover, the disease still continues to smoulder on the West Coast of Africa, blazing up from time to time into smaller epidemics which no one can afford to neglect. These have been the subject of communications by various writers, such as Lasnet (French West Africa, 1926-27, *Bull. Acad. Med.*), Aitkin and Smith (Lagos, 1926, *Trans. Roy. Soc. Trop. Med. and Hyg.*), and now the outbreak in Accra (March-June, 1927) is dealt with by Dr. Selwyn-Clarke in a report published by the Gold Coast Government.<sup>2</sup> For the whole colony during the year 1926 there had been 8 European and 57 African cases; during 1927, 14 (10) Europeans, 88 (25) Africans, and 5 (5) Syrians (the numbers in parentheses being the number of fatal cases among them), a bigger outbreak than had ever previously been recorded, leaving out of account the estimated figures given by the Rockefeller Commission for Asamankese (1926). The large number of African cases is worthy of note, and is probably explained by the easier methods of communication on the one hand, and, on the other, the greater facilities for recognizing the disease. For the town of Accra the figures were 3 (3) Europeans, 9 (4) Africans, and 4 (4) Syrians; these are small figures, but the history

of this little outbreak is interesting. The disease was doubtless introduced from one of the several infected areas but a few miles from Accra. The first case was a Syrian, as has happened before along the coast of West Africa. Dr. Selwyn-Clarke then traces the circumstances leading to the infection of subsequent cases, with a short clinical account of each, and the measures adopted to prevent the spread of the epidemic. There was, as is commonly the case, considerable difficulty in making a diagnosis within the first three or four days—that is, during the period when the patient is infective—and the lack of some means of getting over this difficulty was severely felt. Clinically the disease varied somewhat from yellow fever as seen in America, as has been before remarked, and in no case, confirming previous experience in Africa, was the *Leptospira icteroides* discovered. The American commission has, however, using some of these cases as the source of the virus, carried out successful experimental transmission to animals, and all recent work goes to prove that yellow fever is caused by a filterable virus, and that *L. icteroides* is identical with *L. ictero-haemorrhagica*, and plays no part in that disease. Lessons may be learned even from so small a series of facts as are presented in the Accra report. Among these are the necessity for an efficient medical and sanitary service, armed with the needful resources and backed with the essential legal powers to act; the urgent need of some biochemical test as a rapid means of diagnosis at an early stage of the disease; and the danger involved in non-segregation of native populations in townships which include European inhabitants. This last question is one which, of course, not only arises when protective measures against yellow fever are under consideration, but in malaria and other tropical diseases also. It is one which has often not been sufficiently recognized by Europeans, and has led to feelings of antagonism on the part of the natives, but it should never be lost sight of when dealing with towns containing native elements whose standard of hygiene is below the European level.

## LIGHTING AND FINE WORK.

LAST year there was issued a joint report of the Industrial Fatigue Research Board and Illuminating Research Committee on an inquiry into the optimum illumination required for typesetting by hand in the printing industry. The results suggested that with a system of direct lighting output did not reach its maximum, nor errors and turned letters (letters set upside down) their minima, until an artificial illumination of approximately 20 foot-candles was attained—an amount believed to be much higher than that usually found in printing offices to-day. This investigation has now been extended by an inquiry into the kind of artificial lighting<sup>1</sup> that gives the best results as judged by the same tests in this operation, taken as typical of fine work. Illumination was standardized at 10 foot-candles, but the type of lighting varied from direct to semi-indirect and complete indirect, with the intermediate provision of combined direct and semi-indirect. The direct was the common bulb lamp, but in the tests the lamps were fitted into a trough that reflected the light upon the type-case and protected the eyes of the compositor. Semi-indirect lighting was obtained by reflectors of various types above the lamp and opal shields below it. The tests showed the usual diurnal variation in output and errors; output tailed off towards the end of the morning and again in the late afternoon, while errors at first declined and then tended to increase as fatigue came on. There was some evidence that the semi-indirect system gave the best results; output was increased and errors diminished. The mixed system of direct and semi-indirect lighting, though highly

<sup>1</sup> *Lancet*, April 21st, 1928.<sup>2</sup> Report on Yellow Fever in Accra, March-June, 1927. Gold Coast: Government Printing Office, Accra, 1928. 2s.<sup>1</sup> The Effect of Different Systems of Lighting on Output and Accuracy in Fine Work (Typesetting by Hand). London: H.M. Stationery Office, 1928. 4d. net.

approved by the printers, did not seem so favourable to accurate work. Indirect lighting, where the lamp was enclosed within a white enamelled opaque bowl surmounted by a trumpet-shaped pale blue glass intended to give an approximate daylight effect, was much liked by the printers, but was not entirely satisfactory. The main conclusion derived from this report is that good lighting—good by reason both of sufficiency and of wise distribution—is a true economy in furthering the comfort of workers and improving their efficiency. In conclusion, it may be suggested that good lighting in the home, though less susceptible to investigation and less obviously of economic consequence, also deserves the greatest consideration, notably where much sewing or study is done.

#### CHARLES NICOLLE.

THIS year has witnessed the twenty-fifth anniversary of the assumption by Dr. Charles Nicolle of the charge of the Pasteur Institute at Tunis. At the end of last month the event was celebrated by a distinguished company, which met in the municipal theatre of the town. Representatives were present from the Pasteur Institute in Paris and from medical societies at Rouen, Havre, and elsewhere, together with the General Officer commanding the French troops in Tunis, several officers of the navy, the Swedish, Spanish, Italian, and United States Consuls, and His Britannic Majesty's Consul-General in Tunis, Mr. J. M. MacLeod. A congratulatory message was received from Madame Valléry Radot, Pasteur's daughter. Dr. Conseil presented to Dr. Nicolle a beautiful gold medal to express the gratitude of the French people to their admired compatriot. Dr. Nicolle, in replying, spoke of the grey sky of Rouen, and alluded to his Norman ancestry. He modestly touched but lightly on his own fundamental work, but drew attention to the wide and varied usefulness of the Pasteur Institute in Tunis. He referred to its antimalarial research, to the transmission of typhus fever to animals, and to the investigation of trachoma. He recalled the study of Mediterranean fever, the serum prophylaxis of measles, investigations into rabies, and other matters by which the Institute has rendered such signal benefit, not only to North Africa, but to medicine in general. One speaker quoted Flaubert in *Salammbô*: "Tunis is a land of greenery and birds. Under its orange trees the air is so sweet that it is impossible to die." These words, he said, had proved prophetic. The Pasteur Institute of Tunis had realized Gustavo Flaubert's dream, and the author and inspiration of the whole had been Dr. Charles Nicolle. Scientists and medical men in this country will join with their colleagues in France and all over the world in congratulating Dr. Nicolle on this auspicious occasion, which marks a stage in his distinguished service, but happily does not put a period to it.

#### A CORONER'S DISCRETION.

THE office of coroner is an ancient and honourable one. Dr. Whitehouse, coroner for South-East London, is a barrister-at-law and the author of *Notes for Guidance of Coroners' Officers* and of *The Coroner and his Office*. He, in common with all other coroners, is supposed to be at liberty to do and say whatever he likes in his own court, subject only to the jurisdiction of the Lord Chancellor with respect to his removal. Nevertheless, the conduct of an inquest and public pronouncements made by a coroner in his court may still be the subject of public comment and criticism. At an inquest held recently at Greenwich a verdict of "Death from natural causes" was recorded in the case of a man who died suddenly while ascending an omnibus. In the course of the case it appeared that a doctor, at the instance of the London

General Omnibus Company, had been present at the *post-mortem* examination without having previously asked the permission of the coroner. Thereupon Dr. Whitehouse is reported to have said that "if the company does things like that I will shut them out of court entirely," and "I will see that the doctor is never present in my court on any future occasion." It thus appears that the coroner has announced in advance his intention to exclude from his court, either absolutely or in certain contingencies, one or more persons who may quite probably be the most material witnesses in some future cases. Surely if a coroner may admit or exclude such witnesses at his whim and pleasure confidence in the usefulness of inquests cannot fail to be undermined. The medical man concerned in this incident committed the error of not asking the coroner's permission to attend the *post-mortem* examination. No doubt he was at fault; but exemption from the necessity of attending before the coroner in future may, of course, be regarded from the personal aspect as a privilege rather than as a punishment. In view of the remarks of the coroner in this case, too, it may be worth while to point out at any rate one matter which is outside the coroner's discretion. Section 22 (4) of the Coroners (Amendment) Act, 1926, reads: "Where a person states upon oath before the coroner that in his belief the death of the deceased was caused partly or entirely by the improper or negligent treatment of a medical practitioner or other person . . . such medical practitioner or other person shall have the right, if he so desires, to be represented at any *post-mortem* examination."

#### THE NATIONAL DAIRY COUNCIL OF CANADA.

THE report of the proceedings of the National Dairy Council of Canada contains several features of interest from the medical point of view. The first impression, perhaps, is that of surprise at the efforts made by the dairy interests to increase the consumption of milk and dairy products. It is natural for traders to wish to dispose of as much of their merchandise as possible, but to the average person milk is so much a staple of food that it seems hardly worth while to labour the point with advertising. An article will be written, for example, around such a remark as "A bottle of milk and a bath," which was the first request made by Lindbergh after his famous transatlantic flight, and this will be published in the newspapers; or else sets of posters and bulletins showing the energy-producing food value of milk, butter, and ice cream will be sent to teachers and home nurses throughout the country. Such "rules of health" are promulgated as the following: "A bottle of milk is a bottle of health"; "Open the window and throw out your chest"; "Be true to your teeth so that they will not be false to you." Prominent athletes are the keystone of some of the advertisements; just before the prize-fight between Tunney and Dempsey some enterprising person discovered that Tunney drank a quart of milk a day, while Dempsey drank only a glass, and this was widely advertised in the Chicago papers. It is clear, however, that the general run of the National Dairy Council's activities has included more than the mere advertising of dairy products. The importance of sanitary precautions is fully recognized, and one of the immediate results of the convention was the passing of a resolution calling on the Government of Canada to bring in legislation providing for "a single, uniform, and compulsory standard of inspection of all farms producing milk and cream." The need for some such uniformity in methods throughout the country is becoming all the greater in view of the widening of the markets for dairy products. The deplorable incident of the typhoid epidemic in Montreal last spring served to show that one province at least needed an improved system of inspection. Other matters fully

discussed were the pasteurization of milk and the eradication of bovine tuberculosis, and on these points also resolutions were passed calling for legislative action. The greater part of the discussion in this convention was very naturally concerned with the business aspects of dairying, but credit is due to those who conduct this business for displaying a wide and intelligent interest in the sanitary problems arising from the handling of milk and other dairy products. Due prominence was given to the fact that the eighth World's Dairy Congress is to be held in England this July, under the patronage of the King, who has invited all the delegates to visit Windsor and see his dairy and herds, in which it is known he takes so keen an interest.

#### PARTIAL DEATH.

In the course of one of the addresses at the staff meetings of the Mayo Clinic, Dr. E. Libman spoke on the subject of invasion of the body during life by the *Bacillus aerogenes capsulatus*, especially after operations, when it may imitate lung complications, such as embolism and bronchopneumonia, and may cause unexplained post-operative deaths. The clinical picture in these cases is "moderate fever, signs in the lung resembling broncho-pneumonia, and then a sudden sharp ending with pulmonary oedema and very high temperature. If a patient has a cadaveric look or emits a cadaveric odour, or if the peculiar blue discolorations of the skin are present, there is more reason to suspect the presence of this condition." Dr. Libman answers his own inquiry, "What is the meaning of this general invasion?" by suggesting that the patient may be regarded as partly dead, which would account for the cadaveric appearance and odour, and the multiplication of bacteria which does not occur under ordinary conditions. This question of partial death, which had interested him for years, he found to be no new idea, for Michel Peter, in his lectures on heart disease (*Leçons de clinique médicale*, 1870, ii, 791) dealt with "mort partielle," and a century earlier Bichat, in his monograph *Recherches physiologiques sur la vie et la mort*, discussed the problem with particular reference to the brain, lungs, and heart, and the influence of death of one organ on the others—a subject in these days familiar enough in connexion with gangrene of the extremities. Dr. Libman quotes in conclusion Peter's expressive dictum, "One lives until one stops dying."

#### THE ACADEMY OF MEDICINE OF JERUSALEM.

PROBABLY the most completely international and polyglot medical association in the world exists to-day in Jerusalem, where at least ten mother tongues are spoken by the forty-five members of the Academy of Medicine, and where there are almost as many different training schools and modes of thought as there are members. It may be recalled that we gave a short account of the progress of the medical department of the Hebrew University on March 7th, 1925 (p. 471). It is not surprising that the foundation of such a society, even with its very laudable objects of promoting good feeling amongst medical practitioners and the encouragement of scientific research, encountered many obstacles. Indeed, a first attempt failed on account of the language difficulty, but this has been overcome, and the first issue of the annual *Bulletin*, edited by Dr. H. J. Orr-Ewing, indicates that the association promises to be a flourishing concern which should go far to solve some of the problems of medical practice in Palestine. Some of the health questions which have to be faced in that country can be better approached if there are full facilities for discussion between medical men, and the *Bulletin*, by printing papers in full or by reporting such discussions, will greatly help

those who are unable to attend. A paper on blindness in Palestine by Dr. A. Tricho in the present issue illustrates this point. It is estimated that there are twenty times as many blind there as in Great Britain in proportion to the population, despite the fact that ophthalmia neonatorum is unknown. Of a large group of binocular blind patients, 72 per cent. were found to have external disease of the conjunctiva as the origin of their disability. Trachoma is the cause of many cases, and acute inflammation supervening on this is very frequent. Glaucoma and cataract come next, with 7.83 and 6.85 per cent. case incidence respectively. Tuberculosis is not uncommon, but syphilitic affections of the eye are comparatively rare, despite the fact that the natives are widely infected with the spirochaete. The vast majority of the blind in Palestine are Arabs, and Dr. Tricho insists that better general hygiene, with expert and timely treatment, will prevent blindness in 75 per cent. of cases. The *Bulletin* also contains an account of the very successful second annual dinner, held on June 23rd, 1927, with Dr. V. Kalbian, president of the academy, in the chair. Dr. Emmanuel Kant, president of the older Jewish Medical Society, was a guest on this occasion, and it is clear that the relations between the academy and the larger Jewish society are of the happiest.

#### METHODS OF SLAUGHTERING.

DR. GERALD LEIGHTON of the Scottish Board of Health, in his Benjamin Ward Richardson Memorial Lecture (now published in pamphlet form), has given an excellent summary of the present position of the meat food industry from a public health point of view. On the advantages of the modern abattoir under the direct control of a public health authority over the privately owned slaughterhouse no doubt can exist. The high standard of proficiency demanded of inspectors is good for both the public and the trade. The former can rest assured of obtaining meat in a wholesome and fresh condition, while the latter can be confident that no carcasses are unjustly condemned. Dr. Leighton is not satisfied with the methods of slaughter of pigs, calves, and sheep. He thinks that no animal should be killed by bleeding without previous stunning. Much improvement in droving and sea transport can yet be made. Rough treatment of animals prior to entering the abattoirs causes much unnecessary suffering. Dr. Leighton's view that animals are indifferent to scenes of bloodshed within slaughterhouses must be listened to with respect, though it leaves us only partially convinced. He advocates the large central abattoir built on the open hall system as opposed to one divided into a number of small booths. The central open abattoir is best for the disposal of offal, and also offers greater facilities for pathological examination.

WE are informed that the Rockefeller Foundation has made an offer to the Government of India of the sum of £100,000 to build and equip an All-India School of Hygiene, opposite the Calcutta School of Tropical Medicine, on condition that the Government of India becomes responsible for the staff, and that the Indian Research Fund Association, which controls the medical research work in India, becomes the governing body. This will allow the present hygiene section of the Calcutta School of Tropical Medicine to be used for the much-needed expansion of that institution.

A MEMORIAL tablet to the late Sir William Leishman, K.C.B., F.R.S., who died on June 2nd, 1926, will be holding the office of Director-General A.M.S., will be unveiled in the Queen Alexandra Military Hospital Chapel, Millbank, S.W., on Saturday, June 2nd, at 11.30 a.m.

# The Harvey Tercentenary.

## RECEPTION OF DELEGATES BY THE KING.

On Monday, May 14th, delegates from universities and medical societies throughout the world met in London to attend the celebrations arranged by the Royal College of Physicians of London in honour of the three hundredth anniversary of the publication of William Harvey's great work, the *De Motu Cordis*. The first event on the programme was the reception of delegates at 11 a.m. by the King at Buckingham Palace. The delegates, numbering nearly 100, were presented to His Majesty by Sir John Rose Bradford, K.C.M.G., F.R.S., President of the College, who delivered an address in the following terms.

### ADDRESS TO HIS MAJESTY.

*May it please your Majesty:*

By Your Majesty's gracious invitation we are gathered here to-day to celebrate the Three Hundredth Anniversary of the first publication of William Harvey's famous book, the so-called *De Motu Cordis*, in which he announced to the whole world the discovery already made known by him to his own medical colleagues in his lectures before the Royal College of Physicians. This book Harvey dedicated to His Majesty King Charles the First.

Harvey's demonstration that the same blood must flow unceasingly round and round the body, visiting its remotest parts, swept away the visionary speculations of his predecessors and paved the way for a scientific explanation of the purpose of the Circulation of the Blood. Thus it is the publication of the *De Motu Cordis* has been rightly acclaimed as the Birthday of Physiology and of Scientific Medicine.

Science knows no boundaries of race or nation, and obedient to this doctrine Representatives of Medical Science from many lands have joined with Representatives of the Universities and Scientific Societies of this Kingdom and of the Dominions of your Empire Overseas to pay homage to the memory of this great English Man of Science.

Your Majesty, in identifying yourself with this Commemoration of Harvey's work, is but treading in the footsteps of your Royal Ancestors. King James the First and King Charles the First both set a true value on Harvey and made him their own Physician, and the latter supplied him with the bodies of deer from the royal herds for his anatomical studies. Harvey constantly brought to King Charles natural curiosities for his inspection, and exhibited to him much of his experimental work. Together also they shared the rare experience of watching the beating heart in a human subject through a defect in the chest-wall produced by disease.

In the Civil War, too, Harvey stood by his Royal Master and was present at Edgehill, in charge of the young Princes Charles and James, and afterwards at Oxford, where by Royal Mandate Harvey was appointed Warden of Merton College.

As President of the Royal College of Physicians of London, on whose roll of Fellows Harvey stands out as its brightest ornament, I have the honour to express to Your Majesty the dutiful thanks of every member of this Delegation for the honour of this Reception, by which Your Majesty to-day participates in the Celebration for which we are all assembled in the Capital of Your Empire.

### THE KING'S REPLY.

I thank you sincerely for your Address. It is a great pleasure to me to join with my people in welcoming the many distinguished men from my Overseas Dominions, and indeed from all parts of the civilized world, now assembled in London in honour of the Tercentenary of Harvey's immortal discovery.

I appreciate the comparison drawn in your Address between my part in to-day's ceremony and the action of my

predecessors, who befriended Harvey in his lifetime. I am proud to think that the Kings of England of that day, recognizing Harvey's great gifts, granted their patronage and help in his work, and are thus entitled to the credit of having contributed to the new birth of medical science.

The importance and value of William Harvey's work cannot be exaggerated. In an age when physiological knowledge was in a state of darkness and chaos, he laid the essential foundation for a science of physiology by demonstrating not only the fact of the circulation of the blood, but the manner in which it took place. He discerned and taught that the true method of scientific progress is by observation and experiment, and it is for this, and not merely as the author of a single discovery, however brilliant and fundamental, that we to-day do honour to the name of Harvey.

Science, as you truly say, knows no boundary of race or nation. Harvey's own career is an instance of this. He was a graduate not only of our own Cambridge, but also of Padua, which ancient and illustrious University I am happy to see represented here to-day. His great book was published in Latin, the universal language of learning, and won acceptance for itself and fame for its author throughout Europe. But, though science is international, each country's contribution may still bear the marks of the national character. And here we may proudly note that Harvey, in his threefold capacity as a successful physician in private practice, as physician to St. Bartholomew's Hospital, and as an eminent student and investigator, foreshadowed what is now, and has long been, characteristic of British physiology—the combination of research with medical and surgical practice, allied with a generous devotion to the service of the poor in the public hospitals.

## RECEPTION AT THE ROYAL COLLEGE OF PHYSICIANS.

### ADMISSION OF HONORARY FELLOWS.

The Library of the Royal College of Physicians, with several portraits of Harvey looking down from its walls, presented a brilliant spectacle on the afternoon of May 14th, when the President (Sir John Rose Bradford) received the delegates and distinguished guests in connexion with the Harvey Tercentenary. The occasion was made the more noteworthy by the admission to Honorary Fellowship of the College of the Earl of Balfour, O.M., Sir Ernest Rutherford, O.M., President of the Royal Society, Professor I. P. Pavlov of the Academy of Sciences, Leningrad, and Professor K. F. Wenckebach of the Academy of Sciences, Vienna. Three eulogies of Harvey were pronounced, the first by an English physiologist, Sir Charles Sherrington, O.M., the second by a French physician, Professor A. Chauffard, and the third by a German anatomist, Professor Keibel.

Academic dress was worn, and the gowns and hoods of some fifty British and foreign universities made a striking picture. Seventeen European countries were represented in the assemblage; there were six delegates from the United States, six from British Dominions beyond the seas, every university in Great Britain and Ireland had its delegate, the Royal College of Surgeons of England and the Royal Colleges of Physicians and Surgeons of Edinburgh and of Dublin were all represented by their Presidents, and in addition there were delegates from the principal medical and scientific societies, the medical services of the Navy, Army, and Air Force, the Indian Medical Service, the British Association, the British Medical Association (represented by Sir Robert Philip, its President), the Medical Research Council, and other bodies. Harvey's birthplace at Folkestone, his school (King's School, Canterbury), his

hospital (St. Bartholomew's), his collegio (Gonville and Caius, Cambridge), as well as Merton College, Oxford, where he was warden, had their delegates.

The President, with the insignia of the College before him, the mace in silver gilt, the caduceus or silver wand, and the Book of Statutes on its velvet cushion, was accompanied by the Censors, and supported by more than one hundred Fellows of the College.

The delegates were received with stately ceremony. Each was introduced to the President, with whom he shook hands, and received from one of the Censors (Sir Farquhar Buzzard) a beautifully printed and bound copy in facsimile of the *De Motu Cordis*, 250 copies of which had been specially produced by a firm of Florentine printers. Many of the delegates presented addresses from the universities or academies they represented. The Universities of Buenos Ayres, of Helsingfors, and of Athens were represented respectively by the Ambassador of the Argentine Republic and the Ministers Plenipotentiary of Finland and of Greece. The Greek Minister presented an illuminated address on vellum in ancient Greek testifying to the rejoicing of the University of Athens in the celebration.

After the presentations of the delegates, which occupied nearly half an hour, the President said that they had assembled to honour the memory of Harvey, and not only to honour the man himself, but to pay a tribute of respect to the method of inquiry which he had instituted. The College was proud to welcome the large number of delegates representing universities, academies, and learned institutions all over the world. In addition, there were a number of other distinguished guests present, a list of whose names he read, who, though not official delegates, had done noteworthy work in medicine, more especially after the method of Harvey. Their names were as follows:

Dr. Clerc, Dr. G. E. Coghill, Professor G. Fano, Professor O. Frank, Professor H. Fredericq, Dr. Gallavardin, Professor L. G. Henderson, Dr. C. H. Best, Professor Noyons, Professor R. Höber, Dr. N. G. Horner, Professor H. Horst-Meyer, Sir Arthur Keith, Dr. Lemierre, Professor G. Liljestrand, Professor O. Loewi, Dr. W. S. Thayer, Professor T. L. Thunberg, and Professor A. V. Hill.

Continuing, the President said that although the College of Physicians had existed for over 400 years it was not clear that it had ever had a roll of Honorary Fellows. It was true that in the time of Harvey, and on Harvey's initiative, the Fellowship was conferred on one man who was not a practitioner of medicine—namely, the Marquis of Dorchester, who was admitted a Fellow in 1658. It was true also that a distant President did admit a number of individuals, all of them practitioners of medicine, who were styled in the records Honorary Fellows, but they were not honorary in the sense in which that term would now be used. His late Majesty Edward VII also, when Prince of Wales, agreed to accept the Fellowship at the hands

of Sir Samuel Wilks, who was then President. But with these possible exceptions the College, ancient as it was, had not instituted an Honorary Fellowship. It was thought, however, not inappropriate to the present occasion, when they were assembled to honour the memory of the greatest Fellow the College ever had, to institute such a distinction, the Honorary Fellowship to be conferred upon those who had rendered signal service to medicine either directly or indirectly.

It was possible to serve medicine in more ways than one. The College was right in honouring men who had served medicine without taking any active part in its practice or in the prosecution of research in ancillary sciences. There were a number of laymen, both in history and in the present, who had shown an intimate acquaintance and

sympathy with the aims and objects of medicine, and the College felt that it was appropriate on this occasion to honour one such in the person of the Earl of Balfour. (Applause.) It was a matter of regret that Lord Balfour was not well enough to be present on the occasion; a message had been received from him to say how greatly he appreciated what was proposed and how much he regretted his enforced absence. It was interesting at this moment, when it was proposed to honour a layman, that another distinguished man, who was also to be made an Honorary Fellow, Professor Pavlov, had stated recently that he received his inspiration for his work on physiology from reading the works of another layman, George Henry Lewes, who, like Lord Balfour, was a philosopher.

A second category of men who had served the cause of medicine were those who had

devoted their energies to the prosecution of natural science. The relationship of science to medicine was close and reciprocal. In the Fellowship of the College in the past there had been men whose most notable claim to distinction was not their work in medicine, but in science. It was now proposed to confer the Honorary Fellowship on Sir Ernest Rutherford, the President of the Royal Society, whose devoted researches in science made him a worthy recipient of the honour. The other proposed recipients, Professor Pavlov of the Academy of Sciences, Leningrad, the very distinguished physiologist, and Dr. K. F. Wenckebach of the Academy of Sciences, Vienna, the equally distinguished cardiologist, might be taken as representing the two sides of medicine—the one essentially scientific, the other, while also scientific, more directly connected with the art they all practised.

The three recipients of the honour who were present then came forward and signed the register. Addressing Sir Ernest Rutherford, the President admitted him in these terms: "I, John Rose Bradford, President of the Royal College of Physicians of London, admit you, Ernest Rutherford, to our Honorary Fellowship. I wish you every happiness." The same form was used in the case of Professor Pavlov and Dr. Wenckebach. All three were received with prolonged applause.

William Harvey, 1578 1657 From the portrait by Cornelius Jansen belonging to the Royal College of Physicians of London.

## EULOGIES OF HARVEY.

The remaining business was the pronouncement of three eulogies on Harvey by Sir Charles Sherrington, Professor A. Chauffard of Paris, and Professor Franz Keibel of Berlin, after which the President briefly expressed the thanks of the gathering to the three speakers, and the proceedings terminated.

SIR CHARLES SHERRINGTON said that in William Harvey they bore in remembrance one who was Fellow, Censor, Treasurer, and, for a day, President-Elect of the College, its benefactor by gift and bequest, and part and parcel of its pride and honour. Three and a half centuries had passed since his birth, and three since his unforgettable book. In science as in letters, the book is of the man. Harvey's book embodied not only Harvey's thought, but what his hand had contrived, searched for, and found: At the Renaissance the spirit of man turned from an old order, "cabined within a rounded scheme of things," to move and inhabit for itself afresh. The new day broke first on scholarship and letters; in science it adventured first among the stars. When it turned to explore the inward meaning of organ and organism, the living function, the Renaissance was William Harvey.

Harvey was the pupil and fervent admirer of the masters of antiquity. To him, listening in the steep theatre at Padua to Fabricius expounding in Latin the parts displayed below on the anatomy table, Aristotle and Galen in living authority were as present as was Fabricius himself. But his famous exhortation to others—to search out Nature by experiment—he addressed early to himself. For his great discovery he applied only those means and appliances which had been at men's disposal from classical antiquity onwards. His was the triumph of the new spirit aided only by its own freedom. He was the coming of modernity; not that he was entirely modern, for he let ten years pass between his discovery and sending to the press the slender book which engendered modern medicine. The message had to fight its way, and in some quarters did so slowly. But Harvey relied on the truth and the future. He could hardly have guessed the long train of gifted men who were to extend his work—Einhoven and Starling, so freshly lost to us, and, of his own College to-day, Dale and Lewis, brilliantly extending by discovery his original discovery.

To supply in forty-nine small pages a refutation of nineteen centuries' tradition of continuous error argued a fine restraint. But once at least Harvey gave his spirit rein, and in forecasting the uses which must accrue to the blood in virtue of its circulating, burst forth into a luxuriant passage. This was a new Harvey, a Harvey fired with constructive imagination, a Harvey who could write in red ink on the cover of his notebook, "Everything is full of Jove!" One of the deep springs of his enthusiasm was his philosophy of nature.

Sir Charles Sherrington concluded: "The work of Harvey, the spirit of it no less than the import of it, provides his eulogy and makes superfluous all other. His great discovery, aside from its intellectual worth, secured an item of knowledge than which no other single item has so served to grow, as from a seed, medicine as we now know it. And it was the reassertion, the rebirth, of the method of experiment which, wedded to observation, had created the medicine—and the surgery—of the civilized world to-day. To engender medicine anew is to engender a whole world of correlated knowledge; and an attendant world of beneficence no less. The circulation of the blood, the meaning of the heart, the light of a victorious method! May we not affirm that modern medicine does in fact start there? Harvey, founder of modern medicine! He would himself have felt no term can carry richer or lovelier praise from a grateful world."

Professor CHAUFFARD said how greatly he appreciated the invitation to speak at this commemoration. The honour embraced the Academy of Medicine of Paris, of which he was a delegate. To speak of Harvey and his book was a real joy to a physician. In the first place, he was greatly impressed by the courage exemplified in its publication.

Only a voice here and there, such as that of Vesalius and Servetus, in the sixteenth century had disputed, with great temerity, the authority of Galen. Harvey himself lost part of his practice, and had many opponents, less in his own country than in Italy and Germany, but most of all in France. If his discovery was a work of courage it was also a work of patience. The speaker reminded his audience that in 1616, twelve years before the publication of his book, Harvey, to an audience of about forty persons at the College of Physicians, made a public statement of his ideas regarding the circulation of the blood. The publication was preceded by many years of silence—a period of incubation and verification necessary to all great work. There was a similar period of quiet in the history of Francis Bacon before he gave to the world his *Novum Organum*, and the same was true of Newton, and Pasteur, and Darwin, and others. Genius had long patience. The wise man avoided the error of premature publication.

Another most striking characteristic of Harvey's work was his industry. It was through a variety of direct observations on many different creatures that he gradually overcame the difficulty of his subject and arrived at his explanation of the functions and structure of the heart. But he had also the vision to see far ahead how many problems could be solved, how much advance made possible as a result of this new conception. Harvey was fully conscious of the immense future scope of his discovery. As time had gone on, the truth of it had been preserved; it had been supplemented by the modern means of observation available, but not diminished, only completed and multiplied in value. His work stood intact. In other respects also, in the general precepts which he laid down for the teaching of anatomy, for example, not one word needed to be taken away. In embryology he showed the same grasp of his subject and the same striking modernity of ideas. And Harvey himself was in no way inferior to his work. He was a man of the highest moral character, true to his convictions and friendships, devoted to the interest of the College, of which he was a most generous benefactor. It was fitting that on this occasion the whole world of medicine should unite in eulogy and in pious gratitude.

The final eulogy, by Professor FRANZ KEIBEL, was delivered in German. We are indebted to Dr. J. D. Rolleston for the following translation:

It is my privilege to say a few words on the relation of William Harvey to anatomy. First of all, let me briefly allude to the relation of physiology to anatomy. Both sciences have a common root and are thereby closely associated, but even in their terminal ramifications to-day they are not completely separated from one another. I need only remind you that the wide subject of joint physiology has received most attention from anatomists. The same was true, even in a greater degree, in the time of William Harvey, and we know that Harvey was not only a great experimental physiologist, but also an outstanding anatomist. Of anatomy he said that it should not be learnt from books, but from dissections; not from philosophical dogmas, but from the structure of the body.

Harvey, of course, like all great discoverers, had his predecessors as well as his followers, who brought his work to completion. It is a remarkable fact that Andreas Vesalius, the great reformer of human anatomy, can only in a very restricted sense be included among them, in spite of his excellent description of the heart. Vesalius could not find any pores in the ventricular septum, but, nevertheless, supposed that air passed through it, on this point being in agreement with his great opponent Galen.

Among Harvey's predecessors must be mentioned the unfortunate Servetus, who gave a correct description of the lesser circulation in a theological book entitled *Christianismi Restitutio* (1553). This work was burnt with its author, but it has recently been suggested that it was known to Realdus Columbus, who gave a similar description of the lesser circulation, although he made no actual mention of the work of Servetus. The other predecessors were Caelius, Cannani, and Fabricius ab Aquapendente, Harvey's teacher at Padua. Cannani discovered the valves of the veins, of which Fabricius published admirable drawings. Fallopius also should not be forgotten.

All these men had in their hands the key to the great riddle of which Harvey said at the commencement of his studies with Fracastor that it was so difficult that God alone knew the answer. They were in possession of a number of isolated facts, by proper application of which to inductive conclusions they might have solved the riddle of the function of the heart; but they did not draw these conclusions, and therefore to William Harvey belongs the full glory of having discovered the circulation of the blood and the function of the heart.

Among those who completed Harvey's work should be mentioned Marcello Malpighi, who discovered the capillaries, and Aselli, Pecquet, and Rudheek, who discovered the lacteals and receptaculum chyli. It is true that Harvey used the word "capillaries," but applied it only to the finest terminations of the arteries. He convincingly proved the connexion of the arteries with the veins, but did not succeed in demonstrating it, the demonstration of this connexion being left to Malpighi in the lungs and urinary bladder of the frog. The discovery of the lacteals and receptaculum chyli may be regarded as important additions to the doctrine of the circulation of the blood. Malpighi's discovery was made in the year 1661, four years after Harvey's death in 1657. In 1665 Malpighi discovered the blood corpuscles.

Some time elapsed before the doctrine of the circulation was generally accepted, so firmly rooted were Galen's errors and so great was the reputation of this ancient physician, who for centuries was worshipped as a saint. New problems, of course, arose, and additions to knowledge were made. I need only allude to the auriculo-ventricular bundle—whose discovery by William His, junr., almost all of us can remember—a bundle which gave us such important information about the functions of the heart. We also must not forget that Harvey took a keen interest in the comparative study of organisms, and is therefore to be regarded as one of the founders of comparative anatomy. Moreover, the latest investigations on the heart and circulation rest on the foundation which Harvey laid in so masterly a manner, and this foundation will last as long as our science survives.

#### THE GROCERS COMPANY.

Among the principal events of this Harvey Tercentenary week has been the banquet given by the Worshipful Company of Grocers in its magnificent Hall in the City of London on Monday evening. A very large and distinguished company of official delegates and other guests were received by the Master, Lieut.-Colonel Francis W. Heath, C.M.G., and the Wardens, and were sumptuously entertained in the manner for which the great City Companies are famous the world over. The speeches, and the music also, were worthy of the occasion. In proposing the health

of the delegates Lord Hanworth, Master of the Rolls, showed himself fully acquainted with the life and work of William Harvey, and recalled that Harvey himself may have dined on that site as the guest of his brother, who was a member of the Grocers Company. Eloquent replies in fluent English were made by Professor J. van der Hoeve (of the Royal Academy of Sciences, Amsterdam) and Professor G. H. Monrad-Krohn (of the University of Oslo). The toast of "The Company of Grocers" was very appropriately in the hands of Sir John Rose Bradford, President of the Royal College of Physicians of London, who has had long associations with the Company, and whose name, with that of Sir James Paget, appears on the roll of its Honorary Freemen. In the course of his speech Sir John made

acknowledgement of the splendid hospitality of the Grocers Company on this memorable occasion, and indicated something of the debt owed by medicine to that ancient City Guild. Many of our readers are well aware that in mediaeval times the Apothecaries were linked with the Grocers, and so remained until their separate incorporation as a Company in the reign of James I. The Grocers Company has always given, and continues to give, generous aid to hospitals and other charitable agencies, but more than any other Guild it has recognized that in the advancement of education and of scientific discovery lies the best hope of diminishing poverty and suffering, and of promoting national health and prosperity. It has given practical effect to these views by the establishment of schools (notably Oundle), the provision of scholarships at the universities, and the endowment of scientific research. With the object of encouraging original research in preventive medicine the Company awards scholarships to assist

the investigation of matters connected with the causation of disease or the means of preventing premature death. Discoveries of much value have resulted from the work of Grocers' research scholars, and not a few of those who have earned distinction in that branch of science, such as Woolridge, Sims Woodhead, MacFadyen, Rose Bradford, Starling, and Bulloch, have been helped on their way by the Company's endowments. Moreover, when the scheme for founding in this country a School of Preventive Medicine was delayed in execution by want of funds the Grocers Company, by timely financial help, relieved the promoters from their difficulties, and did much to aid the establishment of the foundation now known as the Lister Institute, which has greatly enlarged our knowledge of the causes of disease. It is fitting that these services, briefly alluded to on Monday by the President of the Royal College of Physicians, should be called to mind at a moment when the Company has given further proof of its friendly feeling towards the medical profession and of its belief in medical research.

Title-page of first edition of Harvey's *De Motu Cordis*, published at Frankfurt, 1628.

## THE HARVEY FILM.

The demonstrations arranged by the Royal College of Physicians in the Physiological Department at University College (of which preliminary particulars were given in our last issue at p. 819) included a reproduction of Harvey's original experiments displayed by cinematograph. Something of the thrill which Harvey must have felt as he slowly and cautiously traced the steps which led to his epoch-making discovery was conveyed to those who, three centuries later, have watched the graphic unfolding of the argument by the art of the film.

The familiar portrait by Cornelius Jansen of Harvey sitting at a table is first shown, and then the fingers slowly seem to come to life. They are next seen represented on an enlarged scale. First they turn the pages of Galen with a hesitancy which suggests doubt; then the effect of the disturbing observations of Vesalius, Servetus, Fabricius, and Columbus is indicated. Thinking gives place to testing; the books are closed, and the body is opened that its secret may be revealed. The hands pass from one animal to another as the various stages in the argument are built up. The rapid beating of the hearts of dogs and cats loses its mystery when the hearts of snakes and eels are exposed. Questions arise and are answered. What is the function of this contracting organ? Where does the blood go? Where are these alleged pores of Vesalius to be found in the curiously tough ventricular septum? Where does the blood come from in order to reach the heart, and what evidence is there of the existence of the "natural" and "vital" spirits postulated by Galen? Then the famous time calculation is indicated, and the discovery that in one hour the heart expels from itself a greater quantity of blood than the body holds. So, irresistibly, the invisible reasoning which guided the testing fingers is driven to the idea that there may be motion in a circle. Then in quick stages comes the revelation of the functions of the valves in the veins and heart, and with the experimenting fingers now applied to the human body the great conclusion is inevitable. The last part of the film represents Harvey turning the pages of his immortal work, *Exercitatio Anatomica de Motu Cordis et Sanguinis*; his hands close the book and lay it on one side. The fingers become still; the hands are again those of Harvey in the portrait, sitting at the table.

This cinematograph film was more than dramatic; it was an education in itself, and a quiet rebuke to guesswork without experimentation. To Sir Thomas Lewis and Dr. H. H. Dale a very high meed of congratulation is due for a brilliant conception and for a perfect demonstration of how a great genius reached his greatest discovery. This film might well be shown to every medical student; it tells more clearly than spoken words how knowledge grows from more to more, and how alone error can be replaced by truth.

## EXHIBITION AT THE COLLEGE OF PHYSICIANS.

On the afternoon of Tuesday, May 15th, delegates and guests and the ladies accompanying them were entertained to tea at the Royal College of Physicians. They were received at the entrance to the Library by the President, and an interesting account of the College and its treasures was given by the Harveian Librarian, Dr. Arnold Chaplin, who briefly traced the history of the corporation from its foundation by Thomas Linacre in 1518, and described the vicissitudes of the Library and the College houses. Books, manuscripts, pictures, silver, and other objects of interest, some of them relating to Harvey, were displayed. The portrait of him painted by Cornelius Jansen, which hangs behind the President's chair, is reproduced at p. 867 in our present issue. Other exhibits in the Large Library included the original Charter of the College, granted by Henry VIII in 1518, the first Book of Statutes, the first Book of the Annals of the College in the handwriting of Dr. John Cains, the Signature Book of the Fellows, dating from 1647, and Sydenham's Notebook, written with his own hand. There were also on view the first book printed in English by Caxton in 1474, and other incunabula, including the first printed edition of Homer, many early and rare editions and manuscripts, and three books saved from the

Great Fire of 1666. On a separate table were laid out many of the earlier editions of Harvey's work, *De Motu Cordis*, including the first edition published at Frankfurt in 1628, whose title-page we reproduce at p. 869; also eleven autograph letters of Harvey, a book with marginal notes in his hand, the obony pointer used by him when delivering his Lumleian Lectures, and his Diploma of Doctor of Medicine in the University of Padua. In the Censors' Room were displayed the silver plate belonging to the College, the ceremonial mace, the silver caduceus designed by Caius, and the famous gold-headed cane, whose imaginary adventures were told by MacMichael. Another object of particular interest was the catalogue of the library of the Marquess of Dorchester, who, after the destruction of all but 140 of the College's 1,300 volumes in the Great Fire of London, bequeathed to it the whole of his books, amounting to some 4,000 volumes and comprising one of the finest libraries of the time in England.

## HARVEY AND ST. BARTHOLOMEW'S HOSPITAL.

Harvey's connexion with St. Bartholomew's Hospital was commemorated by a luncheon in the Great Hall on May 15th, when Lord Stanmore, treasurer of the Hospital, presided. Sir WILMOT HERRINGHAM delivered an address, which was subsequently described by the President of the Royal College of Physicians as one of the outstanding features of the centenary celebrations. After paying tribute to the valuable historical research of his colleague Sir D'Arcy Power, Sir Wilmot Herringham recalled how Harvey, after taking an Arts course at Cambridge, studied at Padua for four years and obtained his doctorate there; he then returned to Cambridge and proceeded M.D., and before the age of 27 came to live close to the Hospital in the parish of St. Martin, Ludgate Hill. A year or two later he was elected "physician in reversion" to the Hospital, corresponding to the post of assistant physician to-day; in October, 1609, he was promoted full physician. Sir Wilmot read out the words of the charge given to Harvey on his appointment, with its reference to the care of the poor and the collecting together of patients so often as might be required for the investigation of their afflictions. He added that no record of Harvey's work at the Hospital for the next twenty years was extant, though during that period he was elected Lumleian lecturer at the Royal College of Physicians, and also physician to James I. The next apparent reference to him in the records of St. Bartholomew's was his obtaining leave of absence to be with the Duke of Lennox on his travels abroad. Harvey accompanied Charles I on his journey to Edinburgh for his coronation, and, while the king was wrestling in argument with the divines, the physician went off to study the birds at the Bass rock. At a later date he appeared as a reformer at St. Bartholomew's Hospital, introducing new rules and improvements. He suggested that no patients should be admitted if they were suffering from trivial or incurable complaints. He advised that cases of venereal disease should be treated in a building separated entirely from the Hospital. No patients were to stay in the institution for more than a certain time without special leave, while the disobedient and those who refused to take their medicine were to be discharged. The surgeons were not to allow their work to be done by their "boys," nor to admit patients without preliminary examination. The surgeons should be restrained under the control of the physicians, and should perform no operation without their counsel and advice. Sir Wilmot explained that the suggested enactment implied, therefore, that operative treatment should be directed by the most skilled knowledge at that time. Harvey himself in his Lumleian lectures covered the whole of medicine and surgery as it was then understood, and was an operator himself. In 1636 he went abroad again, this time with Lord Arundel in the vain attempt to regain the Palatinate for the nephew of Charles I. He was commissioned to buy pictures at Venice for the king, who was one of the leading art collectors of the period. In 1637 he returned to England, and two years later was appointed physician to the king, with quarters in Whitehall, an allowance from the kitchen, and a yearly stipend of £400. He joined the king in the

Civil War, and consequently, in 1643, the House of Commons ordered him to be expelled from St. Bartholomew's Hospital, thus terminating his connexion with this institution. Sir Wilmot Herringham next emphasized points of interest in the character of Harvey, whose will illustrated his liberal and warm-hearted nature. No member of his family escaped mention in it in the most cordial terms, and all were given bequests. Harvey was generous, both in public and private life; he was deeply beloved by his friends, and a great favourite with Charles I and Lord Arundel, two of the most cultured men in Europe at that time. He was an intimate friend of the learned and famous judge John Selden, with whom he conspired on one occasion to cure a man who insisted that he was possessed by two devils, which instructed him to destroy Selden. A parchment was given to the patient, curiously inscribed and sealed, and three months later the patient returned with the information that the two devils had been successfully driven out, but that two others had arrived making the same demands as regards murder. Selden and Harvey prepared another parchment, and it was explained to the patient that, should there be a recurrence, the only two men in the world who could save the sufferer were the two conspirators, who thus ingeniously insured their lives. Harvey attended professionally Francis Bacon, of whom he said, rather unkindly, that he talked philosophy like a Lord Chancellor. Sir Wilmot remarked that Harvey might well be described as the first "scientific" man in the modern sense of the word; he observed carefully, made experiments, and drew conclusions. He would have been at home in a modern physiological or scientific laboratory as no other man of his time could have been; Gilbert was his only possible rival in this respect. Harvey might not have been so deep in his reasoning as his successor John Hunter, but he was at any rate the founder of the English school of physiology. For many years he was passed over for the presidency of the Royal College of Physicians, at first by reason of the seniority of others, but later, in 1641, he was deliberately ignored, owing, it is supposed, to political feeling, which was then running high in opposition to the king and those around him. When the offer was eventually made to Harvey, at the age of 76, he was too old to accept it. His house had been destroyed in the Civil War and his papers were scattered; yet his closing years were tranquil, and he passed them happily among his books in the family circle.

## TETRA-ETHYL LEAD IN MOTOR SPIRIT.

### COMMITTEE OF INQUIRY.

At the second public meeting\* of the committee of inquiry on lead ethyl petrol, held on May 15th under the chairmanship of Sir FREDERICK WILLIS, evidence was given by Dr. MYN COPLANS. The witness submitted a précis of his evidence, which, however, was not circulated to the press. He was questioned by the chairman and other members on the results of his investigations as published in the *Daily Mail*, and in particular as to his medical examination of two men who had "serviced" cars using ethyl petrol, one of whom was found to be excreting a small amount of lead. Lead was also found on the overalls of these mechanics.

Dr. Coplans, in reply to Sir Frederick Willis, said that in his investigations on the excreta of these men spectroscopic examination, which within limits was a quantitative as well as a qualitative test, was employed. With regard to the overalls, he suggested that it was dangerous to send such articles to the laundry without some special notification. In his précis he had referred to the possibility of contamination of water supplies; he had in mind particularly the shallow wells used in the country for drinking purposes. Sir F. Willis asked whether, as a scientific man, he thought that the amount of work he personally had done justified his rather alarmist statements, to which he replied that his work was borne out by more prolonged investigations in the United States, where a number of authorities considered that the unlimited use of ethyl petrol constituted a public danger. He did not think that he had exaggerated the dangers of exhaust gases in confined spaces. He agreed that he had imputed that the use of ethyl petrol for motor cars in this country might be followed by dire results, but, of course, such results depended upon the number of cars, the congestion, and the susceptibility of the

persons concerned. Sir F. Willis said that if the *Daily Mail* had been really anxious to get to the bottom of this problem in a scientific way one would have thought that some of this American work which told in the opposite direction would have been mentioned. The United States Government committee, set up on the recommendation of the conference called by the Surgeon-General, had been unable to find any definite cases of lead poisoning, and held that at present there was no good ground for prohibiting the use of "ethyl gasoline of the composition specified as a motor fuel, provided its distribution and use are controlled by definite regulations." Dr. Coplans said that whatever might have been the case with the *Daily Mail*, he himself had referred in his articles in the medical journals to this American report. He agreed, in further reply, that he had not controlled his results; he had examined the two mechanics in a garage where ethyl petrol was used, but not corresponding men in other garages where it was not used. His investigation was a private affair, and it was a question of money, and of opportunity for making tests.

Sir Charles Martin asked whether, if a person remained for an hour in a traffic block in Piccadilly, among cars using ethyl petrol, he would run any risk of lead poisoning from exhaust gases. Dr. Coplans replied that this might be the case in a narrow street with a great deal of traffic and in the case of a person repeatedly subject to such conditions. Sir C. Martin thought such a person would suffer from carbon monoxide poisoning far sooner than from lead. In an hour, if it was granted that a man might breathe 0.5 mg. of lead, he would at the same time be absorbing some 300 c.cm. of carbon monoxide, which would half saturate his blood. In reply to the suggestion that he had exaggerated the danger of exhaust gases in a confined area, Dr. Coplans denied any such intention, but said that it was the ordinary practice in public health, in addressing the public, to speak not with scientific exactness, but in such a way that warnings would be regarded. The point was that lead was a cumulative poison, and the constant breathing of even one-third of a milligram per hour was a wrong thing to permit. Sir C. Martin said that one would have to stand in a traffic block for six hours, according to figures which Dr. Coplans had supplied, to get the 2 mg. of lead which were said by one authority to be the industrial limit for a working day. Was anybody going to stand six hours in a traffic block? With regard to the mechanics, did Dr. Coplans feel justified as a scientific man in drawing any conclusion whatever from the trace of lead in the faeces of one of them, when he had not examined the excreta before the man was so exposed? Dr. Coplans agreed that no proper conclusions could be drawn from one or two such cases, but he thought it justifiable to keep such a man under medical observation. Asked whether, in view of the fact that there must be large numbers of employees in America constantly exposed to this risk in garages, he knew of a single substantiated case of lead poisoning in America, apart from persons employed in the mixing and manufacture of tetra-ethyl lead itself, he submitted a report of the International Labour Office of March last, and also quoted from the *Journal of the American Medical Association* on February 25th, 1927, which stated that the Standard Oil Company of New Jersey had settled the case of certain tetra-ethyl gas victims by the payment of 350,000 dollars. Professor W. E. Dixon said that he had read that report, but he thought the damages were paid for accidents in the manufacture.

In reply to Professor Dixon, the witness said that he did not suggest that the mechanics he had examined had any signs of lead poisoning. He was aware that lead was used medicinally—in great quantities in dysentery, for example—but the trouble arose when repeated doses were given over a great length of time. Professor Dixon pointed out that there were other sources of lead poisoning besides tetra-ethyl lead, and asked whether, if all these lead hazards were diminished, the danger of ethyl petrol would not be completely negligible. Dr. Coplans could not agree. Asked whether, if a man took 1 mg. of lead a day, he would get lead poisoning in five years, Dr. Coplans thought it more likely to be a few months, not five years. Professor Dixon further suggested that the results of certain experiments with lead on his own skin, which Dr. Coplans had carried out, might be due to a purely adsorption effect. Lead acetate, for example, put on the skin, could not be washed away; it would have to be scraped.

In reply to Sir William Willcox, the witness said he was aware of Blair Bell's experiments with colloidal lead in the treatment of cancer, and knew that sometimes toxic effects resulted. The point about lead was that it was a slowly accumulating poison. It might be a matter of months or years before it was eliminated, whereas with carbon monoxide absorbed from exhaust gases in a garage elimination would be merely a matter of days. With regard to water contamination, Sir William Willcox pointed out that lead ethyl was a lipid soluble, and the presumption seemed to be that it would stick to the oil rather than go to the water. Dr. Coplans, however, said that the results of experiments proved that it went to the water. The last member of the committee to cross-examine Dr. Coplans was Dr. J. C. Bridge, in reply to whom the witness said that he would certainly schedule lead ethyl as a poison.

\* A report of the proceedings at the first ordinary session of the committee was published on May 5th (p. 770).

## Scotland.

### Morison Lectures at Edinburgh.

THE Morison Lectures for 1928 at the Royal College of Physicians, Edinburgh, were delivered on May 7th, 9th, and 11th by Dr. John Carswell, who took as his subject "Psychology and medicine." The lecturer recalled that the late Sir William Gairdner had been Morison Lecturer in 1879, and had insisted on the importance of the cultivation of a psychological habit of mind among physicians. He had suggested that the symptoms of disease should be regarded as an effort on the part of the bodily organs to carry on the functions of the body under adverse conditions, and this applied particularly to manifestations of mental disease. The lecturer considered that the trend of recent research on nervous structures and functions, and its bearing on psychology as an aid to the practice of medicine, was particularly valuable, and should be closely studied by medical men. He referred in particular to the work of Hughlings Jackson, who had advanced the theory that the symptoms of mental disease should be regarded as manifestations of the dissolution of function, so that those mental functions which were the most highly developed and the latest acquired were the first to disappear when anything occurred to interfere with the working of the brain; the more primitive functions then tended to appear as symptoms. The lecturer also referred in particular to Sir Henry Head's work on aphasia and kindred disorders of speech, and notably to his doctrine of vigilance, in which hysterical manifestations were regarded as due to special parts or special functions of the nervous system becoming unusually active. The lecturer showed how anatomical lesions such as those producing aphasia could be linked up with disordered physiological, and therefore psychological, states, and he entered a plea that psychology should be based upon considerations of the same problems of physiology that were generally regarded as entering into the causation of physical disease. He believed that advances in psychological medicine would come especially along such lines.

### Conference on Mental Health.

A conference was held on May 11th at Edinburgh under the auspices of the Scottish Association for Mental Welfare. The representatives attended from various public bodies in different parts of the country, and Lord Murray presided. The chairman remarked that this association had on its roll 40 parish councils, 25 education authorities, 19 town councils, 6 district boards of control, and various other organizations, and the organizing secretary, in a report upon the year's work, showed that twenty-two local committees were now in existence, working both in industrial towns and in rural areas, where occupational centres were being set up for the training of low-grade mental defectives. The chairman further declared that he was convinced that a large class of mental defectives existed for whom there was a clamant need of more extended resident accommodation. Beyond this large class there were a vast number of cases on the border-line which could only be effectively dealt with by kind-hearted men and women. Dr. G. A. Anden, school medical officer for Birmingham, read a paper on "The borderlands of feeble-mindedness," in which he said that there had been too great a tendency to attempt the study of mental welfare in isolation from its cognate problems. If capacity to conform to the standards and inhibitions set up by the community were taken as the criterion, then individuals who showed defects of temperament and character formed a menace to the well-being of society far greater than that offered by those who were called feeble-minded. Character implied a degree of permanence and stability of conduct, and lack of these qualities constituted what was popularly termed a weak character. In the light of recent developments in psychology the mainsprings of conduct were regarded not as the intellectual qualities of reason and judgement, but the emotions which had come to be associated with the activities of the endocrine glands. The regulation of bodily growth was also a function of these organs, and thus a

definite relation had been established between bodily and mental function which explained the frequent presence of stigmata of degeneration in individuals to whom the term "devolutive" might be applied. A lengthy discussion followed the paper, and it was resolved to ask the Government to extend to Scotland the provisions of the 1927 Mental Deficiency Act for England. Dr. Kate Fraser, speaking on mental welfare in the United Kingdom, said that this country was ahead of America in regard to after-care. Committees established in America with a view to improving conditions in mental hospitals had now become an organized social movement, which conducted a vigorous educative campaign, drawing attention to the importance of mental health in regard to social problems. Definite scientific investigation into the cause of mental deficiency was still much wanted.

A discussion on the responsibility of local authorities was opened by Mr. Bertram Talbot, chairman of Roxburgh Education Authority, who said that more unified control was needed in tackling this important question. He would suggest that the body primarily responsible for the whole matter should be the education authorities of Scotland, to the care of which children from the age of 5 years onward were committed, and which could be used for the primary duty of discovering what was abnormal in the child. A member of the audience at this point interrupted to ask why parents were being ousted. She considered that the interference of the social worker had done an immense amount of harm. If parents nowadays punished their children they were called cruel. She disapproved of this interference with the home life of children and the putting of them into institutions. Many a naughty child grew up to do more good than many a child with a smug appearance who had been passed over by the social worker.

Dr. Drever, reader in psychology in Edinburgh University, speaking on the "Basal principles in mental testing," said that mental tests were generally distrusted, and had frequently been ridiculed in the press. This was partly the fault of the psychologists, who had made a needless mystery about the mental testing, and had mixed up practical questions with abstruse psychological and mathematical theories. Mental tests should be used for practical purposes, and it should be possible to give a clear and intelligible answer as to what mental tests were used and why they were employed. Behaviour of the individual was the only way in which mentality could be satisfactorily judged, and mental tests should be able to determine whether an individual possessed a certain knowledge, capacity, or ability. Thus any mental function which developed with age could be tested on precisely the same principles as were used for tests of sight or hearing. A child's ability to profit by ordinary school education could in this way be tested quite satisfactorily, and the result reached might be called general mental efficiency, or school aptitude, or by some such name. Everyone who had experience of mental deficiency laws recognized how unfortunate was the legal and current use of the term "deficient," and even of the term "feeble-minded." It would be far better to speak of mental retardation or to use some similar non-committal term. Intelligence had many aspects. It might be abstract and be shown in the ability to deal with ideas and symbols, or be concrete in the ability to deal with facts, or be social in the ability to deal with people. The tests usually employed to diagnose mental retardation had been largely tests of the abstract type, and the education in the ordinary school placed a premium on this type of intelligence. Performance tests would be a test of concrete rather than of abstract intelligence.

### Highland Hospital Extensions.

As intimated in the *British Medical Journal* on May 12th (p. 821) Dr. Walter Elliot, Under Secretary of State for Scotland, last week performed several important functions in connexion with the development of hospitals in the Highlands and Islands of Scotland. The first function was the laying of the foundation stone of the reconstructed Northern Infirmary at Inverness on May 8th. In connexion with the ceremony a conference of fourteen provosts from towns of the northern counties, and of members of the medical profession and of various local authorities, was held

in the Town Hall, Inverness. Dr. Elliot, opening the conference, said that the position of hospital accommodation in Scotland required the closest attention, and it was very important that they should move in the right direction. With regard to the voluntary system of hospitals, the Scottish Board of Health desired to confirm, maintain, and extend that system. It was impossible, however, that the whole hospital organization of Scotland could be effected under the voluntary system, which in some remote places suffered from financial limitations. At present the voluntary hospitals in Scotland provided 9,000 out of 25,000 hospital beds, and these figures gave the key to the development for which they must look in the future. He wanted that day to discuss particularly the question of co-operation between the Northern Infirmary at Inverness and other hospitals in the North, such as those of Fort William and Dingwall, and to see how far co-operation was possible between the Northern Infirmary and these other hospitals. The problem of hospital co-operation touched the future development of local government in many intricate ways; he believed that along the lines of co-operation lay the real future for the development of the voluntary hospital system. After some discussion it was decided to ask local voluntary hospitals to nominate representatives for the purpose of forming a voluntary regional hospital committee. It was announced by the honorary secretary of the Northern Infirmary that Mr. Alexander Edward of Forbes had presented to the Northern Infirmary the estate of Kintail, one of the best sporting estates in the West of Scotland, with a rental of over £3,000 and an estimated value of about £45,000. On May 10th Dr. Elliot formally opened the enlarged Stornoway hospital and the extended Lewis sanatorium, to which reference was made in last week's issue.

#### Hospital for Crippled Children at Edinburgh.

The committee which was appointed in Edinburgh some time ago to make provision for the care of crippled children in the south-eastern counties of Scotland has secured a site for a hospital on the outskirts of Edinburgh, and arrangements are being made for major and minor clinics for cripples throughout the area. The site for the new building is at Fairmilehead, some three miles to the south of the city. The hospital will be pleasantly situated on rising ground, with a view of Edinburgh in one direction and of the Pentland Hills in the other. A sum of £20,000 has already been promised, but £55,000 is still required for the completion of the scheme. The Edinburgh Corporation has meanwhile voted a sum of £500 from the Common Good Fund. Local efforts are in progress in East Lothian, Midlothian, Berwick, Fife, Clackmannan, and Kinross to raise money, and a flag day is being held in Edinburgh on May 5th. This is the first organized movement in Scotland to secure treatment for cripples at an early stage by means of an orthopaedic hospital linked up with local clinics, where children suffering from diseases likely to lead to crippling can, in the first place, apply for treatment, and to which they can be subsequently referred for after-treatment. The hospital will be suitably placed in respect of fresh air and sunlight, and will be sufficiently near the city to secure the regular supervision of surgeons, physicians, and trained nurses.

#### Health of Dunfermline.

The second annual report since the appointment of a whole-time medical officer of health for the burgh of Dunfermline has just been issued by Dr. C. Barclay Reekie, medical officer of health for Dunfermline, and notes advance in several directions. The total number of cases of infectious disease, of which the chief was scarlet fever, shows a decrease from 591 in 1906 to 477 in the year under review, and is closely comparable with the figures of 441 for 1924 and 463 for 1925. Of the 161 cases of scarlet fever notified, it is pointed out that 65 per cent. occurred among children of school age; the largest number occurred in October and the smallest in July. Infection is attributed generally to cases regarded as "sore throat," which were in fact mild atypical cases of scarlet fever, remaining at school until their recognition during the "peeling" stage. Seventy-five cases of diphtheria were notified, of which 60 per cent. were of school age and under, but there were

no deaths from this cause. Influenza assumed epidemic proportions in January; and notification was adopted; 1,539 cases were reported, with a mortality of 23, or 1.5 per cent. Insulin was supplied at the expense of the local authority to persons in necessitous circumstances suffering from diabetes. Of pulmonary tuberculosis there were 47 notifications as compared with 61 in 1926, and 18 deaths were registered as due to this cause. Of the notified cases, 15 received sanatorium treatment. Administrative control included the visitation of all notified cases by a tuberculosis nurse, acting as health visitor, giving advice with regard to prevention of infection, etc., and inviting the patient to attend at the tuberculosis dispensary. The total number of visits paid in this way was 1,098. The tuberculosis dispensary was in operation for eight months during the year, and in this period there was an attendance of 492. Three health visitors were employed by the burgh, of whom one was the tuberculosis nurse. The infantile mortality rate was 78 per 1,000. The total number of attendances at the two child welfare clinics for children under 1 year was 2,263, and of those over 1 year 1,000. The maternity home was largely utilized, as was shown by 214 admissions during the year.

## England and Wales.

### Medical Women's Federation.

THE gratifying progress of the Medical Women's Federation was demonstrated at the annual dinner, which was held in London, at the Hotel Victoria, on May 10th. Dr. Christine Murrell presided, and among the guests were Lord and Lady Balfour of Burleigh, Sir Robert Bolam, Sir Walter and Lady Fletcher, Mrs. E. D. Simon, Mrs. Philip Snowden, Dr. Graham Little, Professor Grey Turner, Sir Gregory Foster, Sir Herbert Waterhouse, and Major-General J. B. Smith. Sir Robert Bolam, proposing the toast of "The Medical Women's Federation," spoke of the early days of the entry of women into medicine, and paid a high tribute to the work of the Federation. He discussed its relation with the British Medical Association and promised sympathetic co-operation. Dr. Letitia Fairfield, who replied, emphasized the value of comradeship of men and women in the medical profession, but insisted on the importance of women working together as a unit if the best results were to be obtained. She mentioned the gratifying increase in membership of the Federation, and gave illustrations of the special work in which women were pre-eminent. Attention was drawn to the recent successful international meeting at Bologna, and to the good results that had attended the work of the Federation in helping and encouraging medical women who were starting in practice. Dr. Clara Stewart, one of the original members of the Federation, proposed the health of "The Guests," and in reply Mrs. E. D. Simon contributed a very witty speech dealing with the relations of men and women. Sir Walter Fletcher, who also replied to this toast, paid a warm tribute to the advance in medicine which had followed the entry of women into its practice and study. Medical art and science had been enriched by the special gifts they had brought, and he referred particularly to the services they had rendered to statistical inquiries, the study of nutrition, and the use of radium. Professor Lucas Keene, proposing the health of the chairman, paid a warm personal tribute to the value of the work of Dr. Christine Murrell, and commented on the affection and esteem in which she was held by all. The chairman briefly responded, and so brought to a conclusion a very successful and enjoyable evening.

### Maternal Mortality: Minister of Health at Leeds.

The Minister of Health, Mr. Neville Chamberlain, was, on May 8th, the guest at a luncheon in Leeds Town Hall held to advance the work of the Leeds Maternity Hospital and the Leeds Babies' Welfare Association. Mr. Chamberlain, in his address, devoted himself to explaining the policy of the Ministry of Health in relation to the problem of maternal mortality. During the nine years of the

Ministry's existence, he said, the general death rate of the country had fallen from 14 per 1,000 to 12.3 per 1,000, and infant mortality from 89 per 1,000 to 70 per 1,000 in 1927; but it was an unhappy and regrettable fact that the maternal mortality rate had for the past twenty years remained practically stationary. It was in circumstances like these that it was the duty of the Ministry to stimulate all the efforts which were being made to cope with this blot upon their civilization. Mr. Chamberlain then referred to the committee of investigation he proposed to establish to deal with the causation of maternal mortality, an account of which was given in the *Journal* of April 28th (p. 729), saying they hoped by this means to get available information which would throw new light on the dangers they were providing against. That they believed would be very useful to the Ministry in its campaign against maternal mortality. What was needed was more supervision, both ante-natal and post-natal, more opportunities for consultation, and more beds in maternity hospitals. Finally, there was wanted more education of the public, which would then understand more of the instructions given, so that it would carry them out wholeheartedly. He then emphasized the importance of attracting into the profession midwives of the right type; their training was not so complete as in some Continental countries. Accordingly he had just appointed a strong committee to investigate the training of midwives and their working conditions. The pressure and support of public opinion would be required if the recommendations were to be carried into effect. Mr. Chamberlain concluded by saying that he believed that in all the fields of public health there was no more noble or fruitful section than that to which they were devoting their efforts.

#### The London County Council and Compulsory Vaccination.

The City Council of St. Albans has asked the London County Council to support a resolution passed by it to the effect that in view of the increasing prevalence of small-pox in this country the law should be amended so as to provide for compulsory vaccination and revaccination; further, that the medical officer of health should have power to isolate contacts or suspects for such period as he might deem necessary. The Public Health Committee of the London County Council, however, considers that in the present state of public opinion it would not be wise to attempt to impose any further measure of compulsion in regard to vaccination. "This does not imply that the value of vaccination is in any way considered by competent medical opinion as having diminished. The contrary is the case." But the whole question of vaccination is under consideration by a departmental committee, the report of which is expected shortly. With regard to the compulsory isolation of suspects and contacts, the Public Health Committee states that the present outbreak of small-pox of a relatively mild kind which has been prevalent for some months is being spread by persons of the vagrant class who frequent the casual wards of Poor Law institutions, and there are no powers of controlling adequately their movements in the present emergency. It is considered doubtful whether any strengthening of control would not defeat its own object, since it would lead to avoidance of the casual ward. One objective of the Ministry of Health in dealing with the present outbreak is to keep all casual wards open and thereby to have all tramps under close observation. The closure of the wards would disseminate rather than restrict the spread, and drive casuals into common lodging houses. It is also pointed out that the present outbreak is less menacing than previous ones. It appears to be a fixed variant of small-pox differing from the normal disease in many respects, of which the most significant is that it is not fatal. It is frequently mistaken for chicken-pox, which in Paddington and the Port of London is already notifiable, while other metropolitan borough councils are considering obtaining similar powers. Propaganda in regard to small-pox is a matter primarily for the sanitary authorities responsible for the prevention of epidemic diseases in their areas. The officers of these authorities and those of the council work in close co-operation, and any assistance and advice which the council's officers can afford is readily

given. In all the circumstances the Public Health Committee is not prepared to advise the London County Council to support the St. Albans proposal.

#### Central Midwives Board.

The Central Midwives Board for England and Wales met on May 3rd, with Sir Francis Champneys in the chair. The standing committee reported that it had been in communication with the midwifery boards of certain of the States in the British Empire concerning the conclusion of reciprocal arrangements for the registration of midwives. It was proposed that the English Board should undertake to place on its roll the names of midwives who produced a certificate of registration granted by the State board concerned, after examination, provided that the State boards would similarly accept the English qualification. The arrangement would not apply to midwives holding the English Board's certificate granted by virtue of their having been in bona fide practice prior to 1902, while the acceptance of other certificates in England is governed by certain conditions regarding training and experience. It was reported that a letter had been received from the Nurses' Registration Board of South Australia agreeing to an arrangement on this basis, and the Central Midwives Board therefore adopted a resolution giving effect on its side to the proposed reciprocal agreement.

## Ireland.

#### Free State Medical Registration.

Medical practitioners desirous of having their names placed on the Irish Free State Medical Register are reminded that May 26th is the last day for receiving applications for registration without a fee. After that date a fee of £5 will be charged. Every practitioner whose name appears in the general *Medical Register* before May 26th will be entitled to have his or her name entered in the Free State Register if application is made within the prescribed time; those with Irish Free State addresses will be placed automatically in the Irish Register, and therefore need not make personal application for registration. Details were given on April 21st (p. 686). Medical practitioners in Northern Ireland whose practice extends into the Free State should have their names in the Free State Register so that they may have the legal right to sue for fees for treating patients resident in Southern Ireland.

#### Lady Dudley's Nursing Scheme.

The committee of Lady Dudley's nursing scheme, in the twenty-fifth annual report, states that the assured annual income is seriously depleted from now on by the loss of a grant of £500 a year from the National Health Insurance Commissioners, through the funds from which it was drawn being entirely exhausted. The committee has, since 1918, had this £500 towards the work of six districts, and to replace the sum this year will require a considerable effort. The Irish Peasantry Society has generously promised £150 a year to establish a nurse at Bruckless, county Donegal, on the express condition that it is only given so long as the remaining twenty-five districts are kept open. A nurse is already installed there, and her services are deeply appreciated. The beginning of a new decade in the committee's existence is regarded as a fitting time for the launching of an appeal for fresh support. The loss of £500 a year mentioned above jeopardizes the work of the twenty-six nurses already established, and along with this anxiety there are insistent calls for nurses in new districts which cannot well be ignored. These emanate particularly from three areas; from Achill Sound the demand is for a return of the nurse after experience of her work in the years 1920-25, when it was found necessary to close the district, partly owing to want of funds and partly because a suitable residence could not be found; second, from Sneem in county Kerry; third, from Malin Head, county Donegal, for whose claim the committee pleaded in its last report. In these districts there are no people of substance to assist the movement, and any help in the form of money must come from outside:

## Vaccination in the Irish Free State.

The debate on the second stage of the Vaccination (Amendment) Bill was concluded on Friday, May 11th. The main feature of the bill was the provision of a clause for conscientious objectors. President Cosgrave spoke strongly against the bill, while Mr. de Valera, Leader of the Opposition in the Dail, supported it. During the debate nearly all the medical members of the Dail made speeches against the proposed measure. Dr. J. Ryan, one of the members for Wexford—the only county in Ireland where the antivaccinationists have any considerable support—stated that he believed in the protection afforded by vaccination, but as a considerable section of his constituents were opposed to compulsory vaccination he would vote for the bill. On the second reading the bill was rejected by 75 votes to 39. Before it was introduced and while it was before the Dail members were liberally supplied with the usual antivaccinationist literature from London.

## Correspondence.

## IMMUNITY FOLLOWING HERPES ZOSTER.

SIR,—In the recently published paper by Dr. Max Obermayer, of which a brief summary is given in the *British Medical Journal* for May 12th (*Epitome*, p. 79, No. 461), an objection is set up to the teaching that an attack of true herpes zoster confers lifelong immunity. But the objection is grounded on a case which appears to me a typical one of "recurrent herpes of the buttock." The patient (a medical man), aged 32 years, in the course of a few years (the first attack was in autumn, 1924) had had eleven recurrent attacks of left gluteal herpes. Such cases are analogous to cases of recurrent facial herpes on the cheek, and, like the latter, may be indistinguishable from cases of true herpes zoster, excepting by their recurrence. I am certain that recurrent herpes, occurring on either the cheek or the buttock or the thigh, has often been diagnosed (and sometimes published) as true herpes zoster, and, indeed, the etiology of recurrent herpes is obscure. But before the cause of recurrent herpes has been proved to be the same as that of true herpes zoster, arguments for the possibility of the recurrence of herpes zoster cannot be based on the recurrence of what is known in the literature of the subject as "recurrent herpes." I will here refer only to H. G. Adamson's paper on "Recurrent herpes of the buttock" in the *British Journal of Dermatology* (1911, xxiii, p. 322), and the articles by Dubreuilh and others quoted by him. To cases known to myself I may refer on another occasion.—I am, etc.,

London, W.1, May 14th.

F. PARKES WEBER.

## ORAL ADMINISTRATION OF PANCREATIC PREPARATIONS.

SIR,—It was with great satisfaction that I read Dr. Fuller's article in your issue of May 12th (p. 798) proving the uselessness of certain pancreatic preparations widely used in the treatment of diabetes, and pointing out the reason why they sometimes seem effective—namely, the simultaneous adoption of a restricted diet. The experience of all investigators who have carried out fully controlled tests is that oral pancreatic preparations are all quite useless. Professor MacLean and myself published in your columns last year a condemnation of all such preparations that we had tested.

Unfortunately such articles as Dr. Fuller's are probably read by only a small part of the medical profession and not by the public at all. On the other hand, ingeniously devised advertisements are universally distributed to doctors, and, as it is easier to have a pill than an injection of insulin, the use of these oral preparations still goes on widely, often with calamitous results, as the following case illustrates. This year one of my severe insulin cases was persuaded by friends and a "specialist" who undertakes the oral cure of diabetes to substitute her insulin by an oral preparation, with the result that she was soon rushed into hospital by the alarmed "specialist" in a deep coma.

In the last two months I have been assailed, as no doubt most doctors have, by advertisements extolling the virtues of certain pancreatic preparations for oral use in diabetes. I have satisfied myself by careful tests that they have no value whatever. But, though I may crave space to say so in your columns, I cannot circularize the whole of the medical profession (even if they would take my word for it), and no doubt these preparations will continue to be widely used, to the benefit of no one except the manufacturers.

It seems to me that the public should be protected against the harm that the widespread advertisement of such "remedies" may cause. No doubt the manufacturers often act with perfect faith in the efficacy of their preparations, but they are not competent to judge their value. It matters little, of course, whether the public wastes its money on the thousands of proprietary remedies for minor ailments which do neither harm nor good; but it seems monstrous that, in a severe disease for which there is the potent remedy insulin, useless preparations can be brought into such wide use as to supplant the proper use of insulin, and cause unnecessary ill health and death to many diabetics.

No doubt there are large financial and legal difficulties to be overcome before the public can be adequately protected. The American medical profession, however, is much better warned against such preparations than we in this country, largely owing to the publicity given to the subject by the American Medical Association. May I suggest that much might be done in this country if the British Medical Association gave a similar official publicity to the analysis and properties of such remedies?—I am, etc.,

London, W.1, May 12th.

R. D. LAWRENCE.

## TROPICAL AUSTRALIA.

SIR,—Sir James Barrett, by his letter on the above subject which appeared in the *British Medical Journal* of May 5th (p. 772), has kindly replied to my communication of January 7th (p. 30). He has given some interesting facts and figures, but I regret that he has not answered my question, while he has attributed to me a statement which I never made. I did not suggest—and anyone who reads my letter carefully will see that this is the case—that the white race in tropical Queensland is of Italian origin. Having been told that the white men who labour in the cane fields of the low-lying littoral of Queensland are very largely of Italian origin, I asked if this were true. I said nothing about Queensland in general. Having seen a good deal of the Queensland contingents both in the South African war and in the great war, I am well aware that this vast territory produces fine specimens of humanity.

The point is not in dispute. All I want to know is what percentage of white Queenslanders who carry out manual labour in the open, under the trying conditions obtaining in the coastal region, are Italians or of Italian origin. It should not be difficult to supply this information, so I appeal again to Sir James Barrett for a reply, as the matter is of considerable interest and importance from a scientific standpoint.—I am, etc.,

London, W.C.1, May 9th.

ANDREW BALFOUR.

## THE "CURE" OF PULMONARY TUBERCULOSIS.

SIR,—In a former letter (April 21st, p. 692) I criticized Dr. W. M. Crofton's "cure" of pulmonary tuberculosis, in so far as it concerned the use of a tubercle vaccine, from the point of view of a student and practitioner of Koch's classical methods. Dr. Crofton's figures in reply (May 5th, p. 773) induce me to make, in addition, a comparison between his system and that of Sir Almroth Wright, which is the most notable departure from Koch's method so far elaborated.

Working under the guidance of the opsonic index, Sir Almroth Wright developed a system of minimal dosage, designed not so much to effect actual immunity as to promote beneficial immunizing responses in the infected patient, and there is no doubt that his extraordinarily minute doses do actually bring about changes which are sometimes beneficial. The minimum effective dose of

Wright's school, for severe infections, has been placed at 1/500,000 mg., while the upper limits are somewhat similar to those of Dr. Crofton.

Dr. Crofton's figure 0.000000001 mg. is therefore 1/2,000 part of Wright's minimum effective dose, and Dr. Crofton's system of dosage would appear to be a variant of Wright's, in the downward direction.

What these figures really mean may be realized by an effort to visualize them. The quantity 0.000000001 mg. of tubercle bacilli is an amount in bulk at least two thousand times below the point of naked-eye visibility. To change the effort, one drop of Koch's B.E. would require to be added to a small swimming bath containing over 10,000 gallons of water in order to give in 1 c.cm. the equivalent of Dr. Crofton's initial "potent therapeutic dose," which "must not be exceeded as a primary dose in the immunization of established pulmonary tuberculosis."

This method certainly ought to be safe.—I am, etc.,

Wandsworth, May 7th.

ROBERT CAUSWELL.

#### DEAD AND INFECTED TEETH.

SIR,—At the recent congress of the Ophthalmological Society of the United Kingdom I described some of the findings in 100 consecutive patients, seen in private practice, who attained full normal vision after the prescription of spectacles. I omitted from the series thirty-nine patients who did not reach this standard of vision owing to some obvious pathological condition of the eyes. The results obtained have a bearing on the subject of "dead and infected teeth," concerning which there is a correspondence in your columns.

In the course of complete ophthalmic examination by modern methods certain slight changes were found in the eyes of some patients suggestive of toxic absorption due to the presence in the body of some septic focus. I attempted to elucidate the whereabouts of the focus if present. For those who had crowned teeth, or other obvious dental defect, dental radiographs and the opinion thereon of the patient's usual dental surgeon were obtained. In other cases the indication was to refer the patient to a surgeon, a physician, or a rhinologist, operations being required in four cases. Seven patients refused advice as to medical or dental investigation, and in eight cases the examination was incomplete. The dental cases may be summarized as follows:

	No. of Patients.
Referred to dental surgeons ... ..	42
Dental radiographs obtained ... ..	33
Apical abscesses shown by radiographs and in most cases confirmed by dental operation ...	22
Buried fragments of previously extracted teeth shown in radiographs ... ..	5
Unrupted teeth, mostly impacted ... ..	8

Lantern slides of a selection of the radiographs were prepared by Dr. Goldwell and Dr. Alchin, and were demonstrated at the congress by Dr. Livingstone of King's College Hospital Dental School, to whom, and to my dental colleagues at Westminster Hospital, Mr. Bowdler Henry and Mr. Frank Lawrence, I expressed my great indebtedness for help extending over several years; also to Sir William Willeox, who spoke at the meeting.

The paper will be published in the *Transactions* of the Ophthalmological Society, with full details of each case; the usual abstracts are being circulated to the medical journals, of which this letter is an abbreviation. The clinical results arrived at appear to be of importance to dental surgeons, as I suggest that the 100 consecutive private patients with full vision of my series may be considered as fairly typical of the social class which employs London consultants.

At the meeting of the Section of Odontology of the Royal Society on February 27th I stated my belief that the breaking down of resistance to absorption of toxic material from the teeth may be detected at an early stage by ophthalmic examination, and I enumerated some of the first signs of toxic absorption in the eye.—I am, etc.,

London, W.I., May 13th.

A. F. MACCALLAN.

SIR,—It was with great interest and hopeful anticipation that I read Mr. Jennings Marshall's letter in your issue of April 28th (p. 731).

With the first part of his letter I am in entire agreement, for I know from experience that it is usually the wrong type of case that is sent for extraction of all teeth as part of the treatment. I find that not a few medical men send their patients for complete oral radiograms, and where any areas of rarefaction are seen about the roots advise extraction of these teeth. This advice is given without any supporting clinical evidence that the teeth are pathological, or without consulting the patient's dentist. When the patient later visits the dentist the latter is often placed in a very difficult position.

One would have thought that the stage where x-ray evidence, unsupported clinically, was accepted had passed. I do not think that any practitioner would dare to order radical treatment in other conditions on x-ray evidence alone. Furthermore, I would respectfully suggest that the decision with regard to the dental treatment necessary in any particular case be either left to the dental surgeon or arrived at in consultation with him. Whatever procedure is adopted I consider it wrong to send a patient to the dentist with instructions as to dental treatment. Should there be instructions, these ought to be sent to the dentist direct, and not through the medium of the patient. This would avoid many an unpleasant situation, as I mentioned before, as frequently an explanation by the dentist will cause the medical man to modify his opinion.

This brings me to the second part of Mr. Marshall's letter—the part in which my hopeful anticipation received a set-back. He refers to the treatment of teeth in which the pulp cavity has been infected as a "surgical heresy." I fail to see his reason for this. Surely it is not a "surgical heresy" to render an infected organ aseptic and so enable it to be retained as a useful member. The treatment of molar teeth with septic pulps has, by very many practitioners, been abandoned as almost hopeless. This is owing to their being multi-rooted, the roots often being tortuous, rendering the proper cleansing and drainage of the root canals a practical impossibility. However, when it comes to teeth with single roots—for example, the incisors or canines—and where a radiogram shows these roots to be suitable, these can be treated quite successfully.

One would not expect a medical man to draw conclusions from such limited knowledge of any subject, such as I respectfully suggest the knowledge of dental surgery must be to a medical practitioner. A little knowledge may even be dangerous to the scientific mind.—I am, etc.,

GEORGE A. COWAN, M.B., B.Dent.Sc.

London, W.I., May 9th.

#### THE CAUSES OF ALCOHOLIC INEBRIETY.

SIR,—Long experience of inebriety in all forms makes me agree entirely with Dr. Carver (May 5th, p. 774) that the inebriate, whether alcoholic or morphinist, is in every case primarily the subject of a neurosis. The difficulty or otherwise of his cure depends on the curability of his neurosis, together with the fact that he has found the flight from his complex or complexes into alcoholism or morphinism so much easier and more satisfactory to him than facing reality, though he knows from painful experience the price he must pay for his temporary relief. Anyone who has had any considerable experience of the alcohol inebriate must have noted what Dr. Carver points out, and what I have commented on elsewhere (*Pathological Inebriety*; Ballière, Tindall and Cox), namely, the inebriate's disgust at the "dope" he finds necessary. I have often, unseen, watched the inebriate dally with a stiff dose of whisky for half an hour or so before making up his mind to toss it off like a nauseous draft of physic, heaping curses on himself and "the stuff" meanwhile. I consider the causes of such inebriety, then, to be: (1) neurosis; (2) the accidental discovery of the relief to be obtained in alcoholic or other narcotic euphoria; (3) the depressant reaction of the narcotic, which is more distressing or less bearable in the case of the neurotic than in a person of sound mental integrity, and so aggravates the already present urge of the neurotic complex as to

make a resistance to the mental and physical craving well-nigh irresistible. I entirely agree also with Dr. Carver that the alcohol or morphia addict has no desire to be incapably intoxicated, but is unable to control his narcotic dosage so as to maintain just the desired euphoria which will relieve distress without overstepping the mark. I have once only seen an addict who was able to exercise such self-control over the dosage of morphia; I have never seen it in regard to alcohol. In this particular case the addiction was of fifteen years' standing, during which period the addict had never exceeded 3 grains in the twenty-four hours, and had in consequence managed to keep his addiction secret even from his wife.

In regard to heredity, I am of opinion that it is the neurotic constitution which is hereditary and makes the subject of it potentially, but by no means necessarily, an inebriate.—I am, etc.,

Middleton St. George, May 6th.

J. W. ASTLEY COOPER.

#### SEA-SICKNESS.

SIR,—While there are few who will dispute Dr. Allan Bennett's treatment for sea-sickness (May 5th, p. 752), there are a great many who would join issue with him on the causal agencies of that disorder.

The vast experimental evidence on the labyrinth, apart from the indisputable witness afforded by trauma and disease, makes the vestibular centre of fundamental importance in vertigo of all kinds. The haphazard observations regarding a punctured drum and double mastoids are not pertinent, since in neither case was Dr. Bennett able to speak of the labyrinth, which, it is elementary to state, often escapes in such lesions. The vestibular centre is in certain types extraordinarily sensitive to all sorts of influence, both proprioceptive and exteroceptive, and so the illustrations which suggest an independent centre are also not pertinent, since in none of these is it denied that there may be almost any type of stimulus acting as a signalizer, and operating singly sometimes, but none the less effectively. The kinaesthetic, the optical, the olfactory, and the psychical may one and all be involved. It is therefore discursive to instance the case of the strong-minded person ascending a ship's gangway being overcome with nausea as showing the relative unimportance of the vestibular centre merely, because the kinaesthetic sensations are not directly involved.

There is no case of Dr. Bennett's that does not ultimately illustrate either the native sensitivity of the vestibular centre or how its threshold may not be lowered. It is superfluous to deny the interaction of other nuclei, but it is poor observation to suggest the pneumogastric as a sort of independent centre. Sympatheticotonia and vagotonia in severe cases of sea-sickness follow in disturbingly and antagonistic succession, or may in part act together. These represent merely the overflow from the neighbouring nuclei, the ultimate centre in every case being the vestibular nucleus.

Advice for the treatment of sea-sickness has become trite, nevertheless attempts to close the varying portals to signaling stimuli depend for their success on a study of the individual case; it may, in fact, be presumed that all Dr. Bennett had in mind was to emphasize what is in danger of being overlooked—that so far we have no remedy for *mal de mer*.—I am, etc.,

T. GWYNNE MAITLAND, M.D.

Cunard Building, Liverpool,  
May 8th.

SIR,—Very few ship surgeons will, I fancy, be able to agree entirely with Dr. Allan Bennett in regard to sea-sickness. Driving patients out of their warm cabins into the fresh air on deck, "however cruel it may seem," is absurd. In many instances in my personal experience—which has been considerable—going out on deck into the air has just precipitated a bad attack of *mal de mer* which might possibly have been avoided otherwise. The prostrate and helpless forms on the deck of a cross-Channel steamer on a rough day are sufficient evidence of the inefficacy of the compulsory fresh-air treatment. I have found that regular daily action of the bowels, commencing with a good

clear-out before starting on the voyage, plenty of water to drink, and the minimizing of stomach acidity and moderate eating and exercise are about as useful as any measures for preventing sea-sickness—if it can be prevented in any particular cases. When the attack threatens and the patient begins to feel ill, the only thing then to do is to go immediately to a warm and airy cabin and lie on the flat of the back—not the side, remember!

Little sips of a mixture in solution of sodium bicarbonate, liquor morphinae hydrochlor., and sp. chloroformi and ess. menth. pip. will help matters. In bad cases of acidity the stomach certainly should be washed out. Food and drink should not be pressed at all for twenty-four hours if the patient shows no inclination. In any case dry ginger ale (as suggested in the annotation) I regard as one of the drinks most likely to bring on a recurrence, and I have never permitted its use. The less aerated water a sea-sick patient has the better.

As for purgatives, salines alone are perhaps best on board ship. Before starting the voyage calomel at night followed by a morning saline would be preferable, but at sea the calomel is likely to cause a little too much liver disturbance and so produce nausea. Nearly everyone starting out on a long voyage feels sea-sick ("livery," they call it) for the first two days or so, due to changes of diet, exercises, and life in general, and, of course, also movement; but after this period is over only a very small percentage ever feel ill again if they follow the ordinary simple rules.

Bromides and atropine should not be relied on as preventives, and it should be borne well in mind that the frequent use of atropine may not only fail to prevent the sea-sickness, but may be harmful to the patient besides.—I am, etc.,

GEO. A. PEMBERTON WRIGHT,  
M.C.P. and S.Ont., L.A.H.Dub.,  
Late Staff Surgeon R.M.S. *Mauretania*.

#### ORGANIZATION OF DISCUSSIONS.

SIR,—An amenable feature of the highly successful Conference on Rheumatic Diseases at Bath was the rushing through of the papers. Many important contributions, the preparation of which must have entailed laborious hours of thought and work, had to be got through within a space of five minutes. This simply meant that the various speakers had to deliver their addresses at such a rate that made it difficult for their audience to follow them to full advantage. Furthermore, considerable sections of many contributions had perforce to be cut out. This necessity, without previous warning, was obviously disconcerting to the speakers. Thus the continuity of the subject-matter in many instances was lost. To take an instance: in the third session the time which remained for a general discussion on the subjects of three hours of mutilated papers was exactly five minutes. Small wonder that many whose views would have been of interest felt the futility of making any attempt. Surely the discussion, with its interchange of views and questionings of the principal speakers, should form an essential part of a "conference."

The remedy would be to have the contributions, which are already in print for the convenience of the press, made up in the form of a paper-covered brochure. These, on application to the honorary secretary a few days prior to the sessions, could be distributed to those interested. It would then be feasible to ask the speakers merely to deliver a précis of their observations, and to show slides or charts. These latter would then possess a greater interest to the hearers, who would have had opportunity of digesting the subject-matter. In a three-hourly session this procedure would leave probably one and a half hours for the discussion.

As a former local secretary of a Section at an Annual Meeting of the British Medical Association, I would suggest that if at the forthcoming meeting at Cardiff the Sections were conducted on these lines, it would be found to be of mutual advantage to all concerned.—I am, etc.,

Bath, May 14th.

JAMES LINDSAY.

\*\* If Dr. Lindsay had been local general secretary of an Annual Meeting he would know that what he suggests is not quite so easy as it sounds.

## BRITISH SPAS.

SIR,—I read in your columns that the British Spas Federation held its annual meeting at Bath on March 8th and 9th, and that one of the chief points discussed was the necessity for propaganda, especially in English-speaking countries. Is this shyness, lack of spirit of enterprise, or complete misunderstanding of the situation?

British spas will only be given due recognition when they attract visitors from all parts of the world. It is the Continental patient they should first of all attract. What they would give them as regards accuracy in treatment, excellence in sports, and the enjoyment of British summer they would receive back tenfold. Imagine a French colony invading Harrogate or Buxton with the merry determination of having a cure and a good time together. The very atmosphere of these spas would change, and the barometer would certainly go up a few points.

How much we do appreciate in France what our British friends have done for our spas! For instance, if Vichy boasts of the best-equipped sporting club in the country, it is them we have to thank. It is in a feeling of gratitude that two French hydrologists, Dr. Reboul and the undersigned, took the trouble to translate into French, and present to French medical circles, Nevillo Wood's book on British spas and health resorts; while in Paris and Lyons Dr. Villaret and Dr. Pierry, both professors of hydrology, have, each of them, devoted one of their curriculum lessons to British spas; and as hydrology is an obligatory quiz for an M.D. degree, candidates have to look at the hydrological map of Great Britain and to know something of the indications of your spas. But we cannot conduct propaganda on behalf of British spas without the help of British spas. Nothing is more international than a spa. Nowhere will one more surely find out that he cannot get without giving, nor can he give without getting.—I am, etc.,

GUSTAVE MONOD, M.D., M.R.C.P.,  
Past-President of the International Society  
of Medical Hydrology.

Vichy, May 7th.

FRACTURES OF THE CLAVICLE WITH  
DISPLACEMENT.

SIR,—In his article in the *Journal* of April 21st (p. 664) Dr. G. W. Milroy calls attention to the discomfort of plaster applied next the skin, and to the tendency of well-applied bandages to become loose, and he describes a modification of Sayre's method which has given him satisfaction.

Another method, and one not involving the use of an axillary pad, is to apply John Duncan's bandage (as figured, for example, in Thomson and Miles's *Manual of Surgery*) with two women standing by with needle and thread, who, as soon as the bandage is on, descend upon the patient and proceed to sew him into it, paying particular attention to every crossing. When they have finished, two broad circles of plaster, adhesive side inward, are applied on top of the bandage, one round the elbow and root of neck on the opposite side, the other horizontal and proximal to the wrist of the injured side. The women again fall to with needle and thread and sew the edges of the applied plaster to the Duncan's bandage. Fixation is so good that an Arab boy, thus trussed up, will run about and play the same day, and the combination wears well without attention.

Where roll plaster is not available something unyielding is required; I have used a horse-girth with an adult in India.—I am, etc.,

J. L. MARJORIBANKS, M.D.,  
Lieutenant-Colonel I.M.S. (ret.),  
Formerly in charge European General  
Hospital, Aden.

San Remo, April 24th.

## INFECTIOUS DISEASE IN SCHOOLS.

SIR,—The spring term has once more maintained its character for the mass production of illness in the schools. In one high-class preparatory school 63 of the 80 pupils spent some of the time in the sanatorium—43 for measles and 20 for influenza; there was one fatal case of double pneumonia. This is a distressing record; yet the school is particularly well situated, and great attention is paid to diet and other hygienic needs.

Seeing that the diseases causing these devastations are

of the air-borne variety, I made special inquiries of the sister in charge as to handkerchief habits. She said the handkerchiefs were for the most part extremely dirty and seemed to be kept anywhere. She herself allowed none, but supplied paper or bits of linen and burnt them. This method she considered successful as, except in the one case of pneumonia that could not be saved, there were no serious complications, and all the patients were well when they were discharged to their homes. It would be an interesting experiment to establish "hanky drill" in such schools, for nasal hygiene was, in this case, the only branch of personal hygiene which did not receive attention.

In certain schools where the handkerchief is looked upon as a valuable possession to guard the breath of life the control of infectious disease seems remarkable. An infant class in a poor district had no loss of attendance for illness for two successive years; the teacher had "hanky drill" daily, and kept a supply of suitable paper for the children during school hours, this being burnt at the end of the day. In a large day school for girls, where no one was allowed to be without a handkerchief and a pocket in which it could be kept free from contamination, there had been no serious epidemic for seven years. There must be many factors in the spread of air-borne diseases that cannot be safeguarded in such schools as these, so that it seems as though a deciding factor was the care and use of the handkerchief. In both schools there were many children of an age when they are usually susceptible, yet they escaped.

Handkerchief drill consists in clearing the passages as soon as possible after waking. If the first clearing is accomplished with paper in the lavatory the time spent in the drill at roll call is negligible. The important points are to keep both nostrils open wide and let out all that lurks inside. There is a widespread practice of stopping before the finish; this should be dealt with firmly, for what comes away at the end is what has been hoarded longest. There must be no following up the blow with a sniff; the innervating powers of the nose are all-powerful. The advantages include the negligible cost and the fact that the whole community can be dealt with at the same moment.—I am, etc.,

OCTAVIA LEWIN, M.B., B.S.

London, W.1, April 23rd.

## STERILIZATION OF THE FEEBLE-MINDED.

SIR,—Your notice of the bill passed in Alberta for sexual sterilization of the feeble-minded shows some misunderstandings of the position of those who support this method of attack on one of our disastrous social problems, and I should be grateful if you will allow me to bring before your readers some of the facts at present far too little known.

First, it is not sufficiently realized that the defects in practice which caused the withdrawal or disuse of sterilization laws in the United States were legal and technical, and not based on any impracticability, or, so far as the short experience of twenty years can show, want of tangible results. The conflict between Federation constitution and State constitution has, in the main, been the reason, and since the introduction into California of a reason, and since the introduction into California of a model statute, no fewer than twenty-five States had introduced, or reintroduced, an amended form before 1925. A recent case before the Supreme Court finally upheld the legality of these statutes brought up under that recently introduced into Virginia.

It is often contended, and you bring out the point very strongly, that sterilization can very seldom be of use in preventing procreation, for the reason that few cases of defectives are satisfactorily dealt with apart from detention in institutions. It is clear that the proportion will vary in different populations and will also largely vary according to the stage of culture of any given people; in dealing with a largely rural group a lower level of mentality can possibly be regarded as the normal than in a country like our own, where such a high proportion of places for employment require very considerable skill and intelligence. In any event, to-day in England the proportions of our problem are so tremendous that it may well be argued that no means should be spared to lessen the burden for future generations. We know that a consider-

able proportion of the defective children in special schools where these are best run (London and Birmingham) subsequently marry, and that their children are in many instances now forming the second generation of scholars. It is well in view of these facts to study the careful analysis of the treatment of the feeble-minded in California. Fifteen years' experience, covering now over 1,050 cases, gives an indication of the possible value of this measure. A very considerable percentage have been earning their living on parole, the most satisfactory cases being those where two feeble-minded and sterilized patients are married. A good many of these marriages have occurred.

From experience of individual cases I know how hard is the necessity in England of detaining in an institution, without an occasional holiday, patients who can certainly not be sent home without the safeguard of sterilization, but who in these circumstances might be trusted to the care of their relatives for a short period each year.—I am, etc.,

C. B. S. HODSON,  
Secretary, Eugenes Society.

London, S.W.1, April 25th.

\* It is not contended that sterilization may not be the proper procedure in a number of individual cases, but merely that the systematic sterilization of defectives is not, under existing conditions, a practical policy for the State; and that, under any conditions, the sterilization of a limited number of such persons (as now legalized in Alberta) would have little or no effect as a means of eradicating mental deficiency in a large community. A considerable proportion of higher-grade morons are not socially defective, and, after training in a suitable school, can safely be left, with a small amount of supervision, to earn a living by performing modest but useful tasks in ordinary surroundings. Whether it is a practicable proposition to insist, where two such persons propose to marry, that one of them shall submit to sterilization, is arguable. Clearly there is no safety (even in this limited field) in anything short of the systematic sterilization of all such boys and girls when they leave the special school at about the age of 16. This is not a practical proposition at present. For the rest, who are low-grade cases or who are socially as well as mentally defective, and who, therefore, are supposed to be cared for permanently in suitable institutions or colonies, sterilization is evidently unnecessary—except, as Mrs. Hodson contends, for the purpose of letting them have a short holiday each year outside the institution. This is a new argument, but surely it lacks a sense of proportion.

#### PHARYNGO-OESOPHAGEAL SPHINCTER.

SIR,—In a letter published in your issue of March 3rd (p. 375) Dr. Hurst refers to the "sphincter of Negus." Much as I should so important a fold, I regret that claim to that honour. I have made some observations as to the function of the crico-pharyngeal sphincter, but it was some years ago that I first learnt of the existence of this muscle band from the writings of Dr. Chevalier Jackson, who has referred repeatedly to its presence, and has, I am sure, taught very many laryngologists besides myself of its existence and importance. I beg to apologize to Dr. Jackson for apparent tacit agreement with the name, but I have only recently noticed the error, and take this first opportunity of correcting it.—I am, etc.,

London, W.1, May 5th.

V. E. NEGUS.

#### STREPTOCOCCI AND PUERPERAL SEPSIS.

##### Apology and Correction.

We must apologize to Mr. J. T. Ainslie Walker for a blunder, for which our printing office is responsible, which occurred in the short communication by him published under this heading in the *Journal* of May 5th (p. 788). In the concluding sentence of his quotation the phrase "a pure culture of *S. p. aureus*" was printed as "a pure culture of *S. pallida aureus*." We hasten to correct this grammatical and bacteriological monstrosity and to express our sincere regret to Mr. Ainslie Walker.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week considered bills for transferring the currency note issue to the Bank of England, with consequent legal changes in Northern Ireland, and has also debated the Estimates for the Ministry of Health and the Ministry of Education. (Owing to the space occupied by the reports of the Harvey Tercentenary and the Conference on Rheumatic Diseases, the report of the debate on the Ministry of Health Estimates is unavoidably held over.)

#### National Health Insurance Bill.

The National Health Insurance Bill was again before a standing committee of the House of Commons on May 10th, when the committee completed its consideration of the bill. Discussion was resumed on the schedule of proposed additional benefits to be substituted for the third schedule of the National Health Insurance Act.

Mr. NAYLOR proposed to add payments in respect of deceased members as an optional benefit. He suggested that some approved societies could provide a funeral benefit of £3 or even more.

Mr. CHAMBERLAIN said the amendment raised a controversy which had been decided in the original Insurance Act. The addition of funeral benefit would be at the expense of other benefits, and would be paying empty honour to the dead at the expense of the living.

The amendment was rejected.

Dr. FREMANTLE proposed to add as an optional benefit "the payment of the whole or any part of the cost of medical or surgical advice or treatment by any registered medical practitioner, not being advice or treatment within the scope of any other additional benefit or of medical benefit, under a special scheme approved by the Minister for the purpose." He said this amendment had been approved at a meeting of the Parliamentary Medical Committee, and represented the general opinion of the medical profession, who wished to extend the Insurance Act by degrees. The amendment would cover surgical advice or operations by surgeons who could not permanently be retained as part of the panel system. It would cover skilled consultation, which would prevent sickness and aid panel practitioners, and would also include special treatment, such as the x-ray diagnosis for which Dr. Vernon Davies had asked. Doctors rather objected to the fact that the first seven benefits in the schedule before the committee were really cash benefits. They looked on the insurance scheme as one for prevention and treatment, cash benefits being only secondary.

Dr. DRUMMOND SMITH, in supporting the amendment, said the Royal Commission on Health Insurance had recommended it as the first change necessary to provide an adequate service. The national health scheme was at present incomplete, leaving out the services of the specialist who might by early intervention prevent serious ill health. The health side of the scheme had not been emphasized as it should be.

Mr. MELLER denied that the Royal Commission had recommended specialist service as an additional benefit. It had recommended an extension of the medical service as a statutory benefit when the money was available. As a result of the granting of additional benefits, insured persons who went to hospitals for treatment which could not be given by the panel practitioner were now met with the inquiry, "Is not your society providing dental treatment and ophthalmic treatment?" If the insured person said, "I believe so," help from the hospitals was cut off. If Dr. Fremantle's proposal were added to the additional benefits the medical profession would put more pressure on insured people to make their societies devote part of their surplus funds for this benefit, and incidentally for the benefit of medical practitioners.

Dr. DRUMMOND SMITH intervened to say the Royal Commission had both recommended this extended medical service as a statutory benefit and had shown that it could be provided within the present financial scheme. Dr. Shiels explained that as the approved societies had opposed that recommendation of the Royal Commission, he now commended Dr. Fremantle's amendment as a substitute.

Mr. RHYNS DAVIES said Dr. Fremantle had given the committee the impression that all money accruing to the insured population should be handed over to the medical profession. Dr. Fremantle should remember that when a man fell ill he lost his wages. If this amendment were adopted by an approved society a panel doctor might say to an insured patient, "The disease from which you are suffering is one which I cannot treat as a panel doctor. You must come to me as a specialist." Even now, in surgeries all over the country, doctors were saying to panel patients, "The service you ask is not the ordinary service mentioned by law." Under the amendment the panel doctor could say, "You must ask me for specialist treatment. I can get paid for that under this new provision." Of the sixteen additional benefits already allowed, not more than six had been adopted or would ever be adopted.

Mr. BRIANT thought it would be disastrous if a panel doctor were to pose as a specialist as well and extract additional fees.

Mr. RHYNS DAVIES: They do it now.

Mr. BRIANT said he feared that unless further provision were made for obtaining specialist opinion many lives would be endangered. The tendency was for the panel practitioner to continue his ordinary treatment, whereas well-to-do people had specialist advice at an earlier stage.

Mr. CHAMBERLAIN said Mr. Rhys Davies had argued that the provision of a specialist service would lead to the exploitation of the insured person by the practitioner. That argument would apply as much to the provision of the service as a statutory benefit as to its provision as an additional benefit. The Royal Commission had decided that the advantages for the insured population of recourse to specialists would outweigh all the disadvantages. Specialist service was only prevented from becoming a statutory benefit because the approved societies strongly objected to the method which the Royal Commission recommended for providing it. A panel doctor could not pose as a specialist and extract fees from his patients as such unless he satisfied his Insurance Committee that the particular complaint was beyond the competence of an ordinary general practitioner, and that he was competent as a specialist to treat it. The schedule already authorized an approved society to select, as an additional benefit, specialist treatment in an institution. The committee ought to give the society the chance of getting the same specialist service through private practitioners. He was disposed to advise the committee to accept the amendment.

Mr. BROAD said that a panel practitioner's 1,000 or 1,200 patients might be distributed between forty or fifty societies. For the practitioner to have to turn over the rules of all those societies to see whether he could refer a patient to a specialist would be inconvenient. When specialist advice came to be provided it should be in some way pooled so that there should be no pecuniary advantage in pushing people on to specialists.

The committee agreed to the amendment.

Dr. FREMANTLE then moved to add as a further alternative benefit: "The payment of the whole or part of the services of a midwife or medical practitioner in cases of confinement." He denied that he was putting forward proposals in the interests of the medical profession. Statutory maternity benefit was in cash, and was in many cases eaten up by other needs, so that proper provision was not made for the attendance of a midwife or a medical man. He asked that approved societies should be allowed, as some in rural areas now were allowed, to provide the services of the midwife in addition to the payment of the cash benefit.

Sir KINGSLEY WOOD said standard maternity benefit had been increased by many societies, and the average amount paid was about 46s. There had been a tendency from the first for the whole of the sum to be demanded by the doctor attending the confinement, and as the amount of maternity benefit had increased the doctor's fee had tended to increase *pari passu*. A subcommittee of the Consultative Council was considering the methods by which maternity was dealt with under national health insurance, and it was undesirable at present to include in the list of medical benefits the item proposed by Dr. Fremantle.

Dr. SNIELS said Sir Kingsley Wood had taken adroit advantage of the prejudice of certain Labour members against the medical profession. Local administration of an adequate maternity service was the best solution of this problem. Those who were studying the problem were directing their attention increasingly to that end.

The amendment was negatived.

Dr. FREMANTLE then moved that "medical treatment or attendance for any person dependent upon the labour of a member" should be an additional benefit. This was the first additional benefit in the third schedule of the Act of 1924, but had been omitted from the bill. Possibly it had not been adopted by any society; it was strongly opposed by a large section of the medical profession, and was not for the benefit of that profession.

Sir KINGSLEY WOOD said the Royal Commission had reported that the benefit had never been adopted by any society in England. Sir Walter Kinnear had reported that it was not suited for an additional benefit. Its cost would be greater than any individual society could provide as an additional benefit. Sir Kingsley contended that no society had adopted the benefit because it was impracticable. If adopted at all, it must be as a national scheme, and would cost a very large sum.

Dr. SNIELS said the purpose of the amendment would be served if it demonstrated that the scheme was not really a national health insurance scheme, that it left out the dependants of the insured person, and that it established unequal health standards in the community.

The amendment was rejected. Mr. WHITELEY moved, and Mr. CHAMBERLAIN resisted, an amendment to bring out-patient treatment within the scope of hospital benefit. This was also rejected.

Dr. YEANON DAVIES moved to add at the end of the schedule of additional benefits: "Payments to women in the last weeks of pregnancy who have had to leave their employment on account of that condition." He said he put down the amendment partly as propaganda, but also to give any up-to-date society the opportunity of paying those women who had to leave their work for natural reasons. It would have a definite effect on maternal mortality.

Mr. CHAMBERLAIN said the committee could not ask societies to pay benefits which would be subject to employers' caprice in fixing the number of weeks. If a real demand were discovered the list of benefits could always be increased under paragraph 16, even after the passage of the bill.

There was a tie on this amendment, 17 members of the committee voting for it and 17 against. The chairman, Sir Robert Sanders, gave his casting vote against the amendment and it was lost. The schedule of additional benefits was then added to the bill.

The second schedule proposed minor and consequential amendments in the principal Act of 1924. An amendment was made prolonging the free period of insurance given to an insured person ceasing from contribution if at the time of so ceasing that person was already ill. A new subsection was inserted providing for the control of the Seamen's Special Fund. Further discussion arose

regarding the qualification of share fishermen for national health insurance benefits. Mr. CHAMBERLAIN said the Acts had to be twisted and strained to bring them in at all. Such men when making preparations for the next voyage and repairing their nets should pay their own contributions.

The bill was then reported to the House, the CHAIRMAN remarking that the committee had been a model one.

#### Small-pox.

On May 11th Mr. CHAMBERLAIN told Mr. J. Hudson that he had received no report on the adequacy of the accommodation and staffing of the Whitehouse Farm Small-pox Isolation Hospital, Huddersfield. He had made no recommendation regarding the character of the present outbreak in the Huddersfield area, nor regarding the necessity of improving and extending the hospital provision. Diagnosis of the cases was a matter for the notifying medical practitioner, who could consult the medical officer of health in any doubtful case.

#### Investigation of New Discoveries in Connection with Disease.

Answering Sir Basil Peto, on May 10th, Mr. CHAMBERLAIN said the General Medical Council was not concerned with the investigation of new discoveries in connexion with, and of new treatments for, disease. The Medical Research Council was so concerned. Sir BASIL PETO further asked whether there was any body of medical men in this country whose business it was to make such investigation officially, and, if not, how the Ministry of Health was advised of new discoveries and treatments. Mr. CHAMBERLAIN replied that the recognized method of bringing a new discovery to notice was publication of the scientific evidence for it in a technical journal. This allowed its value to science or practice to be confirmed or otherwise by other workers.

Sir BASIL PETO asked how the public could be informed, in view of the action taken by the General Medical Council in the case of any member of the profession who advised the public of a new treatment by a communication in the public press.

Lady ASQUITH, intervening, asked whether Mr. Chamberlain did not think that the less the public knew, read, and thought about disease the freer they would be from it.

Mr. CHAMBERLAIN said he could not admit that alleged new discoveries should not be submitted to technical examination. It was impossible for the Medical Research Council to take useful action unless it had the advantage of such publication as he had suggested.

On May 10th Mr. CHAMBERLAIN told Sir Basil Peto that he had lately received from a medical specialist particulars respecting new discoveries in treatment for asthma and goitre. The case was not one where the Minister could appropriately take action.

Mr. CHAMBERLAIN, in an answer on May 10th to Mr. W. M. Adamson, said the Ministry of Health had laid down no special conditions in connexion with the appointment of the county medical officer for Salop, but he had suggested to the Salop County Council that it should have regard to the standard salaries for such appointments which had been commended by the Ministry for the guidance of local authorities. The county council had deferred consideration of the matter.

#### Foot-and-Mouth Disease.

Answering Sir Robert Thomas, on May 10th, Mr. GUINNESS said his attention had been drawn to recent experiments showing that the virus of yellow fever was alive after being frozen for twelve days. The proposal that imported chilled meat should be kept in store for thirty-one days as a quarantine precaution against foot-and-mouth disease would make the meat uneatable. Mr. GUINNESS added that there was a risk of foot-and-mouth disease being imported in frozen or chilled carcasses, but there was as yet no proof. Dr. VERNON DAVIES asked whether Mr. Guinness would insist on the carcasses being imported with the head and feet attached. Mr. GUINNESS said that would be an illusory safeguard. Animals might be infected without lesions on the head or feet. Replying to Mr. Haslam, Mr. Guinness said the Argentine Government had appointed seventy additional veterinary inspectors to inspect cattle before dispatch to the freezing stations for slaughter. The veterinary staffs at these stations had been strengthened to administer the new decree forbidding the export to Britain of the carcasses of animals infected with disease or of any which had been in contact with them. All parties were making a real attempt to carry out the new law.

*Closing of Ministry of Pensions Clinics.*—On May 15th Lieut.-Colonel G. F. STANLEY told Mr. Neil McLean that the clinics for ear, nose, throat, and eyes at the Adelphi Hotel, Glasgow, were closed in accordance with the advice of the Ministry of Pensions' responsible medical advisers when the number of patients had fallen to an extent that rendered the maintenance of separate clinics by the Ministry no longer justifiable. Suitable arrangements had been made for the treatment of any cases at the local civil hospitals in accordance with the normal practice of the Ministry. Mr. McLEAN asked whether the cases were now being treated at the same place, but by another doctor. Lieut.-Colonel STANLEY said that he was not aware of that. All he was concerned with was whether the Ministry was justified in keeping these clinics open when there was not sufficient work to keep them occupied. The information which he was sending to the hon. member would show that although the clinics had been closed, the work was being carried on in the same place. There were nine ophthalmic cases in the whole of Glasgow, and only four

anal cases. That was not a sufficient number to justify keeping the clinics open. As far as he knew there were no nose and throat cases.

**Medical Examination of Prospective Emigrants to Canada.**—Mr. AMERY, replying to Mr. Haslam, on May 14th, said that in the first four months of this year 30,451 persons were requested by the Canadian authorities to present themselves for medical examination with a view to their settlement in Canada. Of these, 29,203 were examined. The remainder would probably be examined during the coming months. The numbers rejected on medical grounds, or unable to attend for examination for reasons of distance, inconvenience, and expense, were not yet known. Mr. Haslam asked if Mr. Amery would get into touch with the Canadian authorities and use his influence to see that no able-bodied man or woman who might be desirable was excluded. Mr. AMERY said the Dominions Office was doing all it could.

**Sale of Food and Drugs Acts.**—On May 14th Sir KINGSLEY WOOD, in reply to Dr. Vernon Davies, said that the Sale of Food and Drugs Acts were administered by the health authorities of certain counties. In some counties the public health committee or the medical officer of health, or both, took part in the administration of the Acts. He could not state the number of such counties.

**Leprosy in Palestine.**—Mr. AMERY, replying to Sir R. Thomas, on May 14th, said that in February, 1926, it was estimated that there were fewer than eighty lepers in Palestine. The disease appeared to be dying out naturally. In 1927 the Moravian Leper Hospital at Jerusalem had on the average 28.75 in-patients, and twenty-four lepers received out-patient treatment at Government dispensaries. The High Commissioner was satisfied that sufficient facilities existed in Palestine for the treatment of leprosy.

**Health of Prisoners in the Solomon Islands.**—A report to Mr. Amery on the condition of the Solomon Islanders in prison awaiting trial states that up to March 8th five deaths had occurred—two from dysentery and three from causes other than dysentery. Many of the prisoners were under-nourished and emaciated when they were brought in, all were kept under close observation by the senior medical officer, and their general health improved as a result of a regular and substantial diet. Apart from the outbreak of dysentery there had been little illness among the prisoners.

**Duties of Registrar of Deaths.**—Sir KINGSLEY WOOD, replying to Mr. Kelly, on May 15th, said that it was not the duty of the registrar of deaths to ask questions in cases where the cause of death was certified by the medical practitioner who attended the deceased person. Where the cause of death was not so certified, the registrar was required to refer the case to the coroner, and only to enter the cause of death according to information elicited by himself in cases where the coroner had deemed an inquest unnecessary. Even where the cause of death was medically certified, it was the duty of the registrar to refer the case to the coroner if he had information that death might have been due to causes falling within certain categories laid down by regulation. These categories included cases where death appeared to have been due to starvation or privation.

#### Notes in Brief.

Excluding lunatics in county and borough asylums, persons in receipt of domiciliary medical relief only, and casuals, totalling about 127,000, the greatest number of persons in receipt of Poor Law relief in England and Wales on any Saturday in the winter of 1927-28 was 1,255,251, on January 7th, 1928.

In 1927 the number of children in the London area who attended open-air classes was 1,680.

In the year ended March 31st, 1928, 202,930 widows' pensions and 15,560 orphans' pensions were granted in England and Wales. Included with the widows' pensions were 257,500 children's allowances.

Mr. Chamberlain has decided that houses completed by March 31st, 1929, shall, if otherwise eligible, qualify for subsidy at the existing rates.

### Medico-Legal.

#### £1,000 DAMAGES FOR A MEDICAL MAN.

A JURY at Leeds Assizes, on May 8th, awarded £1,000 damages to Dr. W. S. Henderson, medical officer to Sedburgh School, for the following libellous passage contained in a letter written by the father of a schoolboy to the headmaster of the school: "In my opinion his callousness and ignorance prove him to be quite unsuitable for the responsible position which he holds."

Dr. Henderson commenced his duties at Sedburgh School in October, 1926. In the following October one of the boys, Donald Ackerley, contracted scarlet fever and came under his care. Dr. Henderson treated the boy until he was sent home on December 14th, 1927, and on December 16th the father, Mr. R. C. Ackerley, wrote to the headmaster that two doctors had examined the boy and had diagnosed inflammation of the hip-joint. The letter continued: "It is by no means an uncommon complication arising from scarlet fever, so this makes Dr. Henderson's case worse than I thought." Then followed the words complained of. Counsel for the plaintiff added that upon the issue of the writ in the action the school

authority, taking the view that they could not have their dirty linen washed in public, called upon Dr. Henderson to resign.

Dr. Henderson, giving evidence, said that the boy had sometimes complained of pains in his hips, thigh, knees, and chest, and he considered they were due to muscular rheumatism, a symptom sometimes found in cases of scarlet fever. Dr. Maxwell Telling, professor of medicine at Leeds University, told the jury that he would have made exactly the same diagnosis and advised the same treatment as had Dr. Henderson.

The defence was a plea that the letter was written on a privileged occasion, and a denial that it bore the meaning the plaintiff alleged, but there was no plea of justification. A father's letter to a headmaster is written on a privileged occasion, but it is only a qualified privilege, which is lost on proof of malice, and the question whether or not the writer was actuated by malice is one for a jury to decide. Here, as Mr. Mortimer, K.C., for the plaintiff, said, not only had the defendant abused the privilege by going further than he ought to have gone, but he had not even sought to justify the allegations he had made, nor shown any sign of repentance.

Great sympathy for both sides was expressed by Mr. Justice Talbot in his summing-up to the jury. His Lordship pointed out that the evidence had demonstrated that there was no error in treatment, with a possible exception regarding a rise in the boy's temperature on his last day in the school infirmary.

The solicitors for the plaintiff were Messrs. Le Brasseur and Oakley, instructed by the London and Counties Medical Protection Society.

### Universities and Colleges.

#### UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 12th the following medical degrees were conferred:

M.D.—J. P. W. Jamie, H. Galsborough.  
B.Clin.—J. J. Panting.

#### UNIVERSITY OF LONDON.

##### Recent Developments in Medical Education.

THE report of the Principal Officer on the work of the University of London during the year 1927-28 records a number of developments of some medical interest. Reference has already been made to the purchase of the Bloomsbury site, which was made possible by a very large contribution from the Rockefeller Foundation. That institution has also given £25,000 for the endowment of the department of pharmacology, and £50,000 for the endowment of the departments of anatomy and physiology, all at University College. Further large benefactions have been made to provide for the establishment of a chair of dietetics, which will be at first a part-time appointment and which, it is hoped, will be attached to the St. Thomas's Hospital Medical School. Regarding the medical education of women undergraduates the report refers to the appointment, by the Senate, of a committee to consider the question, and states that much of the preliminary work of inquiry has already been done. In the course of the past year academic diplomas in bacteriology and in biology have been instituted. The trust deed providing for the Geoffrey E. Duveen Lectureship in Otolaryngology has been varied to allow the establishment of a travelling post-graduate studentship in oto-rhino-laryngology and of a fund for the promotion of research in that subject.

Changes among the medical and associated teaching staffs have been numerous. At King's College Miss D. L. Mackinnon has succeeded Professor J. S. Huxley in the chair of zoology, and Mr. D. MacC. Blair has been appointed professor of anatomy in succession to Professor E. Barclay-Smith. In the medical schools Sir Frederick Andrews has retired from the St. Bartholomew's staff, and Professor E. H. Kettle is the first holder of a new University chair of pathology. The new readership in this subject is held at the Westminster Hospital Medical School by Dr. J. A. Braxton Hicks. Readerships in morbid anatomy and histology and in bacteriology have been instituted at the Middlesex Hospital and University College Hospital respectively. Three chairs have been added to the establishment of the London School of Hygiene and Tropical Medicine: Dr. W. W. Jameson has been appointed professor of public health, Mr. M. E. Delafield professor of chemistry as applied to hygiene, and the chair of biochemistry remains to be filled. Dr. G. S. Wilson becomes reader in bacteriology and immunology. At the School of Pharmacy the first holder of the readership in pharmaceutical chemistry is Dr. W. H. Linnell.

#### LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD.

##### Medical Scholarships.

THE London Inter-collegiate Scholarships Board announces that an examination for six medical scholarships and exhibitions, of an aggregate total value of £513, will commence on June 26th. They are tenable at University College Hospital Medical School, the London (Royal Free Hospital) School of Medicine for Women, and the London Hospital Medical College. Full particulars and entry forms may be obtained from the secretary of the Board, Mr. S. C. Ranner, M.A., the Medical School, King's College Hospital, Denmark Hill, S.E.5.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ORDINARY Council meeting was held on May 10th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

## Fellowships.

Mr. C. Thurstan Holland and Lieut.-General Sir Matthew H. Gregson Fell, K.C.B., C.M.G., were admitted Fellows of the College.

## John Hunter Medal.

Mr. Victor E. Negus was presented with the John Hunter Medal in bronze and a cheque for £50 for his investigations into the comparative anatomy and physiology of the larynx and the anatomy of the bronchi in their relation to surgery.

## Membership and Diplomas.

Diplomas of membership were granted to 152 candidates whose names were among those noted as granted licences to practise by the Royal College of Physicians in the list published on May 5th (p. 786). Diplomas in public health were granted jointly with the Royal College of Physicians to 18 candidates.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS  
OF GLASGOW.

At the monthly meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on May 7th, George Henry Edington, M.D., D.Sc., was appointed as the representative of the Faculty upon the General Medical Council.

## The Services.

## TERRITORIAL DECORATION.

THE KING has conferred the Territorial Decoration upon the following officers of the Royal Army Medical Corps, T.F.: Hon. Colonel A. Thorne, V.D., Majors N. M. Ferguson, J. F. Edmiston, T. W. S. Hails, J. A. Stenhouse, and F. H. White.

## NAVAL MEDICAL COMPASSIONATE FUND.

THE quarterly meeting of the directors of the Naval Medical Compassionate Fund was held on April 26th, when Surgeon Vice-Admiral Arthur Gaskell, Medical Director-General of the Navy, took the chair, and the sum of £175 was distributed among the several applicants.

## Obituary.

WE regret to announce the death, at the age of 92, of Dr. HENRY JAMES ALFORD, which occurred at his home in Taunton on April 17th. He belonged to a well-known Somerset family, and his father, who also lived until over 90, preceded him in medical practice at Taunton, while one of his brothers was a surgeon. Dr. Alford received his medical education at University College, London; he obtained the diplomas M.R.C.S.Eng. and L.S.A. in 1858, graduated M.B. in 1861, and proceeded M.D.Lond. in 1872. After spending some years in practice with his father he was, in 1873, appointed medical officer to the old Taunton Board of Health. Four years later, on the incorporation of the borough, the new council came into existence, and he retained the office of medical officer of health to that body, continuing in this capacity until his retirement after forty-six years of service in 1919, when he had reached the age of 83. He remained in service in a consultative capacity to the time of his death. He was for a considerable period consulting physician to the Taunton and Somerset Hospital. Until a few months ago he remained in good health. His devotion to his office and to the affairs of his native town monopolized the greater part of his time and energy, but in his youth Dr. Alford gained some fame as an amateur actor, and throughout his life took a keen interest in local dramatic and musical works. Many years ago he was received into the Roman Catholic communion, and he was a devout member of that Church. The interment in St. Mary's Cemetery was preceded by a requiem service at St. George's Church, Taunton, conducted by the Very Rev. Canon Iles, and attended by the mayor, members and officials of the corporation, representatives of the medical profession and of the religious communities with which Dr. Alford was associated.

Dr. MATTHEW CURSHAM CORNER, who died on April 25th, in his sixty-ninth year, at his residence in Mile End, had throughout his life been identified with work in the East End of London. The son of a medical practitioner, he

received his professional education at the London Hospital, and in 1882 obtained the L.S.A. After serving as clinical assistant at the East London Hospital for Women and Children he took over his father's practice in the Mile End district, where he remained until his death. For forty-two years he was medical officer and lecturer to the East End Mothers' Lying-in Home, the institution in connexion with which he was, perhaps, best known, and to which he was latterly consulting physician. He was also for many years visiting or resident medical officer to the Tower Hamlets Dispensary, and had at one time or another been associated with the Royal Maternity Society, the East London Nursing Society, the Whitechapel Dispensary, the Trinity Almshouses, and the East End Emigration Society. He was honorary medical officer to the National Children's Adoption Association, and honorary consultant to the Stepney School for Mothers. Dr. Corner participated actively in professional affairs, and was a past-president of the North-East London Clinical Society. In the British Medical Association he had served as a member of the Metropolitan Counties Branch Council and as chairman, from 1922-26, of the Tower Hamlets Division. He was a justicer of the peace, and had served as chairman of the Mile End Petty Sessions and as a member of the Shore-ditch Children's Criminal Court. Among his publications may be noted one, entitled *A Defence of East London*, which gives the clue to his main interest in life—the welfare of that district where he was particularly devoted to any service designed to help its mothers and its children.

Dr. JOSEPH HORNS FENN, who died on May 3rd at Rusthall, Tunbridge Wells, at the age of 60, was the third son of the late Mr. Albert R. Fenn of Madrid. He received his medical education at the London Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1897. Dr. Fenn soon afterwards went to Mexico, where he became well known as a surgeon in mining centres and travelled extensively. During the war he held a commission as captain in the R.A.M.C., serving first on troopships to and from the Mediterranean and Australian ports. He was later transferred to the Royal Herbert Hospital at Woolwich, and then to the Military Hospital at Hounslow; as he had made a special study of tropical diseases he was subsequently appointed medical officer in charge of the Gravesend Military Hospital. After the war, and until incapacitated by a long illness, Dr. Fenn held an appointment under the Ministry of Pensions in the tropical diseases department. He retired four years ago to Rusthall, Tunbridge Wells, where he patiently bore the increasing limitations and sufferings following upon encephalitis lethargica. His death is much regretted by his many colleagues and friends. He was a member of the British Medical Association.

## Medical News.

THE annual oration to the St. John's Hospital Dermatological Society will be given at 5.30 p.m. on Wednesday May 23rd, at St. John's Hospital, Leicester Square, by Sir John Bland-Sutton, Bt., whose subject will be "The debt of dermatology to optical glass." On the same evening, at 7 o'clock, the annual dinner will be held at the Café Royal. Fellows intending to be present are asked to notify the honorary secretary of the society at 49, Leicester Square, W.C.2, not later than Tuesday, May 22nd.

Dr. JANE WALKER will open a discussion by the North-Western Tuberculosis Society on tuberculosis and employment at the Tuberculosis Offices, Joddrell Street, Hardman Street, Manchester, on Thursday, May 24th, at 3 o'clock. All medical practitioners interested are cordially invited to attend.

THE twenty-ninth annual meeting of the Lebanon Hospital for Mental Diseases, which is situated at Asfurieh, near Beirut, in Syria, will be held at Friends' House, Euston Road, N.W., at 3 p.m., on Tuesday, May 22nd. Sir Wyndham Deedes, late Chief Secretary to the Palestine Government, will preside, and a short address on "The importance of treating early mental disorder" will be given by Sir Maurice Craig. Sir Robert Armstrong-Jones and Dr. Bedford Pierce

will also speak. The Lebanon Hospital is the only institution of its kind in Syria, and provides training facilities for medical students at Beirut University. Its administration is on an international basis, with headquarters in London and associated committees in Holland, Switzerland, and America. Readers who are interested and who desire to attend the annual meeting may obtain particulars from the London office, 139, Marylebone Road, W.1.

THE opening ceremony in connexion with the Princess of Wales Dispensary for Children will be performed by the Queen, at 3.30 p.m., on Friday, May 18th. The hospital had its origin in a small dispensary started by a few medical practitioners in Church Street, Kensington, in 1840; in 1896 a small ward was added and the institution took the name of the Kensington Dispensary and Children's Hospital. Four years ago it became clear that a greater need existed for the hospital in North Kensington, then in its original situation, and that it would require a very considerable extension to provide the desired facilities. Under the patronage of H.R.H. Princess Louise, Duchess of Argyll—and largely at her instigation—a scheme was inaugurated which has resulted in the creation of the new hospital situated at St. Quintin Avenue, North Kensington, W.10. The first building scheme, comprising the out-patient department and one ward block, was started in November, 1926, and last summer the board decided to proceed with the second ward block. Out-patient work in the new hospital commenced in December, 1927, and the first in-patients were admitted soon after.

THE annual meeting of King Edward's Hospital Fund for London was held at St. James's Palace on May 15th, the Prince of Wales presiding. In his address he stated that £1,800,000 a year is now voluntarily subscribed to London hospitals. The Fund last year distributed £247,000, while, in addition, special grants from the legacies left by the late Mr. and Mrs. John Wells of St. Albans had been distributed since 1924, the total of £255,000 having helped to provide 1,600 additional beds. The Prince of Wales said there were now in London 900 "pay beds" for the professional and middle classes, and that the report of the committee appointed to inquire into the question of this class of hospital accommodation was in course of preparation. A fuller account of the proceedings of the meeting will be given next week.

THE summer session of the South-West London Post-Graduate Association opened on May 16th, and a lecture-demonstration will be given each week until July 12th. Two outings are included in the programme, these taking the form of visits to the King Edward VII Sanatorium, Midsbury, on June 12th, and to the Cassel Hospital for Functional Nervous Disorders, Penshurst, on June 27th. Full information may be obtained from the honorary secretary, Dr. R. J. Saunders, 10, Lyford Road, Wandsworth Common, S.W. 18.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Friday, May 25th, there will be two demonstrations: the first, in gynaecology, by Mr. A. C. McAllister, at 10 a.m., at the Royal Waterloo Hospital, and the second, of the fundus oculi, by Mr. Lindsay Rea at 8.30 p.m., at the in-patient department of the West End Hospital for Nervous Diseases, Gloucester Gate, Regent's Park. Intending visitors to Mr. Lindsay Rea's demonstration are asked to apply first to the Fellowship of Medicine (Mayfair 2236). Special courses in June are as follows: June 4th to 16th, diseases of children; June 18th to 30th, chest diseases at the Victoria Park Hospital and gynaecology at the Chelsea Hospital for Women; June 25th to July 21st, neurology at the West End Hospital for Nervous Diseases, starting at 5 p.m. daily; and a course in medicine, surgery, and the specialties at the London Temperance Hospital. This last-named course is primarily intended for practitioners who have little spare time, and it has been arranged to take place in the late afternoons from 4.30 to 6 o'clock. Full particulars and copies of all special-course syllabuses are obtainable from the Fellowship of Medicine, 1, Wimpole Street, together with information on the general course of work.

THE house and library of the Royal Society of Medicine will be closed on Saturday, May 26th, and Monday, May 28th.

DR. E. GRAHAM LITTLE, M.P., has been elected an honorary member of the Norwegian Medical Society.

THE annual general business meeting of the National Incorporated Association of Dr. Barnardo's Homes was held on May 9th. The annual report showed that new admissions in 1927 totalled 2,025, of which 1,648 were permanent and 377 temporary. The average number of children in residence throughout the year in the cottages, households, and branches of the institution throughout the country was 7,716; of these children, 1,203 were under 5 years old and 422 were crippled, blind, deaf and dumb, or otherwise afflicted. The income for the year from all sources was £521,514 and the expenditure was £521,499.

TOWARDS the sum of £40,000 required for the establishment in London of a clinic for the treatment of rheumatic diseases £23,153 had been received by the British Red Cross Society up to the end of April. It is expected that the work of adapting and equipping the building chosen for the clinic will be begun shortly. A treatment fund has been opened at the instance of friendly societies and approved societies. The St. Marylebone Division of the British Red Cross has made a donation of £50 towards a Samaritan fund to assist those who cannot pay the full fees.

THE Treasury has made an order under Section 10 of the Finance Act, 1926, exempting radium compounds from Key Industry Duty from May 15th to December 31st, 1928. This step has apparently followed representations from certain hospitals to the Chancellor of the Exchequer. The imposition of the duty has been attacked as the cause of difficulty in securing supplies of radium salts, notably for the treatment of cancer. Very small amounts of radium are produced in Great Britain, and the world's supplies are obtained for the most part from the Belgian Congo.

THE annual medical cruise organized by the *Bruxelles-Médical* will start from Bordeaux on the mail steamer *Brazza* on July 29th. Visits will be paid to Corunna, Vigo, Oporto, Madeira, Tenerife, Las Palmas, and Ajaccio. The prices range from £45 10s. inclusive upwards. Further information can be obtained from the Section des Voyages de *Bruxelles-Médical*, 29 Boulevard Adolphe Max, Brussels.

AN international congress of open-air schools will be held in Paris from July 8th to 12th, under the presidency of M. Paul Strauss, with Professor Nobécourt as president of the Medical Section and Dr. Lesage as general secretary. Great Britain will be represented by Miss M. MacMillan. Further information can be obtained from M. Lemonnier, 37, Avenue Victor-Emmanuel, Paris.

A BILL to direct that the principal civil medical officer shall in future be known as and styled the director of medical and sanitary services has been passed by the Legislative Council of Hong-Kong. The change of title is being made in connexion with the reorganization of the medical and sanitary departments.

WITH a view to assisting German scientists in research an effort is being made by a German society to supply the universities and students of that country with medical and scientific literature of the war period and subsequently. Copies of the *British Medical Journal* and the *Lancet* for the years 1914 to 1924 are particularly required, single numbers being welcomed if complete sets cannot be obtained. Those who are willing to assist in this are invited to notify the *Notgemeinschaft der Deutschen Wissenschaft*, Berlin C.2, Schloss Portal 3. Expenses incurred in sending books and journals will be refunded.

THE health section of the League of Nations Health Organization has issued a pamphlet containing a list of its publications down to March this year. The booklet serves as an index to the activities of this body, and research workers and others will find it useful as a bibliography of the many routine reports and special studies undertaken by its Commissions. Brief details are given of the scope of each publication.

THE late Professor Gilbert has bequeathed a series of medico-historical collections to the history of medicine museum of the Paris faculty of medicine, with a sum of 40,000 francs for their instalment.

THE international congress of applied psychology will meet at the Palais-Royal, Paris, next October.

THE sixth international congress for combating tuberculosis will be held in Rome from September 24th to 28th, under the patronage of the Italian Government and the presidency of Professor Raffaele Paolucci of Rome, with Professor Léon Bernard as general secretary. Papers will be read by Professor Calmette on the filterable elements of the tuberculous virus, by Professor R. Jemma of Naples on the diagnosis of infantile tuberculosis, by Professor Morelli of Pavia on the pneumothorax treatment of pulmonary tuberculosis, by Dr. William Brand of London on the organization of antituberculous prophylaxis in rural districts, and by Professor L. Bräuer of Hamburg on the surgical treatment of pulmonary tuberculosis. The subscription for the congress is 100 lire, which is payable to the *Federazione Nazionale Italiana Fascista per la lotta contro la tubercolosi*, 12 Via Toscana, Rome. An exhibition of methods for dealing with tuberculosis will be held during the congress, which will be followed by excursions to Italian sanatoriums.

THE second quarterly issue of *Seuchenbekämpfung*, the Viennese journal dealing with the etiology, prophylaxis, and experimental treatment of infectious diseases in man and animals, is dedicated to Professor Richard Pfeiffer of Breslau, the discoverer of the influenza bacillus, on the occasion of his seventieth birthday.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the British Medical Journal must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the Journal, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the British Medical Journal are MUSEUM 9361, 9362, 9363, and 9364 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Medisecra Westcent, London.

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Racillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

### QUERIES AND ANSWERS.

"COWAL" asks where he can find the best description of, or treatise on, orthodiagraphy of the heart and radioscopy of the chest and abdomen. He requires such an account as would appeal to the general physician with a special leaning towards cardiology.

#### HARDENING THE FEET.

DR. W. S. SODEN (Winchcombe) writes in reply to "H. R." (May 5th, p. 787): Soaking the feet in a 1 per cent. aqueous solution of picric acid hardens the skin well. A friend of mine always did this with a battalion in Sinai during the war with excellent results.

#### VITAGLASS.

DR. W. COLQUHOUN (Dunmurry, co. Antrim) asks whether there is any evidence for the assertion that vitaglass, after being subjected to the sun's rays for some time, becomes discoloured and impermeable to the ultra-violet rays.

#### INCOME TAX.

##### Purchase of Practice.

"H. K." bought a practice with a three months' introduction on equal sharing terms as from April 1st, 1928, and is taking a partner as from July 1st, 1928, on a three-fifths and two-fifths basis. How should his liability be assessed?

\* \* The gross assessment should be based on the amount of his predecessor's earnings for the previous year. This amount will be divisible thus:

Former proprietor 1/2 of 1/4...	...	...	=1/8.
Sell 1/2 of 1/4 + 3/5 of 3/4	...	...	=23/40.
Incoming partner 2/5 of 3/4	...	...	=3/10.

The appropriate personal allowances will, of course, be deductible from the respective shares. If the profits of the practice for 1928-29 should fall short of the profits for 1927-28 from some specific cause then "H. K." and his partner can claim an adjustment when the former amount is ascertained.

##### Motor Car Transactions.

"J. W. C." bought a car in June, 1924, for £300 and sold it in March, 1928, for £60, buying a car of a different make for £385. He claimed depreciation £40 for 1926-27 and £30 for 1927-28.

\* \* He can claim "obsolescence," but not "renewals," and also depreciation. The obsolescence claim should be for £300-£60-(£40+£30)=£170. (We are assuming that the depreciation was allowed, if it was not allowed the claim should be for £300-£60=£240.) The depreciation claim will be on £385 at 15 or 20 per cent.

"W. J." bought a car in 1922 for £863 and sold it in 1926 for £150, when he bought another for £1,922. He had another car, which he bought in 1914 for £688 and sold in 1927 for £20, buying in replacement another car for £319. What allowances can he claim?

\* \* Obsolescence allowance (1) as an expense of the year 1926, £863-£150=£713; (2) as an expense of the year 1927, £319-£20=£299. Depreciation allowance for the financial year 1927-28, £1,922 at 15 per cent.=£288, and for 1928-29 (£1,922-£288=) £1,634+£319—that is, £1,953 at 15 per cent., £293. It should, however, be stated with regard to the obsolescence allowance that in the circumstances the title thereto is not beyond dispute for years as for which depreciation is also claimed, and the claim for 1926 may be out of date.

### Depreciation on Car.

"RUSTICANUS" makes his accounts up to July 31st; he bought a new car on March 29th, 1928, and has claimed depreciation allowance for 1928-29 on the value of that car. The inspector of taxes, however, considers that the allowance should be made on the basis of the value of the car used at July 31st, 1927.

\* \* The course proposed by the inspector is the usual one and has been judiciously approved. In this case, however, there are some grounds for the view taken by our correspondent—for example, the unusual length of time elapsing between the close of his account and the commencement of the year for which the allowance is made. In the long run the difference should disappear, and the point is, perhaps, hardly worth pressing. One means of avoiding the result that has been reached would be to make the next professional account for the eight months to March 31st, 1928, and apply for the 1928-29 assessment to be made not on the agreed figures, but on the amount of the profit for those eight months plus one-third of the profits for the previous twelve months. On that basis the new car would automatically come into the depreciation calculation for 1928-29.

### LETTERS, NOTES, ETC.

#### THIRTY YEARS' SURVIVAL AFTER EXCISION OF TONGUE.

MR. J. MACKWEN (Glasgow) writes: The following extract from a letter sent me by Dr. J. Robson Turner, Paisley, is self-explanatory, and may prove of interest to some of your readers.

A patient told me he had been at the funeral of R. F., aged 81, who had an operation at your father's (Sir William Mackewen) hands for cancer of the tongue, thirty years ago. I thought the story so remarkable in the success of the operation, and the longevity of the patient, that I ought to draw your attention to it.

The man referred to by Dr. Turner had an excision of the whole tongue, together with the glands in the neck, performed as stated. He was said to have been of a silent disposition prior to operation, but he became very loquacious after it, and was ever ready to give the students examples of his powers of speech. It was generally believed in those days that removal of the tongue rendered the victim mute, and this patient's performance accordingly created much surprise. In those days likewise the phonograph was a comparatively recent and marvellous invention, and Dr. John Macintyre of Bath Street, Glasgow, took a record of this man's speech on a wax cylinder, using a recording needle, and, later, let my father and a visiting American surgeon friend hear the result over the telephone, which, likewise, was still something of a novelty.

#### SOME OLD MEDICAL BOOKS.

THERE were a few notable old medical books in Messrs. Hodgson's sale at their Chancery Lane rooms on May 16th, 17th, and 18th. Foremost in point of interest, perhaps, was a first edition of

Peter Lowe's "The Whole Course of briefly set downe the Cause, Signes, Curations of all sorts of Tumors, Wor- Dislocations and all other Diseases usually practised by Chirurgeons, according to the opinion of all our ancient Doctors in Chirurgerie," published by T. Purfoot in 1597. This book is not recorded in the Short Title Catalogue, so it must be extremely rare. There was also a copy of the "Regimen Sanitatis Salerni," the English translation by Thomas Paynell, published in 1575; and another of the sixteenth century, probably earlier than the foregoing, was the "Practica Geraldii de Solo super uno Almansoris." Of the seventeenth century may be noted a late edition (1626) of Thomas Vicary's "English-man's Treasure, with the true Anatomie of Man's Body, wherunto are annexed many secrets appertaining to Chyrurgerie"; W. Bale's "Briefe Treatise touching the Preservation of the Eyesight" (1654); "A Short Treatise showing the causes and remedies of that General Disease... termed by many the Plague of the Guts; but it is very probable to be the Dysenteria, or Red Flux," by N. H. (1658); "Fons Salmis, or the Fountain of Health Opened," by T. Monison (1665); and one or two others of minor interest.

#### SEA-SICKNESS AND TRAIN-SICKNESS.

"M.D." writes: To those who are prone to suffer from *mal de voyage*, whether in trains, steamers, or in motor cars, there is one simple precaution which I can recommend—namely, that for several hours before and during their travel they should avoid partaking of tea and eggs. Several people by doing so have been able to undergo in comfort and even with enjoyment journeys which, taken after a meal containing either tea or eggs, and, worst of all, both, have produced severe nausea and sickness. I hope this information may enable many others to enjoy journeys which in the past have been only painful necessities to be endured.

#### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 52, 53, 54, 55, 58, 59, and 60 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenancies at pages 56 and 57.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 219.

# PULMONARY ASBESTOSIS IN SOUTH AFRICA.

(With Special Plate.)

BY

F. W. SIMSON, M.B., CH.B.ED.,

PATHOLOGIST AT THE SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH,  
JONANNESBURG.

It has been known for some time that workers exposed to the dusty atmosphere arising from some processes involved in the preparation of asbestos materials suffer from pulmonary disability. The mining of the mineral itself is probably not a source of danger, as asbestos is mined mostly in open quarries. After sorting, there remains waste rock which still contains fibre in payable quantity. Crushing of this rock causes a considerable degree of dust exposure, and exposure to the dusty atmosphere is still more exaggerated in the carding and spinning of asbestos in the mills.

Very little concerning the pathological changes in the lungs of persons working with asbestos has been found in the literature, and it was thought that a record of the following cases might be of interest.

On September 2nd, 1926, the medical officer of an asbestos mine in Southern Rhodesia forwarded to the South African Institute for Medical Research three small specimens of lung from a *post-mortem* case for histological examination.

## CASE I (No. 9026).

The subject was a male adult native, who had worked for twelve months in the asbestos mill, and, except for a short period before his death, had had a good record of health. For nine weeks before death he suffered from acute tuberculosis, and the *post-mortem* findings showed miliary tuberculosis involving the lungs, liver, spleen, and pericardium. The object of the histological examination was to ascertain if there was any evidence of fibrosis in the lungs which might be directly ascribed to the nature of his employment, since workers in the mill are exposed to a very dusty atmosphere.

Apart from the tuberculosis and associated fibrosis, sections of the lungs showed a certain amount of connective tissue change which had no obvious connexion with the tuberculous process. It was also found that curious golden yellow segmented structures, with rounded or club-shaped ends (Fig. 1), were embedded in this fibrous tissue, together with very minute, doubly refractile particles, the latter presumably silica. Although the curious segmented bodies were remarked upon, no further investigation was carried out at the time, and the new-formed fibrous tissue was attributed to the presence of silica.

## CASE II (No. 11016).

It was not until September 29th, 1927, when a portion of lung from a second case was sent by the medical officer from the same mill, that the foreign bodies and fibrosis were more fully investigated. This piece of lung was from a male adult native who had been employed in the mill for a period of two years. About September, 1926, he was admitted to hospital suffering from pneumonia, and had a long illness. He was discharged, and later (September 19th, 1927) readmitted in a dying condition. He was very emaciated, and had the physical signs of pulmonary tuberculosis with fibrosis. At autopsy the lungs were firmly bound down by adhesions, the root glands enlarged and hard, and the lungs on section hard and fibrous with an almost leather-like consistence. The mesenteric glands were also considerably enlarged.

Histological sections showed a generalized but moderate degree of fibrous thickening of the pleura, trabeculae, and alveolar walls. In addition, there was a much more marked fibrosis arranged in irregular-shaped nodules, chiefly related to the blood vascular system and bronchi. This fibrous tissue was cellular, the elements arranged in an irregular manner, and included some small lymphocytic accumulations (Fig. 2). There was no resemblance to the orderly, whorled arrangement and sharp definition of the silicotic nodule (Fig. 3). The bronchi were the seat of slight catarrhal changes, and many of the alveoli contained "dust cells" filled with phagocytized particles. There was no evidence of tuberculosis or acute pneumonic consolidation. Embedded in the fibrous tissues, lying free in alveoli (Fig. 4), and contained in phagocytic cells, there were numerous golden yellow segmented bodies (Figs. 5 and 6), a few large angular black bodies, and very minute doubly refracting particles. Phagocytosis was a very striking feature. Large numbers of the bodies were contained within ordinary mononuclear cells and irregular-shaped multinucleated giant cells

(Fig. 7). Phagocytosis was not confined to the smaller particles, but even large rods were seen completely enclosed and often bent in order to allow them to occupy the space within the cells (Fig. 7). It was thought that these foreign bodies, together with the crystalline matter, may have been the cause of the fibrosis, as the connective tissue, both in distribution and formation, was very suggestive of changes resulting from a dust occupation of the lungs. At the same time the history of pneumonia and protracted recovery must be taken into consideration, since an unresolved pneumonia with subsequent fibrosis is not an uncommon occurrence amongst natives working on the mines in South Africa.

## CASES III AND IV (Nos. 6419 and 6731).

Consultation of the records and previous histological sections of material from the same mine has revealed two additional cases, both of which showed lobar pneumonia. There was very little connective tissue increase, but the unusual structures (Fig. 8) and refractile crystalline particles were present. No history of length of service in the mill was obtained with either of these cases.

Further study of the golden yellow bodies showed a variety of shapes, but the most common forms had rounded or club-shaped ends and a segmented body tapering to a finely pointed tail. They were non-refractile to polarized light, soluble in strong acids, and, on raising to a red heat, turned black and tended to lose their outline. In sections treated with hot dilute hydrochloric acid and potassium ferrocyanide they gave a well-marked Prussian blue reaction. No pigment except these structures giving the iron reaction could be detected in the sections examined. Strong hydrochloric acid, having been tested for the presence of iron and found negative, was used to dissolve out iron from fresh sections. After treating the sections the hydrochloric acid gave a very distinct red-pink colour with potassium thiocyanate, and the red-pink colour disappeared on the addition of a solution of mercuric chloride. The sections were re-examined and showed that the majority of the golden yellow bodies had been dissolved out. From these tests it was concluded that the structures contained a large percentage of iron.

As controls, sections of lungs from a large number of miners on the Rand who had died from silicosis and tuberculosis were examined. Bodies such as have been described above were found in none of these, nor was the Prussian blue reaction or other test for iron positive except in those cases where the pigment was obviously of haematogenous origin. A single case of a miner was also investigated; he had worked for twenty-eight years in the haematite mines in the North of England, and subsequently for seven and a quarter years in the gold mines of the Rand, South Africa. The cause of death was carcinoma of the gall-bladder. Macroscopically the pulmonary root glands were enlarged, pigmented, and fibrosed. The pigment was dark rust-coloured and gave a marked Prussian blue reaction with dilute hydrochloric acid and potassium ferrocyanide. Occasional rust-coloured subpleural islets were visible. On section the lungs showed a slight diffuse fibrosis and a few large areas of fibrosis. The whole lung gave a marked iron reaction. Histological sections of the large areas showed moderately well defined, but irregularly shaped, masses of well-formed acellular fibrous tissue (Fig. 9). The alveolar walls were slightly thickened, and there was a moderate degree of connective tissue increase round the blood vessels and bronchi. A large quantity of pigment of a reddish-brown colour was contained in phagocytic cells and lying free in alveoli, alveolar walls, and between the fibres of the newly formed fibrous tissue. The greater part of this pigment gave the iron reaction. In addition, there was another variety of pigment, in much smaller quantity, in the form of crystalline refractile particles. The latter was intimately mixed with the iron-containing dust. This lung was especially examined to determine, if possible, whether the same peculiar bodies were being formed from a deposit of ferric iron dust as in the case of an asbestos dust which contained both ferrous and ferric iron. A careful and thorough search was made, but no particles with a similar appearance were detected (Fig. 10). At the time of the patient's death this case of ironstone phthisis was complicated by underground work in the gold mines on the Rand, but in 1919 it simulated, by x-ray photography and physical examination, an early case of silicosis;

and confirms the findings of Sir Kenneth Goadby<sup>1</sup> and Dr. Cronin.<sup>2</sup>

In addition to the human lungs showing asbestosis, Dr. Mavrogordato of the South African Institute for Medical Research has supplied me with the lungs of a guinea-pig which died in December, 1927, from causes other than asbestosis. This animal was exposed to an asbestos dust atmosphere experimentally. The length of exposure was two hours a day on each of fifty days. The first exposure took place on February 4th, 1925, and the last on April 1st of the same year. The asbestiform compound used for the experiments was a chrysotile<sup>3</sup> obtained from the mine in Southern Rhodesia. Histological sections showed a slight generalized fibrosis and an increase in pigment, but the interesting feature was the presence of the golden yellow bodies (Fig. 11), similar to those seen in the lungs of human pulmonary asbestosis.

A comparison between the human cases and the experimental animal showed that the fibrosis was more rapid and extensive in the human cases than in the experimental animal. This is readily explained by the difficulty in reducing the tough asbestos fibre to a uniformly fine powder, and to the presence of a comparatively small proportion of the rock dust which is usually associated with asbestiform compounds. For "dusting" animals a limited amount of dust is available, and of this only a small proportion contains particles of sufficiently small dimensions to permit of their reaching the lung alveoli. In silicosis<sup>4</sup> the size of the majority of the particles<sup>5</sup> which reach the alveoli is between  $1\mu$  and  $3\mu$ ; in the haematite lung, mentioned above, the particles appear larger, but even here are much smaller than the greater number of those prepared from asbestos for "dusting" experiments. In the working mill the conditions are very different from an asbestos dust atmosphere produced experimentally. Fine dust is continuously reaching the atmosphere, and only the very fine particles remain suspended for any length of time. These gradually increase in numbers until a maximum concentration is reached, then remain more or less constant during working hours. Thus it will be seen that, in order to produce changes in experimental animals showing the same degree of fibrosis in the same length of time, an atmosphere approximating that of the working mill will have to be obtained.

The amount of fibrosis in two of the human cases (Cases I and II) was quite definite, and, if due to the presence of asbestos dust, the initial rate of production was rapid when compared with present-day non-infective silicosis on the Rand. It is difficult to state a definite time for the production of an appreciable degree of fibrosis in pure non-infective silicosis, but modern observation tends to show that it is in the neighbourhood of ten years. In Case I a moderately marked fibrosis had taken place after one year of work in the mill, but this was complicated by tuberculosis. It is known that the rate of fibrous tissue production is very much greater in dust diseases complicated by infections, but even allowing for this the connective tissue increase in Case I was rapid. In Case II there was a still more definite fibrosis after two years of work in the mill with no evidence of tuberculosis.

Before this work was completed Drs. Cooke,<sup>6</sup> Stuart McDonald, and Oliver<sup>7</sup> published their papers dealing with pulmonary asbestosis, and previous to that a short article on the same subject appeared in the *Lancet*. The similarity between the case described and ours was suspected when the first article appeared, and our work goes far to confirm the findings. As in those recorded here, the asbestos dust responsible for the changes in the lungs in their case was a chrysotile. Whether other asbestiform compounds are capable of producing these changes it is impossible to say, as there appears to be no record of any such cases in the literature.

In the Union of South Africa<sup>8</sup> and Rhodesia there are many asbestos mines, from some of which chrysotile is obtained, but two other interesting varieties are found—namely, crocidolite and amosite. Amosite is a comparatively recent discovery, the chemistry of which has not been completely worked out, but it appears to be somewhat similar to crocidolite in composition. Both these com-

pounds contain a large percentage of ferrous iron. Analysis of four samples of amosite<sup>9</sup> showed between 32 and 44 per cent. of FeO, and eight samples of crocidolite<sup>10</sup> between 16.5 and 40.5 per cent. Up to the present there has been no examination of *post-mortem* material from cases of death among those working in mills where these minerals are treated. No such material has been made available.

Chrysotile or serpentinite asbestos usually contains 2 to 3 per cent. of FeO isomorphously replacing magnesia. The analysis of Dr. Cooke's case showed 3 per cent. of FeO, and the Rhodesian mineral, according to Mr. A. L. Hall,<sup>3</sup> 2.44 per cent. Dr. McCrae of the Government Chemical Laboratory, Johannesburg, analysed the FeO content of the asbestos used by Dr. Mavrogordato in his animal experiments, and found a much lower percentage—namely, 0.45. Apparently even with very small percentages of FeO the golden yellow bodies are formed in the lungs.

With regard to the unusual structure and chemical nature of the golden yellow bodies found in the lungs in pulmonary asbestosis, until many more cases have been examined and more experimental work has been done very little can be stated. There is no doubt that they are in some way associated with the asbestos, or, probably, more particularly with the FeO content, either of the asbestos itself or of the dust of the mill. This dust contains a much higher percentage of iron, which may be derived partly from the lode from which the asbestos is mined.

Three possibilities regarding the formation of the golden yellow bodies are worthy of mention:

(1) In the form of a gel, as suggested by Dr. Stuart McDonald.

(2) As particles of ferruginous quartz formed in the lungs under conditions similar to weathering, or ferruginous quartz changed in composition as a result of combination with constituents of the body fluids. In support of this it may be mentioned that crocidolite, which is an alkali silicate with ferrous iron, is especially liable to decomposition when exposed to weathering. Sodium is removed, the iron oxidized and hydrated to form limonite, and silica set free; there then results a ferruginous quartz which possesses the finely fibrous structure of the original mineral. It is extremely hard, and coloured a rich golden yellow. It is possible that a change such as this occurs with the small quantity of ferrous iron associated with chrysotile, and the colour of the bodies in the lungs is very suggestive.

(3) Phagocytosis of these structures is a very prominent feature in the lungs, and it was thought that the action of these cells may have been responsible, first, for some change in chemical composition, then a building up and moulding into the various shapes seen.

The fibrous tissue change in the lungs of the above-mentioned cases of workers in asbestos mills is probably the result of a reaction on the parts of the tissues to both the golden yellow bodies and a small quantity of silica.

Sufficient cases of pulmonary asbestosis have not been recorded to base an opinion upon the liability to secondary infection by specific inflammatory processes such as tuberculosis, but it is very suggestive that two of those now recorded, which have been examined histologically, have shown tuberculosis complicating the changes produced by an asbestos dust occupation of the lungs.

Besides these cases there is still further evidence in favour of tuberculosis being a complicating factor.

Dr. H. M. Murray reported a fatal case in the *Charing Cross Hospital Gazette* in 1900; and in the United States of America, from one source,<sup>11</sup> during the period 1907 to 1914 there were 13 deaths, 3 of which were from tuberculosis.

In 1910 Dr. Collis<sup>12</sup> reported on the relationship of asbestos dust to pulmonary tuberculosis, and found that 5 deaths from phthisis had occurred in five years amongst a staff of less than forty workers employed at a factory where asbestos is woven.

In conclusion, I wish to record my thanks to Dr. Mavrogordato for data and material from an experimental animal; to Dr. Irvine, chairman of the Miners' Phthisis Medical Bureau, Johannesburg, for material from silicotic cases and from the lungs of a haematite miner; to Dr. McCrae for his analysis of the FeO content of a sample of asbestos; and to Mr. P. Longmore for his valuable assistance in preparing the microphotographs.

## ABDOMINAL PAIN AS EXEMPLIFIED IN ACUTE APPENDICITIS:

### A CLINICAL AND BIOLOGICAL CONSIDERATION.\*

BY

JOHN MORLEY, CH.M., F.R.C.S.,

HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY;  
 HONORARY CONSULTING SURGEON, ANCOATS HOSPITAL; LECTURER  
 IN APPLIED ANATOMY, MANCHESTER UNIVERSITY.

### THE EVOLUTION OF OUR KNOWLEDGE OF ABDOMINAL PAIN.†

ALMOST the first considerable contribution to our knowledge of the mechanism of abdominal pain was made by J. Ross of Manchester<sup>1</sup> in 1887. Ross held that there were two kinds of pain in visceral disease—true splanchnic pain, felt in the affected organ; and associated somatic pain, referred to the cerebro-spinal nerves of the body wall. Lonnander<sup>2</sup> established the insensibility of the exposed gastro-intestinal tract to the ordinary painful stimuli, and attributed all abdominal pain to stimulation of nerves in the sensitive parietal peritoneum. Mackenzie, whose views form the orthodox teaching of the current textbooks, accepted Ross's views on somatic pain, but rejected splanchnic pain as non-existent. He believed that painful stimuli passed from the viscera through the afferent splanchnic nerves to the spinal cord, but were only appreciated by the brain as arising from the sensory nerves of the parietes. Mackenzie's theories of a viscerosensory and visceromotor reflex have been widely accepted, and will be discussed later. Hurst<sup>3</sup> in 1911 published observations which have restored our belief in true splanchnic pain; he proved that this type of pain is produced by a single adequate stimulus—namely, increased tension in the muscular wall of the viscus concerned. Yet Hurst does not reject Mackenzie's views on the viscerosensory and visceromotor reflex mechanism.

My purpose in this paper is to discuss the light which a study of acute appendicitis throws on the mechanism of abdominal pain; and since Mackenzie's theories were based very largely on his observations in cases of appendicitis, this disease may reasonably be used to test those theories.

### THE TWO PAINS IN APPENDICITIS.

The conventional teaching on the pain in acute appendicitis is that the attack is ushered in by pain referred to the region of the umbilicus or a little above it, and that after a few hours the pain becomes localized in the right iliac fossa or moves down into that region.

#### The Initial or Central Pain.

The first point that I wish to emphasize is that the initial pain is entirely different in character and in its mode of origin from the pain which appears in the right iliac fossa a few hours later. The initial pain is felt in the centre of the abdomen, and though the patient may refer it to the mid-line at or above the umbilicus, he often describes it as "all across," sweeping his hand evenly across the central region of the abdomen. It is, in short,

very imperfectly localized. The pain is often described by the patient as "like an ordinary bellyache, but more severe." It is frequently gripping in character and varies in intensity; the more severe spasms usually occur at more or less regular intervals, and last for a few seconds, during which the patient moans and writhes restlessly in bed. This early pain is entirely unassociated with any tenderness on palpation, and the patient may rub or press on his abdomen in a vain attempt to secure relief—a thing that he never does when the second pain has appeared.

This initial pain in appendicitis is, I believe, a true splanchnic pain, and, like all true splanchnic pain, is due to increased tension on the muscular wall of the viscus concerned. Some degree of obstruction to the lumen of the appendix, causing retention of inflammatory exudate distal to the obstruction, is an essential factor in its production. Sometimes—in fact, it is almost the rule in the most fulminating cases—we find a hard, laminated faecal concretion engaged in the relatively narrow base of the appendix, while distal to it a collection of foul pus under great tension runs the concretion home into the base. In this condition, so well described by Wilkie<sup>4</sup> as acute appendicular obstruction, the central pain in the umbilical region continues until general gangrene or localized perforation of the appendix relieves the tension within it and the pain disappears. In other cases a stricture at the base, the result of some former ulceration, gives rise to the same sequence of events. In others a kinking at the base combines with inflammatory swelling of the mucosa to occlude the outlet into the caecum. In yet rarer instances a foreign body is the occluding agent. A critical examination of the specimens removed in a large number of cases of early appendicitis has convinced me that wherever this splanchnic pain is present some degree of obstruction to the lumen, with retention of inflammatory exudate under tension beyond it, will be found. It is possible that the inflamed condition of the appendix lowers the threshold of painful stimulation and allows a relatively slight distension to cause pain; but without increased tension visceral pain is impossible.

Under certain conditions recurrent attacks of appendicitis may occur in which this splanchnic central pain is the only evidence of the disease, and great difficulty in diagnosis results. A striking instance of this difficulty was afforded by a man, aged 21, who gave a history of four severe attacks of epigastric pain, each lasting for a few hours, during the course of four months. There had been neither tenderness nor muscular rigidity during the attacks. Exploration a week after the last attack showed that the only viscus affected was the appendix, which was swollen and congested in its distal portion. There was a narrow stricture at the base, and, distal to this, a collection of thick yellow pus. In the ten months that have passed since the operation there have been no more attacks.

It is evident that this patient was suffering from recurrent attacks of acute obstructive appendicitis of too mild a type to cause perforation, and that his pain was of the pure splanchnic appendicular type. The reason for the entire absence of local pain and rigidity I shall discuss later, when dealing with the second pain. The brief intermittent colicky attacks of central abdominal pain so common in children, and described by physicians as "umbilical colic," are very commonly due to spasmodic efforts to expel a concretion or a nest of threadworms from the appendix, and form another example of pure splanchnic pain.

Although the splanchnic pain in acute appendicitis is felt in the umbilical or lower epigastric region, and not in the region of the appendix, it should not be described as referred or reflected pain, as no radiation of pain or reflex process is involved. The appendix is developmentally a part of the mid-gut loop. The brain can only appreciate painful stimuli arising from any portion of the mid-gut as vaguely situated in the centre of the abdomen, and stimuli of appendicular origin are no exception to the rule. It is characteristic of this splanchnic pain that it is dull and aching in character—as patients express it, "like an ordinary bellyache"—and vaguely localized; in other words, it is a form of Head's protopathic pain.

\*A short paper read at the Royal Infirmary, Manchester, and published in the *Lancet* abridged.

*The Second or Localized Pain.*

A few hours after the onset of the acute attack the second pain makes its appearance in the right iliac fossa. The initial splanchnic pain is usually still present, but it tends, either gradually or suddenly, to sink into insignificance. The new pain is entirely different in character from its forerunner. It is localized, severely at first, to the right side. It has a sharp or stabbing character. Any movement of the abdominal muscles, as in deep breathing, vomiting, or coughing, accentuates the pain, and the right iliac fossa becomes exquisitely tender on palpation. The patient no longer writhes in pain, but lies still in bed, resenting any movement and even complaining of the pressure of the bedclothes. The respiratory excursions of the lower abdominal wall are now increasingly limited.

Since the cutaneous and muscular phenomena interpreted by Mackenzie as the viscerosensory and visceromotor reflex have received such general attention, we must now consider them in detail.

**CUTANEOUS HYPERALGESIA IN ACUTE APPENDICITIS.**

Mackenzie's theory of a viscerosensory reflex was based on his observation that in certain abdominal diseases areas could be mapped out in which the skin of the abdominal

FIG. 1.—To illustrate Mackenzie's theory of a viscerosensory and visceromotor reflex. S=Skin. M=Abdominal muscles. P=Parietal peritoneum. I=Intestinal tract.

wall could not be lightly pinched up and drawn away from the underlying muscles without evoking pain. Impressed by the similarity between these areas and the skin areas mapped out by Head in cases of herpes zoster Mackenzie made the assumption that afferent stimulation through the splanchnic nerves from the inflamed viscera caused an irritable focus in its own centre of grey matter in the cord, as a result of which the sensory nerves from the skin supplied by the same spinal segment became excessively irritable. (Fig. 1.) Stimuli, such as a light pinch of the skin, which normally cause no pain, in the presence of visceral inflammation, so Mackenzie taught, become painful. Then, regarding his viscerosensory hypothesis as proved, he next argued that from these hyperalgesic areas we could, by comparison with Head's diagrams, deduce the segmental innervation of the affected viscera. He also laid great stress on the value of these areas of hyperalgesia in the diagnosis of acute abdominal catastrophes.

Sherren<sup>5</sup> attempted to systematize the matter by investigating the hyperalgesia present in a series of 124 cases of acute appendicitis. He found cutaneous hyperalgesia in 40 of these, and described a cutaneous triangle of hyperalgesia over the right iliac fossa in a majority of the positive cases. Sherren's views as to the mechanism of this reflex clearly conform closely with those of Mackenzie, for he believes that hyperalgesia is never present where the appendix is gangrenous or perforated, and goes so far as to teach that disappearance of the hyperalgesia may constitute an important indication for immediate operation. He also states that cutaneous tenderness does not vary with the position of the appendix.

It appears to me necessary to consider two points in connexion with hyperalgesia in acute appendicitis—namely, its value in diagnosis, and the mechanism of its production.

*The Value of Hyperalgesia in Diagnosis.*

There is a marked discrepancy between the statements of different observers as to the frequency of hyperalgesia in acute appendicitis. Sherren, in 124 cases, found hyperalgesia in 40, or 32 per cent. Robinson,<sup>6</sup> in 123 cases, found hyperalgesia in 26, or 21 per cent. Zachary Cope<sup>7</sup> found hyperaesthesia (not amounting to pain) in 110 of 185 cases, or 59 per cent. Further, both Robinson and Cope differ from Sherren in finding that hyperalgesia and hyperaesthesia occur quite frequently with a gangrenous or ruptured appendix, and with this opinion my own observations are in full agreement.

A phenomenon that can be detected by different observers with a frequency that varies from 21 to 59 per cent. would appear to be of but little help in diagnosis. Unless, given certain pathological conditions in the appendix, hyperalgesia can be detected as a constant phenomenon, I hold that it is merely of academic interest.

A further consideration which invalidates hyperalgesia as an aid to diagnosis is the extreme frequency with which it can be elicited over the appendix in the neurotic abdomen, or those cases simulating chronic appendicitis, where on exploration no evidence of organic disease in the appendix or any adjacent organ can be found.

*The Mechanism of Production of Hyperalgesia.*

All observers are agreed that when hyperalgesia is present in acute appendicitis it is found, in the vast majority of cases, in some part of the right iliac fossa only. If we accept Mackenzie's hypothesis that it is due to stimuli arising in the appendix and travelling by way of the splanchnics to the spinal cord, we should expect it, however, to be bilaterally symmetrical. The appendix is a portion of the embryonic mid-gut loop. It becomes fixed in the right iliac fossa relatively late in the development of the embryo, and long after it has received its splanchnic innervation. As a developmentally median organ its nervous connexions are presumably with both sides of the spinal cord, and consequently Mackenzie's hypothesis as to the origin of the hyperalgesia would appear to be at variance with anatomical evidence. Zachary Cope, in the article quoted previously, suggests that irritation of the sensitive parietal peritoneum may in many cases determine the presence of right-sided hyperaesthesia, yet he goes on to argue that some evidence is furnished by his cases to show that the appendix is supplied mainly by the tenth dorsal segment; thus he tacitly accepts Mackenzie's viscerosensory reflex.

My own conclusions are that the hyperalgesia is a phenomenon in which the splanchnic afferent nerves take no part. I believe that the nerves of the exquisitely sensitive parietal peritoneum affect their cutaneous branches by radiation, and that the process is precisely analogous

FIG. 2.—To illustrate the mechanism of peritoneo-cutaneous radiation, and the peritoneo-muscular reflex. S=Skin. M=Abdominal muscles. P=Parietal peritoneum.

with the cutaneous hyperalgesia along branches of the fifth cranial nerve so often present in toothache. (Fig. 2.) The communication or synapsis rendering this radiation possible probably takes place in the posterior root ganglia of the nerves concerned. On account of its inconstancy, however, the practical value of hyperalgesia in clinical medicine has been greatly overestimated.

### MUSCULAR RIGIDITY IN ACUTE APPENDICITIS.

We have, however, in connexion with the localized pain of acute appendicitis an objective phenomenon of prime importance because of its constancy under certain well-defined conditions. This is the deep tenderness on gentle palpation with the flat of the hand over the appendix, associated with reflex and involuntary muscular rigidity. In order to appreciate the extent and degree of this muscular rigidity it is necessary to have the patient lying at ease on his back, with the head well supported on a pillow. Gentle pressure with a warm hand on the unaffected left iliac fossa through a full respiratory cycle gives a standard of comparison. The hand is then transferred to the area of pain in the right iliac fossa, and again exerts gentle pressure through one or more respiratory cycles. The hard, unyielding contraction of the affected area of the flat muscles, the corresponding immobility of the muscle in full expiration, and the marked tenderness on pressure over the contracted muscle can then be readily appreciated and the extent of the rigidity determined. The area of muscular rigidity and tenderness corresponds accurately with the area to which the patient points when asked to indicate the position and extent of his pain.

### The Value of Muscular Rigidity and Tenderness in Diagnosis.

By noting the exact position and extent of the muscular rigidity and tenderness in an early case of appendicitis, at a stage when the initial splanchnic pain has given place to the sharper pain in the right iliac fossa, but before perforation and spreading peritonitis have confused the picture, it is possible to predict with the greatest accuracy the position in which the inflamed appendix will be found. When the appendix is curled up on the outer side of the caecum the maximum rigidity is found close to the anterior superior iliac spine; when the appendix is pointing upwards towards the spleen the maximum rigidity is nearer to the umbilicus than the conventional McBurney's point. In the rare undescended caecum the maximum rigidity is higher than usual, and corresponds with a point just below the lower margin of the right lobe of the liver. Where the appendix hangs over the brim of the pelvis the rigidity is in the lower part of the rectus muscle, well below and internal to a line joining the anterior superior spinae and the umbilicus. With a prolapsed caecum which has dropped low into the pelvis there may be no rigidity or tenderness on palpating the abdominal wall; but in such a case rectal examination will usually reveal marked tenderness on pressure by the finger from within towards the right side of the rectum. In this early stage the accuracy with which the inflamed appendix can be located is remarkable. One striking instance will suffice.

A woman, aged 50, became ill with "pain in the umbilical region and vomiting. When seen fifteen hours after the onset there was no abdominal rigidity or tenderness, but on rectal examination pressure towards the right wall of the pelvis caused intense pain. I diagnosed an inflamed pelvic appendix. For domestic reasons some delay ensued, and I saw her again twelve hours later. She had now typical tenderness and rigidity in the right iliac fossa, while the tenderness per rectum had almost disappeared. I remarked before operating that she must have a very mobile caecum, which had moved up out of the pelvis between my two visits, dragging the appendix with it. Operation disclosed precisely that condition. The caecum was so loosely attached that it could be lifted through the wound six inches above the abdominal wall, and the appendix, which was long and free from effective adhesions, was acutely inflamed and covered with flakes of plastic lymph. The appendix and caecum were found lying in the iliac fossa well above the brim of the true pelvis. From the condition found I have no doubt that the change in position that I had predicted had actually taken place.

### THE MECHANISM OF REFLEX MUSCULAR RIGIDITY AND ASSOCIATED DEEP TENDERNES.

The arguments that I have advanced against Mackenzie's hypothesis of a viscerosensory reflex apply with an even greater cogency to the theory of a visceromotor reflex by which he attempted to explain the phenomenon of protective rigidity in appendicitis. The almost invariably unilateral position of the rigidity makes the agency of the splanchnic nerves improbable, because, as I have argued above, the appendix is developmentally not a right-sided but a median organ; and the far greater constancy of muscular rigidity than of cutaneous hyperalgesia in acute

appendicitis lends greater strength to this argument. Mackenzie himself appreciated the difficulty, as he admits in his work on *Symptoms and their Interpretation*, where he says (p. 175, fourth edition): "I cannot satisfactorily account for the predominant symptoms from the appendix being so distinctly one-sided, seeing that it is developmentally a portion of the digestive tube." But even if we could accept the tacit assumption underlying Mackenzie's theory that there is a specially intimate connexion through the splanchnic nerves between the appendix and the right side of the spinal cord, how are we to reconcile it with the fact—which I have so many times verified—that the area of muscular rigidity and deep tenderness corresponds exactly with the position of the appendix? If the visceromotor reflex were a fact, the muscular rigidity produced by it would be constant in position, since it would be determined by the segmental innervation of the appendix, and would be entirely unaffected by the position in which the appendix happened to be lying in relation to the abdominal wall.

I find, then, that the clinical investigation of the distribution of muscular rigidity in appendicitis reveals facts that are entirely inconsistent with Mackenzie's visceromotor reflex theory. Nor am I aware of any physiological experiments which make it probable that such a reflex exists, nor of any anatomical evidence of a communication in the cord between splanchnic afferent and somatic efferent motor fibres. The whole theory appears to me to be an unsound extension of Ross's theory of somatic referred pain, based upon a mistaken interpretation of clinical and operative findings. Mackenzie did not appear to appreciate the exquisite sensitiveness of the parietal peritoneum to even slight degrees of inflammation. Had he done so I believe that so acute a mind as his would have perceived that in a peritoneo-muscular reflex lies the explanation of this protective muscular rigidity, and that the splanchnic afferent nerves have nothing to do with the reflex rigidity in appendicitis.

The cumulative effect of correlating pre-operative symptoms with operative findings in acute appendicitis has convinced me that the second or localized pain in the disease is entirely dependent on stimulation of the sensitive parietal peritoneum. (Fig. 2.) In cases such as the first one quoted above, where recurrent attacks of obstructive appendicitis gave rise to the epigastric splanchnic pain alone, the parietal peritoneum was shielded from the appendix by a fairly thick omentum; and as the degree of inflammation was too mild to penetrate through the thick walls of the appendix and the omentum the parietal peritoneum was not affected. This explains the complete absence of localizing pain or rigidity, and the difficulty in diagnosis. An appendix wrapped round by omentum and coils of small intestine as a result of some former attack will, in fat patients, often give rise to no characteristic right-sided pain or rigidity until it has perforated. This absence of rigidity is particularly liable to occur if the caecum and appendix are lying low in the true pelvis. But a degree of inflammation so slight as to cause but a little congestion of the outer serous coat of the appendix and a trifling fibrinous deposit will, provided it lies within reach of the parietal peritoneum, cause the most accurately localized tenderness and rigidity. Should perforation occur the rigidity and tenderness extend *pari passu* with the inflammation of the parietal peritoneum, while from the moment of perforation all the initial splanchnic pain disappears.

### THE PERITONEO-MUSCULAR REFLEX AND PERITONEO-CUTANEOUS RADIATION.

Since the parietal peritoneum is supplied by the same cerebro-spinal nerves as the overlying muscles and skin, the accuracy with which an inflammatory stimulus from within the abdomen is localized can be easily understood. It is necessary, however, to insist that a true nervous reflex mechanism through the governing centre in the spinal cord is involved. The tonic contraction of the affected area of muscles, recognized on palpation as a hardness that never relaxes during the whole respiratory cycle, makes it impossible for us to believe that we are pressing on the inflamed parietal peritoneum itself. The pressure required to appreciate the muscular rigidity is too light to have any

influence of that kind, and even on inspection alone the tonic muscular contraction may readily be appreciated, if we observe the limitation of respiratory movements in the lower rectus muscle.

The peritoneo-cutaneous radiation is best appreciated by a consideration of the shoulder-tip pain resulting from stimulation of the parietal peritoneum lining the under-surface of the diaphragm. In some observations on this shoulder-tip pain<sup>8</sup> I have drawn attention to the fact that whenever the sensory terminations of the phrenic nerve under the diaphragm are stimulated, either mechanically or by inflammatory exudate, a pain is felt over the corresponding shoulder in the area supplied by the third and fourth cervical nerves. This shoulder-tip pain is of special interest as proving a peritoneo-cutaneous reflection or radiation of the painful stimulus. By the descent of the diaphragm in the embryo this area of parietal peritoneum becomes widely separated from its corresponding skin area, and thus an embryological event, dependent on the development of the lungs, enables us to observe the working of the pain-producing mechanism. While I have proved the invariability of shoulder-tip pain where the diaphragm is stimulated, I have not found the same constancy of cutaneous hyperalgesia as tested by light pinching over the acromion process. In some cases the patients describe the pain as akin to rheumatism in the shoulder, and deny any tenderness on light pinching or deep pressure. In some instances tenderness is felt, but only on deep pressure on to the acromion process, while in others definite hyperalgesia is felt on light pinching.

It cannot be doubted that a similar radiation or spreading of painful stimuli from the parietal peritoneum to the skin overlying it via the spinal cord occurs in the anterior abdominal wall, though the proximity of skin to peritoneum has prevented its recognition. When the under-surface of the diaphragm in a patient under spinal anaesthesia is stimulated by the insertion of a gauze swab between the liver and the diaphragm, the patient complains of pain in the shoulder-tip area, but feels no pain locally. So, when the parietal peritoneum is stimulated I believe that the pain is felt in the skin and subcutaneous tissue alone. The exact position in the nervous system of the synapses necessary to produce this radiation is uncertain. The teaching of Mackenzie and Ross would lead us to expect to find it in the grey matter of the posterior horn of the cord, but there would appear to be a greater probability that it lies in the posterior root ganglia. (Fig. 2.)

If I have succeeded in proving my contention that the muscular rigidity in acute appendicitis is a reflex result of peritoneal stimulation alone, the diagnosis of acute appendicitis becomes a far simpler clinical problem. Mackenzie himself, obsessed by his theory of a visceromotor reflex, taught that it was impossible to separate the symptoms produced by the inflamed appendix from those produced by the inflamed parietal peritoneum. From my experience in teaching students I am sure that the widespread acceptance of Mackenzie's doctrine has introduced an unnecessary difficulty into the diagnosis of abdominal lesions. The student, picturing muscular rigidity as a reflex from the inflamed organ through the splanchnic afferent nerves, and conscious that peritonitis produces a similar effect, finds a hopeless impossibility in the task of distinguishing between the two processes, and is apt to regard abdominal diagnosis as very largely guesswork. But if he can be taught that true reflex involuntary rigidity is the result of stimulation of the parietal peritoneum, and of that alone, and that the only true pain felt in the gastro-intestinal tract is a splanchnic pain due to increased tension and exaggerated peristalsis, the investigation of a case of acute abdominal disease becomes relatively straightforward.

#### A BIOLOGICAL CONSIDERATION OF ABDOMINAL PAIN.

I will finally sketch in briefest outline what I conceive to be the biological or evolutionary aspect of abdominal pain. With the development of the alimentary tract and the peritoneal cavity a great responsibility for the protection of the abdominal viscera was laid upon the parietal peritoneum. To guard against bacterial invasion of the peritoneal cavity from without by penetrating wounds, or

from within by perforation of a hollow viscus, the parietal peritoneum was endowed with nerves of exquisite sensitivity to mechanical or chemical insult. Stimulation of this layer produced reflex guarding of the overlying muscles, with pain felt in the skin and on the surface of those muscles. At the same time another reflex—not dealt with in this paper, but also provided by the parietal peritoneum, the splanchnic provided to secure rest to the intestinal tract and so to avoid the diffusion of septic material by peristalsis.

Against the danger of intestinal obstruction another mechanism had to be elaborated. Violent peristaltic efforts of myogenic origin attempted to overcome the obstructing force, and their occurrence was registered by painful afferent stimuli through the splanchnic nerves, appreciated by the brain as spasmodic in character, and vaguely localized in the centre of the abdomen. This splanchnic pain would seem to be the more primitive in order of evolution. It is akin to protopathic pain in its dull character and in the absence of precise localization. Moreover, a considerable stimulus is needed before consciousness of pain is produced.

#### SUMMARY.

1. The evolution of our knowledge of the mechanism of abdominal pain is summarized.
2. The initial central pain in acute appendicitis is a true splanchnic pain, due to increased intra-appendicular tension.
3. The localized right-sided pain is due to irritation of the parietal peritoneum.
4. Cutaneous hyperalgesia is too variable in its incidence to be of value in the diagnosis of acute appendicitis.
5. The mode of production of cutaneous hyperalgesia is discussed. Mackenzie's viscerosensory reflex theory is criticized.
6. The mechanism of reflex muscular rigidity and the associated deep tenderness is discussed. Mackenzie's visceromotor reflex theory is criticized, and the role of the parietal peritoneum emphasized, protective muscular rigidity being ascribed to a peritoneo-muscular reflex.

I am indebted to Professor J. S. B. Stopford, M.D., F.R.S., for his kindness in drawing the diagrams illustrating this paper.

## AN OPERATION FOR THE CURE OF PROLAPSE OF THE RECTUM IN THE FEMALE.\*

BY

FREDERICK J. McCANN, M.D., F.R.C.S.

THE aim of the operation herein described is to restore the muscular retentive mechanism which prevents the bowel prolapsing after each act of defaecation.

In July, 1913, a single woman, aged 51, came to see me; she had undergone an operation for rectal prolapse four years previously, the prolapsed portion of the bowel being excised. The operation was, unfortunately, a failure. The bowel still prolapsed for nearly two inches and the anal orifice surrounded by scar tissue admitted three fingers. She had complete incontinence of faeces, and was unable to earn her living as a nurse. Her condition was deplorable, and her nervous system had suffered considerably in consequence. She was reluctant to undergo another operation, but ultimately yielded to persuasion.

The bowel was returned and the patient was placed in the elevated lithotomy position; an incision was then made around the anal orifice anteriorly and laterally for three-fourths of its circumference. The perineum was incised in the middle line from the fourchette to the anal orifice; this incision was further prolonged anteriorly into the labium of each side for about an inch and a half. The lower end of the rectum was freed by dissection anteriorly and laterally, exposing the levator ani on either side, whilst the lower portion of the posterior vaginal wall was dissected upwards for about two inches. A V-shaped piece was then cut out

\* Abstract of a paper read before the Subsection of Proctology, February 8th, 1923. *Proc. Roy. Soc. Med.*, vol. xxi, No. 5, p. 891, March, 1923.

of the anterior rectal wall and the anterior margin of the anal orifice. The cut edges were united by catgut sutures, after tying the bleeding vessels. The scar tissue surrounding the anus was dissected out, and the anal orifice reconstructed to the requisite size by a series of catgut sutures passed so as to take a grip of the sphincter ani, and to avoid the mucosa of the bowel. A V-shaped piece was next removed from the posterior vaginal wall, followed by the suture of the levatores ani muscles in front of the lower end of the rectum. The cut edges of the posterior vaginal wall were then sutured together by catgut sutures, which were passed through the united levatores ani muscles, and when tied brought the latter in close apposition with the posterior vaginal wall. Silkworm-gut sutures were passed through the perineal tissues to coapt the divided perineal body, and further to coapt the already sutured levatores ani muscles. The skin edges were finally united with catgut, whilst a special silkworm-gut suture was inserted to prevent the anal orifice falling backwards.

The patient made a smooth recovery and regained complete control of her anal sphincter. She has, moreover, remained well up to the present date, and has expressed herself as being completely cured. She has been enabled to discharge her duties as a nurse and to lead a life of unusual activity. The result of this operation satisfies the time test, for the patient has remained perfectly well up to the present date—that is, for thirteen years.

On thinking over this operation I concluded that it was unnecessary to excise a portion of the rectal wall and anal margin (as that procedure only led to scar formation) instead of building up and strengthening the anal sphincter, which could be done much better without

and had her last confinement twenty-nine years previously. She had had slight rectal prolapse and loss of control ever since her last child was born. When she presented herself for examination the rectum protruded for four inches, and she informed me that the amount of rectal prolapse had been gradually increasing. There was no evidence of ulceration.

It is essential that such patients should have a preliminary period of rest in bed, not only for purposes of local cleansing, but because congestion is diminished in those who have struggled to be about. The prolapsed bowel should be returned, and if possible retained, which still further diminishes local congestion.

During the operation the elevated lithotomy position is employed in order to diminish the tendency to protrusion of the rectum. An incision is made around the dilated anal orifice anteriorly and laterally for three-quarters of its circumference. A mesial incision is then made from the anal orifice

to the fourchette, which, when deepened, splits the perineal body (Fig. 1). This incision is prolonged at its anterior extremity outwards and forwards into each labium. The anal sphincter and the lower end of the rectum are exposed by dissecting away the superjacent tissues, and the posterior vaginal wall is dissected upwards for about two inches (Fig. 2). Catgut sutures are now introduced grasping the sphincter ani, being passed on one side from within outwards under the sphincter muscle and avoiding the mucosa, and in the reverse order on the opposite side, and are then tied. A sufficient number of these sutures are introduced to restore the anal orifice to the normal size, and when a good grip of the sphincter muscle is taken by the sutures this muscle is strengthened and tightened; and a normal anal aperture is constructed. Sutures of catgut are further used to tighten the stretched

FIG. 1.—The smaller diagram shows the prolapse of the rectum. The larger diagram shows the line of the incision after the prolapse has been returned.

FIG. 2.—Levatores ani exposed together with the sphincter ani. The vaginal flap has been reflected upwards. A, Levator ani. B, Sphincter ani. C, Vaginal flap.

FIG. 3.—Sutures in position. V-shaped piece excised from vaginal flap. A, First of a series of catgut sutures to reconstruct anal orifice. removing any portion of the bowel; and although the functional result had been so good, yet I believed that avoiding a scar would be even better. I was able to put my ideas into practice when this patient brought her sister to me in October, 1924, and the operation I performed on her appears to be suitable for the majority of cases. This woman was 65 years of age, the mother of three children,

FIG. 4.—Operation completed. Silkworm-gut sutures tied through small pieces of india-rubber tubing.

or torn fascia over the lower end of the rectum and to reinforce any weak spots.

A sufficient number of silkworm-gut sutures are next inserted; these pass inwards through the skin and levator ani muscle on one side and outwards through muscle and skin on the opposite side. The levatores ani muscles are then united by catgut sutures. A V-shaped piece is excised from the posterior vaginal wall, and the edges united by catgut sutures, which, when passed, also take a grip of

the levatores ani muscels, in order to bring these muscels and the posterior vaginal wall into close apposition (Fig. 3). The skin edges are next united with interrupted catgut sutures and the silkworm-gut sutures tied through small pieces of india-rubber tubing, thus completing the operation (Fig. 4). The last or most posterior silkworm-gut suture is passed so as to prevent the anal orifice falling backwards, which is not infrequent after operations for complete rupture of the perineum. Catgut may also be employed for this suture.

A "sacral anus" is a complication which should not be encountered where the necessary precautions have been taken during the operation to restore the anal canal. After this operation I believe it is best to refrain from administering purgatives at least for some days in order that healing may remain undisturbed. Should the patient be uncomfortable in consequence of the bowel not acting, warm olive oil should be run into the rectum through a small india-rubber tube, and a dose of castor oil given by the mouth. The bowels should afterwards be kept acting by a gentle laxative.

The result of the operation described was completely satisfactory, the wounds healed well, and there was complete sphincteric control. The patient has been enabled to be about and lead an active life, whereas formerly she was more or less of an invalid, spending most of her time either in bed or on a couch, and being forced to give up her business in consequence of her physical suffering.

When writing this paper I received unexpectedly a letter from this patient, in which she states:

"I am writing to tell you the operation has proved a perfect success. It was some time before the bowels acted naturally, but now I am like another woman. I was a long time making up my mind to the operation, but I am glad I did, and I am very grateful to you for your care and skill. I only wish other sufferers knew the benefit."

Although this type of operation remedies the anatomical defects which seem to accompany this variety of prolapse, yet congenital predisposition is an etiological factor which cannot be overlooked, for these two women were sisters, and I am informed that another sister and two cousins suffer from rectal prolapse. Exercises to cause contraction of the levatores ani muscels and sphincter ani should be practised after this operation, and such exercises are still more necessary in the presence of congenital muscular weakness. Finally, this operation offers a prospect of cure, not merely to the surgical derelicts cast adrift because of the failure of other methods, but to those who bear their suffering not knowing that anything can be done for their relief, as well as to those who from knowledge of failures have lost faith in modern surgery.

## SPIRIT AND BIPP TREATMENT.

BY

N. L. MAXWELL READER, M.S.LOND., F.R.C.S.,

BARRY.

PROFESSOR RUTHERFORD MORISON's bipp treatment is not, I think, always clearly understood, and if employed haphazardly and without attention to detail may be disappointing. The following case, which recalls that of Dr. Monica Bell and Professor Morison (December 10th, 1927, p. 1077), shows a remarkable result obtained by the use of this procedure.

On December 7th, 1927, a feeble old lady of 77 was knocked down by a motor lorry and sustained a severe compound comminuted fracture of the lower end of the right tibia and fibula, involving the ankle-joint. She was brought into the Barry Surgical Hospital suffering from shock and haemorrhage. Although a rough tourniquet had been tied round the leg the wound was still bleeding, and there was evidence from the saturation of her clothes that the haemorrhage had been profuse. A large dose of morphine and atropine was administered, and a more efficient tourniquet applied. At the end of about one hour she was sufficiently recovered from the initial shock to justify operation.

Under gas and oxygen the wound was freely opened up and the bleeding points secured. The bone was found to be badly comminuted, and many completely detached loose pieces were removed; other fragments showing a reasonable attachment to the periosteum were left. Attention was now directed to the rest of the wound. The skin edges were excised, and badly lacerated portions of muscle and fascia were removed. Fortunately it was possible to save the anterior tibial nerve; this had been completely

stripped by the violence of the injury, but remained in continuity. The wound was now freely swabbed out with methylated spirit, after which it was carefully dried, one or two additional bleeding points being secured at the same time. (There is always a fair amount of bleeding after the application of spirit.) The wound was temporarily packed with dry gauze during the changing of the gloves and towels. On resuming, a small quantity of bipp was introduced into the cavity, and thoroughly rubbed into every available nook and cranny. Lengths of thick linen thread were carefully bipped, and by their means the skin edges were roughly approximated; owing to the loss of tissue accurate apposition without tension was not possible or desirable. The dressing consisted of long pads of gauze freely soaked in spirit, each pad being liberally sprinkled with boric powder. The pads were laid along the wound and did not encircle the limb. A top dressing of wool was temporarily held in position by a bandage.

The plasters were applied as follows. The first plaster extended from above the wound to above the knee—the knee being slightly flexed during the application. The plaster was reinforced with thin laths of wood. The second plaster encircled the foot below the wound. Traction was now made on the foot by means of a weight and pulley, and when alignment of the foot was perfect the intervening space was rapidly filled in with the third plaster. Before the plasters were firmly set a large window was cut out over the wound, and the whole case was divided longitudinally from top to bottom. This division was continued through the wool and bandages until the skin was exposed. This step was an important one in view of the possibility of subsequent swelling, and the very real danger of gangrene in a patient of this age.

The patient stood the operation well, and returned to bed in a fair condition. Before leaving the theatre 500 units of anti-tetanic serum were injected. I would now also employ anti-gas gangrene serum, but I did not have a stock in readiness at the time.

**Prognosis.**—The prognosis given to the relations was a bad one. Apart from the immediate dangers of shock and haemorrhage, there remained the possibility of gangrene, and later of severe sepsis with osteomyelitis. At best only healing by granulation could be hoped for, and a very poor functional result.

**Progress.**—The old lady remained very feeble and debilitated, but no special pain was felt in the foot, and the temperature caused no alarm. There was some trouble with the bladder and bowels. On the seventh day—more from curiosity than necessity—I removed the dressing. The wound was quite dry. The skin was healthy right up to the cut edges, between which lay a hard dry mass of congealed blood. I took out the stitches and dressed the wound with spirit gauze and powder. A week later a similar dressing was applied. From start to finish not a bead of pus or even serous oozing occurred. At the end of a month the splint was removed daily for massage, and a fortnight later discarded altogether. At the present time she can bend her knee to a right angle, and can voluntarily move the foot through 30 degrees. The wound is healed and the fracture firmly united.

### Comments.

The technique used in this case was almost identical with that instituted by Professor Morison at the Northumberland War Hospital. Points to notice are:

1. The full excision of the wound.
2. The liberal use of spirit.
3. The small quantity of bipp required. This must be well rubbed into the exposed surfaces and no excess left.
4. The use of bipped sutures; this prevents infection of the needle holes and the spread of sepsis from the skin to the deeper structures.
5. The dressing with spirit and boric powder.
6. The absence of any encircling bands round the limb.
7. The infrequent dressing of the wound.

The last requires courage, but is most essential if secondary infections are to be avoided.

## AN ATYPICAL CASE OF HYPERGLYCAEMIA IN GENERAL ANAESTHESIA.\*

BY

R. L. MACKAY, M.C., B.Sc., M.D. GLAS.

(From the Wolverhampton and Staffordshire General Hospital.)

THE unusual extent of the increase in the blood sugar during general anaesthesia in the following case, combined with the absence of glycosuria or of any untoward symptoms, make it worthy of record.

A woman, aged 50 years, was the subject of a major operation on account of gastric ulcer, hour-glass stomach, and chronic appendicitis. She was prepared for operation in the normal manner, having no food on the morning of operation, and receiving 1/4 grain morphine and 1/100 grain atropine about an hour previous to the administration of the anaesthetic.

\* This case is one of a series in a research towards the expenses of which a grant has been made by the British Medical Association.

Urinary tests before operation showed no abnormality as regards the presence of albumin or of sugar. Induction of anaesthesia was by chloroform-ether mixture, and then ether was employed to maintain the anaesthesia. Blood samples were taken from the finger before, and at intervals during and after, operation, and the blood sugar content estimated by MacLean's method. At the end of operation, which consisted of partial gastrectomy, gastro-enterostomy, and removal of the appendix, since shock was present, she received a rectal saline injection, containing 5 per cent. glucose. The first two urines passed by the patient after the anaesthetic were collected and tested for glucose by the fermentation test and by Fehling's test (Bertrand's modification). The result with each test was negative. Albumin, acetone, and diacetic acid were similarly found to be absent. The patient made an excellent recovery from the operation, and was discharged later from hospital in a reasonable state of health.

The time record for this case is as follows:

Time in minutes.	
0	First blood sample taken—0.150 per cent.
10	Induction of anaesthesia begun with CE mixture.
30	Change over to closed ether.
50	Second blood sample—0.181 per cent.
75	Third blood sample—0.260 "
85	Fourth blood sample—0.359 "
100	Anaesthetic stopped.
105	Fifth blood sample—0.386 per cent.
120	Rectal saline with 5 per cent. glucose.
280	Sixth blood sample—0.229 per cent.

#### Commentary.

This case, which forms one of a series in an investigation into the blood sugar changes in general anaesthesia, is interesting for the following reasons.

First, it is an example of the fact that general anaesthesia, whether by chloroform, ether, or CE mixture, is accompanied in practically every case by an increase in the concentration of the sugar in the blood, manifest within a very few minutes of induction, and continuing, within limits, throughout the period of anaesthesia.

A. Blood sugar curve of case as here described. Anaesthesia lasted for eighty-five minutes. Sugar absent from urine, both before and after anaesthesia. This curve, which is unusually high, may be compared with the two following curves, which are more typical of those found in the longer anaesthetics.

B. Blood sugar curve in a case of gastro-enterostomy, on a man aged 60, for malignant stenosis of the pylorus. Anaesthesia lasted for fifty-five minutes, and a rectal saline was given as in Case A. Urine did not ferment with yeast after operation.

C. Blood sugar curve in a case of hydatid disease of the liver in a man aged 35. Anaesthesia lasted for seventy minutes, and there was no glycosuria before or after operation.

For purposes of comparison there has been superimposed upon the above curves and on the same scale that of curve D, which shows the course of the blood sugar after a 50 grams glucose meal, as carried out by MacLean (1925).

Secondly, this case demonstrates, that the extent of the increase may be far above that caused by the giving of a 50 grams glucose test meal, as carried out by MacLean. This is well seen by comparison with MacLean's curve (curve "D" on the accompanying figure) and the curves of two other cases (curves "B" and "C"), in which anaesthesia lasted for about an hour. These latter curves are quite typical of the usual anaesthetic hyperglycaemia, and differ only from the case here described in the degree of hyperglycaemia recorded.

Thirdly, in this case the unusual amount of hyperglycaemia to 0.386 per cent. would lead one to expect some subsequent degree of glycosuria, if the doctrine of a renal threshold for sugar of about 0.180 per cent. is to be accepted in its entirety. But such glycosuria was proved absent in this case by the two chief tests for sugar. Like-

wise, in the two other cases the curves of which are shown here, although the renal threshold was exceeded for some considerable time there was no subsequent glycosuria. As urinary secretion is not usually suppressed in anaesthesia, curves such as these lead one to doubt the validity of the renal threshold value, or to postulate for the anaesthetized state the existence of some other factor as yet unexplained.

#### Summary.

A case of anaesthetic hyperglycaemia of great extent, and unaccompanied by glycosuria, is described.

I wish to thank Mr. Deanesly, F.R.C.S., honorary surgeon to the Wolverhampton and Staffordshire General Hospital, for permission to record the details of this case.

## RUPTURE OF UTERUS EARLY IN THE FIRST STAGE OF LABOUR.

BY

GRACE STAPLETON, M.D., B.S.LOND.,

MEDICAL SUPERINTENDENT, DUFFERIN HOSPITAL, CALCUTTA.

THE following case is reported because it is of interest from several points of view. In the first place, rupture of the uterus apparently occurred early in the first stage of labour before rupture of the membranes, and without any of the usual causes, such as malpresentation or disproportion between the size of the child and the mother's pelvis. Secondly, the patient had had ten normal labours previously; all were of short duration and free from complications. Lastly, she survived the rupture, though hysterectomy was not performed until twenty-four hours had elapsed from the presumed time of its occurrence.

The patient, a European woman, aged 36, was admitted to hospital at 12.30 a.m. on October 6th, 1927, for labour at full term accompanied by severe abdominal pain. She stated that two days previously she had not been feeling well, so took castor oil, which resulted in four motions, and at 6 p.m. slight labour pains commenced. At midnight the pains were more definite, but were not severe enough to require medical aid of any sort. At 2 a.m. on October 5th, after two or three sharp pains, she suddenly felt an acute pain of a different sort; after this the child seemed to alter its position to the upper part of the abdomen, and within two or three hours its movements ceased. At the same time bleeding began from the vagina, and pain was felt on taking each breath. A doctor was called in the morning, and after an injection she slept; the bleeding became less, but on waking she felt no better. She vomited several times during the day, and from 3 p.m. the vomit was dark brown. The bowels did not act that day. As her condition was becoming so much worse she was brought to hospital at midnight.

The past history was that she had had ten children, the last one two and a half years previously. All the labours were quite normal and quick. She had never needed instruments. The last menstruation had occurred in February, 1927.

She was of medium height and nutrition, and was evidently in great pain on admission, especially in the upper part of the abdomen, which caused her to cry out all the time. The pulse rate was 110, and the tension was fairly good. The temperature was 100.4° F. and the respirations 30. The abdomen was markedly distended, especially above the umbilicus, where the outline of the dilated stomach was clearly seen; there was great tenderness all over it. The child was lying transversely across the middle of the abdomen, and was felt just under the abdominal wall; it could be moved about easily, but much pain was caused. No foetal heart sounds were heard. There was a small quantity of bright blood coming from the vagina.

The patient was so restless that a little chloroform was given for satisfactory vaginal examination. The cervix was found dilated, and the placenta lying above it was almost completely detached. The otherwise empty uterus lay on the right. On the left the membranes led out through a large tear in the lower part of the uterus and cervix, and the child could be felt lying in the ruptured bag of membranes among the intestines. Fresh bleeding was caused by the examination. A catheter was passed, and two ounces of slightly blood-stained urine were drawn off.

It was decided to open the abdomen, and the patient was prepared at once. By that time her pulse had risen to 132 and was decidedly weaker. She had vomited coffee-ground material once. Saline injections were commenced, and a 6-inch incision was made in the middle line, two-thirds being below and one-third above the umbilicus. The child, a full-term female of normal size, was

found lying free among the intestines in its bag of membranes, with the placenta still partly attached to the lower half of the uterus. There was a large rent extending from the middle of the vagina on the left side up through the cervix to about the junction of the middle and lower third of the body of the uterus; the left broad ligament had been split from far out on the lateral pelvic wall to close up against the bladder. There were only a few small clots in the abdominal cavity.

After removing the child with the placenta and membranes intact subtotal hysterectomy was performed, leaving the appendages, since they were healthy. The tear in the cervix and vagina was closed with a continuous catgut suture, and the stump of the cervix was sewn over in the same way. The abdominal wall was closed in four layers without drainage. The patient stood the operation fairly well. On her return to bed the stomach was washed out, as it had been found very distended. Within an hour after the completion of the operation, however, her condition became grave. She was restless, and her pulse had risen to 160, but by 8 a.m. she was improving, and by midday was decidedly better. By 2 p.m. the pulse rate had dropped to 130. The temperature was 98.6° F. and the respirations 30.

After this the patient made steady progress. There was a slight degree of fever for the first six days, up to 100°, and once to 100.5° F.; then the temperature became normal for three days, rose slightly on the two following days, and after that returned to normal. Her pulse was 100 to 120 for the first few days.

At the end of the first week slight thickening was felt in the upper part of the broad ligaments on either side, but there was very little tenderness. The patient took her food well from the first. The wound healed by first intention, and she was discharged well on October 24th.

The patient was seen a month later, and, except for moderate anaemia, was doing well. On vaginal examination the pelvic contents appeared quite normal, and there was no sign of cellulitis. The cervix was patulous on the left side on the site of the old tear.

The specimen was sent to the gynaecological museum of the Calcutta Medical College Hospital.

## THE PROMOTION OF CALCIUM RETENTION.

BY  
OSCAR LOEW, Ph.D.,

PROFESSOR OF PHYSIOLOGICAL CHEMISTRY AT MUNICH UNIVERSITY.

THE success of calcium therapy is so dependent upon the degree of retention it achieves that satisfactory results can only be expected when the principles underlying calcium retention receive at least as much attention as its administration. Even in the discussions on the therapeutic uses of calcium salts at the Annual Meeting of the British Medical Association last July, this close connexion does not appear to have been sufficiently emphasized.

Unless the principles of calcium retention are given the consideration their importance deserves, failures and incorrect conclusions as to the value of calcium therapy are the inevitable results. In some cases there would be no retention of calcium, but, on the contrary, an increased loss, since it favours acidosis. When the dose of calcium chloride is as heavy as 10 grams a day—and as much has been given by one physician—it is not surprising that the results are so entirely disappointing as to bring calcium therapy into disrepute.

Acidosis is readily recognizable by the increased acidity of the urine, and the higher the degree of acidity the more lime the urine has withdrawn from the blood; as was shown by Schetelig in 1880 and confirmed more recently; the weaker also must have been the alkaline reaction of the blood from which the urine was excreted. It is therefore a logical inference that the losses of calcium are smaller (or the calcium retention is greater) when the degree of blood alkalinity is high. This degree corresponds under normal conditions with 0.3 per cent. of sodium carbonate (or bicarbonate in the venous blood). In other words, as the blood alkalinity decreases the calcium loss in the urine rises above the normal, which is 0.2 gram in twenty-four hours.

This leads to consideration of the question as to how the blood alkalinity is created and maintained in man and herbivorous animals. Carnivorous animals obtain their sodium carbonate from the interaction of ammonium

carbamate and sodium chloride; in man and omnivorous animals this occurs completely only under such conditions as prolonged hunger. The most common factor in alkalization in man and the herbivora is the oxidation of the alkaline salts of organic acids; potassium and sodium salts, especially of citric and malic acids, are contained in leaves, roots, tubers, and fleshy fruits. The potassium citrate and malate in such vegetables are converted into sodium salts by the sodium chloride contained in the meals. These salts, however, are lacking in meat and all kinds of seeds, which indicates the importance of a well-balanced diet. It is a very important and significant fact that milk contains sodium citrate; otherwise a baby would suffer from acidosis from the first day of its life.

Proteins, however, which form such an important part of present-day diet, favour a state of acidosis. Their sulphur contents appear in the urine as sulphuric acid and ester-sulphuric acid, and their phosphorus contents as acid phosphates. Therefore the physiological laws of a correct diet are observed by the usual practice of supplementing a dish of meat with potatoes, or cabbage and fleshy fruits. When, however, the meals consist of an excess of meat, beans, and bread, without any green vegetables or fruits, there would be no calcium retention, and ailments, such as gout, might gradually arise. It would definitely be a mistake to employ calcium chloride in such a case.

With animals, such as cattle and horses, which feed chiefly on hay, the use of calcium chloride produces excellent results by favouring growth, fecundity, and health. The normal dose of calcium chloride has been inferred from physiological laws, and fixed at 0.04 gram of the crystallized salt to 1 kilo of body weight, or 0.02 gram of the anhydrous salt. Hay contains alkaline salts of citric, malic, and other organic acids, which provide for calcium retention and counteract the acidosis produced by calcium chloride.<sup>1</sup> Therefore, when due consideration is given to the usual diet of man, calcium lactate is preferable to calcium chloride, since it does not favour acidosis, and far superior still to calcium lactate is the double salt of calcium and sodium lactate (Wulffing), since it favours calcium retention by being oxidized into carbonate. Many physicians have used it with most excellent results.

Is the calcium content of the blood a reliable index? There is still considerable adherence to the view that a deficiency of lime in the system can be recognized by determining the amount of calcium in the blood. It has, however, been proved by various workers, that this is decidedly unreliable, and Stewart<sup>2</sup> was right in calling that index unsatisfactory. Indeed, it has been commonly observed that, in various diseases which readily respond to calcium therapy, the blood calcium was normal, or higher than normal, and not lower, as one would expect. In other cases, again, the calcium index of the blood was below the normal. In short, the evaluation of the calcium content of the blood is not a sure guide for the application of calcium therapy. Such an examination of the blood calcium is, moreover, unnecessary, even if there is a developing disease which cannot be definitely diagnosed, since calcium can do no harm in any case, and frequently acts as a prophylactic.

The fact that a lack of lime in certain organs is sometimes coincident with a rise of blood calcium is accounted for when we remember that the calcium stored in the bones can be utilized to fill up deficiencies in other and more vital parts of the body. Since this transfer of calcium takes place through the blood, an increase of blood calcium may be observed in spite of a deficiency of calcium in certain other organs. Sometimes when there is not enough calcium in the food bone calcium will supply the material needed for calcification of tuberculous foci in the lungs, or it may serve to calcify weak arteries and thus increase their power of resistance against a rise of blood pressure. Even the teeth may be called upon to give up part of their calcium in certain cases; hence the suggestion by many women that the birth of each child costs the mother a tooth.

How unreliable an index is the evaluation of the blood calcium has recently been again demonstrated in cases of urticaria undergoing hospital treatment. Because the

blood calcium was found to be normal it was doubted whether calcium therapy would be of any use, and this in spite of the work of Wright and Beitman and the observations of numerous other authorities. Herzfeld and Lubowski<sup>1</sup> observed hypercalcaemia in 100 patients who suffered from neuralgia, chorea, tabes dorsalis, and chronic enteritis, yet calcium therapy has furnished splendid results in cases of neuralgia. Verglano, Looft,<sup>2</sup> and Tschember<sup>3</sup> have observed hypercalcaemia in a series of cases of tuberculosis; Loeper and Bechamp<sup>4</sup> in cases of nephritis, asthma, and pneumonia; Longo<sup>5</sup> in rickets, and Blum<sup>6</sup> in a case of osteomalacia. In all these cases, however, calcium therapy would have produced entirely satisfactory results, in spite of the contrary inference from the state of hypercalcaemia.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## PNEUMOCOCCAL PERITONITIS DURING THE PUERPERIUM: RECOVERY.

THE rarity of the occurrence of pneumococcal infections of the peritoneum would seem to justify publication of a case, especially since recovery ensued.

A woman, aged 24, was delivered of her first child on May 16th, 1927. The labour was conducted by Dr. C. Fraser, who simply eased the head over the perineum with forceps, under light chloroform anaesthesia. The labour was otherwise normal, and the placenta was expelled half an hour after delivery.

On May 23rd, seven days after delivery, the temperature rose to 103.2° F., and the pulse rate was 140. On the following day I was called to see her by Dr. Fraser, and gently brushed over the interior of the uterus with a gauze swab on a holder, but found no retained chorion; the uterus had scarcely involuted at all. I injected an ounce of sterile glycerin through a catheter into the uterine cavity, after the manner of Remington Hobbs. The patient was also given 5 grains of quinine bilydrochloride intramuscularly, and 60 c.cm. of polyvalent antistreptococcal serum, since the case looked like a streptococcal infection; but the report by Dr. H. M. Galt on the swab which I took from the cervix was that the film showed Gram-positive diplococci, while from culture were recovered diphtheroids, *Staphylococcus albus*, and a few coliform bacilli.

On May 25th the temperature had fallen to 99.4° F. and the pulse rate to 100, the patient being very comfortable. I contented myself by giving a further 5 grains of quinine and injecting another ounce of glycerin into the uterine cavity. On May 26th in the morning the temperature again rose to 103° F., and the patient complained of severe pains in the lower abdomen. Towards evening the abdomen had become rigid; vomiting had set in, and the pulse was uncountable.

It was obvious that the patient had general peritonitis, and the case looked hopeless. She was given an anaesthetic, and I opened the abdomen, and found the coils of intestine, as also the uterus, tubes, and ovaries, coated with a greenish covering of fibrinous exudate. I let out about two pints of turbid fluid. Three drainage tubes were inserted through the laparotomy wound, one to the right, another to the left, and a third down into the pelvis.

On May 27th her condition was better, although she vomited from time to time. Her pulse rate was 130 and her temperature 101° F. She was pouring out copious fluid through the drainage tubes. Dr. Galt's report of the turbid fluid taken from the abdomen was that the film showed large numbers of pneumococci, while on a trypticar medium an abundant and pure growth of pneumococci was obtained. On receipt of this report the patient was given 10 c.cm. of Pané's antipneumococcal serum.

On May 28th her condition had further improved; she ceased vomiting, her bowels acted, and she began to take nourishment. She was given another 10 c.cm. of Pané's antipneumococcal serum. On May 29th a further dose of the serum was injected; pus was coming freely through the drainage tubes.

From this point her recovery was uninterrupted, although her temperature did not become normal until the end of June. An abscess in the right forearm, which also proved to be pneumococcal, was opened on June 16th. She is now in good health.

I have ventured to report this case since pneumococcal peritonitis during the puerperium is rare. In making a search through the literature I have so far found only one case, although there must have been others, no doubt, where a bacteriological examination was not made. This case is reported by Professor C. Monekeberg<sup>1</sup> of Santiago du Chili. His case was fatal, and differs from mine in that pneumococci were found in the swab taken from the cervix;

pneumococci were also found in the mouth of the "sage-femme" who attended the woman in her labour, which may or may not have been the cause of infection. No laparotomy was performed in this case, but the necropsy revealed purulent endometritis, pneumonia, and peritonitis. The pneumococcus was found abundantly in the ascitic fluid, as in my case.

## HAEMORRHAGE FROM THE DEEP EPIGASTRIC ARTERY INTO THE RECTUS ABDOMINIS.

THE following case is of special interest in view of the diagnostic difficulty experienced.

A man, aged 55, was admitted to the Kettering General Hospital with a provisional diagnosis of acute intestinal obstruction. He had continued his work until the morning of the day of his admission to hospital, when he had a sudden attack of pain in the umbilical region; the pain was definitely localized, increasing in severity with each respiration. On palpating the abdomen the left rectus was found to be markedly rigid, and there was also a certain amount of general abdominal rigidity; a definite painful area on pressure was present about the middle of the left rectus. The bowels had acted in the morning before the onset of pain; the abdomen was not distended, and the flanks were resonant. There were repeated attacks of feeling sick, but he was unable to bring anything up. The tongue was furred and the breath foul. The temperature was 98° F., and the pulse 108 (6 p.m.). An enema was given with good results. Operation was postponed, and the patient was kept under close observation. At 2 o'clock the next morning the temperature was 100.4° F., and the pulse 76; pain and rigidity still persisted. At 10 a.m. the temperature was 99° F., and the pulse 80. As the pain and tenderness persisted it was decided to operate. The abdomen was opened in the middle line above the umbilicus, and the middle third of the left rectus was found to be the seat of haemorrhagic effusion with apparently no other pathological lesion. The patient became worse under the anaesthetic, and, although the operation was short, stimulants had to be resorted to twice before he left the table. Death occurred on the fourth day after operation.

At the necropsy the haemorrhage into the rectus was found to have increased. The heart valves were apparently normal, but the myocardium was extremely friable; throughout the arterial system there was what appeared to be an advanced stage of general arterio-sclerosis.

## TINEA INTERDIGITALIS PEDIS.

IN his recent address on ringworm and its treatment Dr. J. M. H. MacLeod mentions (*British Medical Journal*, April 21st, p. 656), among other varieties of ringworm affection, a type of "eczematoid ringworm of the extremities"—otherwise tinea interdigitalis pedis. Without discussing the question of which particular variety of epidermophyton is responsible for this most discomfiting and intractable affection, I desire to question the wisdom of part of the treatment recommended for it by the lecturer—namely, the advice to soften the skin by soaking in salt water or wading in sea water; and perhaps also the choice of medicament.

This affection manifests eczematous characters, and always appears to be readily curable in cold climatic conditions, but recurs somewhat unaccountably in the summer time, or more particularly under tropical conditions of living, when it is then most intractable. Any such conditions which result in undue moisture of the skin between the toes induce a fresh outbreak of symptoms, initiated by intense irritation and followed by vesication, painful fissures, and the appearance of white sodden patches of thickened epidermis between and beneath the toes. Moisture and warmth are the two factors necessary to promote development of this fungoid affection, which seems able to remain unnoticed in the epidermis for months before reappearing. Salt-water bathing is harmful, because it usually leads to moisture remaining between the toes despite careful drying, and sea wading especially so, because in addition it means spreading of the toes, with consequent causation of fissures made needlessly worse than they otherwise might have been. I would certainly dissuade any sufferer from sea wading or walking barefoot on a sandy beach if previous experience had not already made him wise. It has been demonstrated to me that a week's indulgence of sea bathing in the summer can precipitate the reappearance of this affection after

<sup>1</sup> *Gynécologie et Obstétrique*, Tome vi, 1922, No. 1.

having been entirely absent for many months during the winter, and in spite of the fact that a mildly antiseptic ointment—namely, 2 per cent. yellow oxide of mercury in vaseline—was used between the toes after careful drying, and the socks were sterilized by soaking in lysol solution. I have found that (a) dusting powders used with the idea of drying the skin between the toes are useless to prevent reappearance of this affection, whilst antiseptic powders continually used on sensitive skins lead to irritation, which it is most desirable to avoid; (b) any spirituous preparation, including salicylic acid in spirit, is unnecessarily severe, and, furthermore, aggravates cracking and shedding of epidermis; (c) salicylic acid ointments tend to a similar result.

After an exhaustive trial of many preparations I have found that the most satisfactory medicament is an ointment of 2 to 3 per cent. chrysarobin in vaseline, applied sparingly but often, after careful washing and drying of the toes. It is at the same time essential to excise the top from all vesicles, remove all loose epidermis, and clean up the edges of ulcers. This ointment soothes and softens the irritated skin, maintains its elasticity, precludes the penetration of undue moisture, induces healing without any aggravating effect, and the drug appears satisfactorily to penetrate the epidermis and kill the fungus proliferating in its substance. Moreover, its continued use renders soft and pliable the tough horny skin of the sole of the foot adjacent to the base of the toes, which is very necessary to promote the healing of ulcers, so prone to occur in this area: it seems probable that here also is the source from which there develops a reappearance of the affection months after its apparent cure has been effected.

### CLINICAL AND SCIENTIFIC PROCEEDINGS.

#### LEICESTER AND RUTLAND DIVISION.

##### NEW DEVELOPMENTS IN PHARMACOLOGY.

In a lecture given to the Leicester and Rutland Division on May 1st, with Dr. E. L. LILLEY in the chair, Professor W. E. DIXON discussed the trend of thought in the art of therapeutics. He deplored the lack of pharmacological initiative and research in this country, as a result of which for many years there had been dependence for new drugs and treatments on Germany, France, and America. He then gave a detailed description of two drugs which had recently come into prominence.

##### *A New Type of General Anaesthetic.*

The first, a tribrom-ethyl alcohol, was a new general anaesthetic known by the trade name of "avertin," the action of which had been determined precisely by Straub. It was a solid substance which at body temperature dissolved only to about 3 per cent. in water, but if more concentrated solutions were required it could be employed in a suspended form. To produce general anaesthesia in a patient weighing 11 st. about 10 grams of this substance was administered per rectum; this was rapidly absorbed—indeed, considerably more rapidly than water or saline solution—and the patient was anaesthetized and ready for the surgeon within ten minutes. With this anaesthetic operations had been performed lasting two hours or more without pain or any subsequent discomfort to the patient, and a considerable clinical literature was already available. At first, accidents happened after using it, but since the mechanism of its action had been better understood these had entirely disappeared. The drug after absorption acted on the central nervous system like the commoner anaesthetics, but within a few hours it was completely broken up in the body, the bromine being converted to sodium bromide. With an anaesthetic dose of 10 grams about 11 grams of sodium bromide was produced, and such an amount led to sleep lasting perhaps for thirty-six hours after the operation had been completed. The proportion of bromide excreted depended upon the amount of sodium chloride in the blood, and varied with it; it was well known that under normal conditions when the chloride

was constant the excretion of bromide was very slow, and, after a single dose, could be detected in the urine for several days. It was a simple matter, however, to get rid of this excess. In the case under consideration after the operation had been completed the excess of bromide should be eliminated by increasing the excretion of chlorides; this was effectively achieved by injecting from 5 to 10 grams of common salt, suitably diluted, into the rectum. One objectionable feature of this form of anaesthesia, as indeed of other forms of anaesthesia, was the production of some degree of acidosis. To combat this it was advisable to dose the patient before operation with sodium bicarbonate. The great advantages of this method of producing anaesthesia were obvious. The ease and certainty of producing the desired effect in a short time and for a long period, the absence of discomfort during administration, and the general comfort of the patient for several hours after the operation was completed, were some of them.

##### *Specific Therapy in Septicaemia.*

In discussing specific therapy Professor Dixon paid considerable attention to mercurochrome, the sodium salt of mercury dibrom-fluorescein; it contained about 26 per cent. of mercury and 21 per cent. of bromine, and had a molecular weight of 750, which was a molecule so large as to be approximating to the colloidal state in solution. The samples obtainable on the open market varied considerably in their toxicity; many experiments showed that rabbits succumbed to an intravenous injection of 10 mg. per kilo of body weight, but Professor Eyro had stated that he had a preparation which, while possessing therapeutic efficiency, did not kill rabbits in doses of 25 mg. per kilo. The lack of uniformity in many of the experiments with this compound might not be unconnected with this variability. Mercurochrome was non-astringent and non-irritant. Its antiseptic action in the test tube was high; thus *B. coli* and *Staphylococcus aureus* in urine were killed by concentrations of 1 in 1,000 within a minute. This fact had led to the prevalent view that it acted as a cure by directly destroying micro-organisms; this might be true in the case of local infections. Thus it might account for the cure of bladder troubles used in a strength of 1 in 1,000; or for posterior urethral injections (1 in 400); employing a catheter, or for local applications to the vagina in gonorrhoea where sometimes as strong a solution as 1 in 25 was required. Mercurochrome was given, however, mainly by intravenous injection to effect a cure of general infections, and remarkable clinical reports had been published by many different clinicians. Why so large a number of patients were cured after such injections was not understood. It had been suggested that the beneficial results were due to colloidal shock reaction, and in favour of this was the fact that the compound was rapidly excreted by the bile, and that no bactericidal properties were shown by the blood, the bile, or the joint fluids in those cases in which arthritis was a symptom of the infective process. Moreover, occasionally the injection was followed by a sudden rise in temperature, succeeded by a rapid fall and associated with other symptoms of mild shock, as in the gold treatment of tuberculosis. Clearly, then, the element of shock might not be without its significance. The lecturer, however, regarded the bacteriological findings of little importance in appraising its therapeutic value when compared with the findings of the physician. Several substances which produced a cure of specific disease had apparently little direct action on the causal agent. This was true, to mention only one example, for the complex-dye substance prepared by the Bayer Laboratory and by Fournau, which effected a cure of certain forms of trypanosomiasis. Ehrlich at first discarded atoxyl as useless in syphilis because its direct action on protozoa was negligible, though when its curative properties came to be recognized it formed the starting point from which salvarsan was ultimately evolved. Experiments made on animals inoculated with the pneumococcus or anthrax bacillus had shown that mercurochrome produced a considerable percentage of cures—50 per cent. or more—but even these results were not yet conclusive, since, although they had been confirmed, they had also been denied. Clinical reports were more definite and impressive. They

showed that in a large proportion of cases of septicaemia in which a pure culture of streptococci could be obtained from the blood injections of mercurochrome were followed by a cure. Young had reported the clinical results in 173 cases of septicaemia treated with mercurochrome, with a cure in 63 per cent. The papers by Dr. Young and his colleagues showed so many remarkable cures that the use of this remedy deserved a more extensive trial in this country. In septicaemia mercurochrome was given intravenously as a 1 per cent. solution in doses beginning with 2 or 3 mg. per kilo; from one to five doses at intervals of four to five days might be required to effect a cure. In desperate cases of septicaemia or other infections where the patient might die in a day or two 5 mg. per kilo, or even more, might be given. The objectionable results which might occur were stomatitis and, with large doses, transient albuminuria, though the latter effect was rare. The weak point about mercurochrome therapy at the present time was its variability in toxicity, and, therefore, possibly in its therapeutic efficiency; for this reason the maker should guarantee the molecular weight and the percentages of bromine and mercury, and should state its toxicity. Nevertheless, mercurochrome was not a dangerous drug to use, and its many users in other countries were convinced of its merit.

#### GUILDFORD DIVISION.

##### CLINICAL PATHOLOGY AND GENERAL PRACTICE.

At a meeting of the Guildford Division on May 3rd, with Mr. H. B. BUTLER in the chair, Dr. H. C. MATSON gave an address on some aspects of clinical pathology as an aid to the practitioner.

Dr. Matson first emphasized the great importance of the total white count in addition to the differential count in determining whether a morbid condition was septic or chronic. Both results should be combined to avoid wrong conclusions. Thus a differential count of 44 per cent. lymphocytes might indicate a slight condition of no importance, but if the total white cell count was 15,000 to 20,000 per c.mm., the probability was that an early lymphatic leukaemia existed; thus by omitting the total count an important diagnosis might be overlooked. It was necessary to remember that a physiological leucocytosis occurred after food; if a series of counts was required, the determinations should always be made at the same hour each time. An inquiry whether the patient was on a full diet or not was important. In the anaemias a complete white count was as necessary as a complete red count, since a leukaemia might easily be missed if the examination was limited to the total number of red cells, the haemoglobin, and the colour index. This was especially true of the acute leukaemias, as the process was often so rapid and the physical signs were practically absent, though the patient might be dead in a week. Passing to Vidal tests, the lecturer warned against paying too much attention to the leucopenia in typhoid infections, since a leucocytosis might often follow. Vidal tests should not be performed before the tenth day, since the agglutinins were not in evidence previously. For an earlier diagnosis than this a blood culture was required, and in the third week of the disease the urine and faeces should be examined. Patients vaccinated with T.A.B. might retain the agglutinins in their blood for so long as thirty years, and a period of seven years was quite common. In those who had suffered from typhoid and paratyphoid infections the blood might retain its agglutination power for the rest of life. It was probably always necessary to inquire whether the patient had suffered from these infections or had been vaccinated with T.A.B. They showed, as a rule, an agglutination of low titre, which should arouse suspicion. If the leucocytosis accompanied a positive Vidal reaction, a secondary infection superimposed on the original typhoid one should be suspected, or a developing typhoid cholecystitis, or perhaps peritonitis. It had been found that patients with endocarditis might give a positive reaction in low dilutions, and it had been asserted that miliary tuberculosis might act similarly. Controls should always be employed. Dealing with van den Bergh's reaction, Dr. Matson explained its uses in determining the cause of jaundice due to hepatogenous

conditions such as stone in the common bile duct, or neoplasm, and in toxic and haemolytic jaundice, where there might be a direct reaction, or a bi-phasic reaction where an obstructive and a toxic process were combined. He added that the test was very valuable in latent jaundice, and in some cases of pernicious anaemia. In blood grouping for transfusion it was very important to match the recipient's serum against the donor's red cells after the grouping process had been performed. The blood calcium estimation was becoming increasingly popular, especially in thyroid deficiency diseases. The value was low as a rule in skin diseases, and might be very low in cases of colitis; it was probably very high in arthritis deformans. The blood urea test was of great value to the surgeon as indicating the condition of the kidneys, and whether there was much impairment of renal function, especially in cases of enlargement of the prostate. Blood sugar tests were of little value if taken without reference to the time of day and to previous estimations. A glucose tolerance curve should always be constructed, commencing with the result obtained during a fasting period. Glucose should then be given, and the dose be repeated half an hour and one hour afterwards. In this way the patient's tolerance might be determined at once and the necessary dieting prescribed.

## Reports of Societies.

### INTRAVENOUS TREATMENT OF VARICOSE ULCERS.

At a combined meeting of the Sections of Dermatology and Surgery of the Royal Society of Medicine, on May 16th, with Mr. R. DAVIES-COLLEY in the chair, a discussion was held on the treatment of varicose ulcers by obliteration of varicose veins by injection.

The CHAIRMAN, introducing Professor Sicard, who initiated the method in 1916, mentioned that obliteration of veins had been attempted fifty years ago by the injection of ferric chloride, but the method had been given up because it had proved unsafe. He added that Professor Sicard and his colleagues had now removed the danger from this intravenous injection method, and had rendered it of great practical value.

Professor SICARD reviewed the factors concerned in the production of ulceration in the lower limb. The influence of varix, age, heredity, and derangements of the endocrine system were discussed, and the analogy between the action of pituitary extract on the veins and adrenaline on the arterioles was mentioned. These various factors caused weakness of the walls of the veins and of the supporting perivascular tissues, with incompetence of the valves of the veins. Syphilis alone or associated with any of these other factors was a fairly common cause of ulceration. Local factors, such as trauma, intrapelvic pressure, phlebitis, infection, and prolonged standing, played an important part. Professor Sicard classified ulcers in the lower extremity in four therapeutic groups: (1) Post-phlebotic ulcers with oedema of the limb. This type was certainly not suitable for injection, the only lines of treatment being rest, massage, and support. (2) Dirty serpiginous ulcers of long standing, with marked local dystrophy, were also unsuitable for injection, and could only be treated by rest, disinfection, vaccines, light, and surgery. (3) Ulcers with moderate or mild local disturbance, usually preceded by local dermatitis, were very much improved by sclerosing injections of the veins combined with local applications. (4) Mixed syphilitic and varicose ulcers, which were cured by antisyphilitic treatment combined with local obliterative injections. With the aid of microscopic drawings the pathology of chemical venitis and thrombosis was described, and the firm adherence of the clot to the endothelium was demonstrated. Professor Sicard said that with his colleagues Drs. Forestier and Gavrier he had demonstrated the passage of fluids from the superficial to the deep veins of the limb on slight muscular contraction, by means of the injection of opaque solutions such as lipiodol or sodium iodide into the superficial veins, followed by stereoscopic

x-ray photographs. These photographs were shown, and they illustrated clearly the passage of the lipiodol into the deep veins on slight muscular movement. He therefore always performed the injection in the supine position, instructing the patient to keep the limb absolutely still and flaccid. In this way the injected fluid remained in the superficial vessels and produced a much better thrombosis. Numerous lantern slides were shown of patients before and after treatment, to indicate the marked improvement in the appearance of the limbs and the healing of the ulcers. Examples of venectasia, extending to the pubis and upper abdomen, were also shown. Professor Sicard pointed out that these cases were not suitable for injection, since there was often obstruction to the deep veins, and also because they were difficult to sclerose owing to the rapid stream of blood through them. It was in these cases that accidents were liable to happen. A 20 to 60 per cent. solution of sodium salicylate in water was the most satisfactory; he gave 2 to 3 c.cm. in one dose, and he injected all the veins immediately proximal to the ulcerated area. The number and frequency of the injections had to be adapted to the individual case. Other solutions, containing quinine and urethane, sodium citrate, glucose, as well as hypertonic saline, had been used with less success. In conclusion, Professor Sicard said that the improvement was most marked in the early cases; when eczema was a predominant feature it rapidly improved. No complications had been encountered, and relapse was rare; when this did occur a second course of injections was invariably successful.

Mr. TWISTINGTON HIGGINS based his observations on 200 completed cases of varicose veins, in thirty-five of which there was active ulceration. He had used sodium salicylate, quinine and urethane, and 50 per cent. glucose, and found that sodium salicylate and the quinine solution were equally satisfactory. Discussing the parts played by trophic disturbances, trauma, and infection in the pathology of varicose ulceration, he said that the best results were obtained by the injection method, in cases in which the trophic element predominated, and the poorest results in those cases presenting a great deal of infection. The speaker considered it most important to disinfect and clean the ulcer before commencing treatment, because any risk of embolism was increased in the presence of a septic focus. He commenced injection well above the ulcer, and noticed that, owing to the great dilatation of the vessels usually present, many injections were necessary to produce sclerosis, and that there was a greater risk of local necrosis since the vessels were usually very thin-walled and near the skin. He had not met with a case of embolism, but from the investigations of Professor Sicard and his own observations on histological examination of a vein after injection, he thought that the risk was very small, because the clot of irritative endovenitis was very adherent. He mentioned that Professor Sicard had treated 2,960 cases without the occurrence of embolism. To remove any possible risk of this complication he emphasized the importance of preliminary treatment of septic foci and the avoiding of excessive muscular movements for about three weeks after an injection. Mr. Higgins felt strongly that the greatest use of sclerosing injections lay in the preventive treatment of varicose ulceration. Patients were much more ready to submit themselves to the injection treatment at an early stage than they were to undergo an operation. The out-patient department of hospitals bore testimony to this procrastination, patients often only seeking treatment when a large and foul seriginous ulcer was present. The pre-ulcerative stage was easily recognizable and the injection of the veins was of the utmost value in aborting the atrophic changes and re-establishing the nourishment of the tissues. The speaker, referring to perivenitis, necrosis, and cases with marked local reactions, said that these sequels were often due to faulty technique, though they sometimes occurred when the solution was injected correctly into the vein. Such complications occurred most often in severe cases, in elderly patients, in thin-walled veins, and in veins over bony prominences, such as the tibia and internal condyle of the femur. He thought that possibly the best treatment for these complications was excision. General toxic symptoms were rarely encountered; complaints of a little giddiness after sodium sali-

cylate were sometimes received, and patients often tasted the quinine soon after its injection. Mr. Higgins had one case of vicarious menstruation after the injection of quinine and urethane. Complete failure, in his experience, was uncommon, and a successful obliteration of the vein could be promised in every case after repeated injections. Secondary dilatations did occur and under dosage produced thickening of the veins without occlusion.

Sir SIDNEY ALEXANDER said that he had used 40 per cent. sodium salicylate solution, quinine and urethane solution, and sodium chlorido solution, but that he had obtained the best results with sodium salicylate. This solution produced a very marked immediate effect, and the thrombophlebitis occurred quickly. Patients, however, often had cramp soon after the injection. Quinine and urethane gave rise to little or no immediate discomfort, but about two or three days afterwards patients complained of pain in the legs, even worse than that occurring immediately after sodium salicylate injection. The speaker objected to the massive doses of glucose necessary to produce effective thrombosis. He used the horizontal position, but placed the patient with the leg hanging downwards for injection of the smaller veins. To prevent leakage, he immediately applied an isinglass plaster to compress the site of injection. Rest and local treatment of the ulcer were also necessary, and a word of warning was given concerning the use of quinine solutions during pregnancy.

Mr. DAVID LEVI reported the results of treatment of 60 cases. Of these 57 were cured, but 3 failed to respond to injections of 66 per cent. glucose. He had had one case of embolus following three injections of 66 per cent. glucose, and another patient had transient pain in the side. Mr. Levi showed microphotographs of the venitis following glucose injection, and pointed out the looseness of the clot. He therefore concluded that quinine solution was better. He had failed to produce experimental obliterative venitis in a rabbit's ear, even after obstructing the blood flow, and he therefore thought it was probable that the thrombosing effect of the injections only occurred in diseased veins.

Dr. GOLDSMITH pointed out that it was important to determine the direction of the blood flow in the veins in the upright position. A backward (centrifugal) flow produced oedema and stretching of the skin, with consequent ulceration. He thought that it was rational to expect that obliteration of such veins would aid the healing of the ulcer. He said that the advantages of the injection method over surgery were that injections could be given in cases of infected ulcer, and that the movement of the limb, allowed during the sclerosing process, played a very important part in the relief of the aching and the oedema. If the veins showed an upward flow they should not be injected, since they were not helping in the production of oedema of the skin. A history of phlebitis was also a contraindication to injection. The speaker only gave one injection at a time, since the height to which the thrombosis extended varied very considerably. He preferred glucose solution, since it was painless, non-toxic, and did not produce local necrosis. Glucose could be sterilized by boiling for half an hour without the production of toxic substances. He used a tourniquet in the erect position to demonstrate the vein, removing it after he had inserted the needle with the patient in the horizontal position.

Mr. R. T. PAYNE said he had treated thirty cases of varicose ulcer with sclerosing injections of quinine and urethane solution. All the ulcers were also treated with calamine lotion, and the patients were allowed to walk about during the course of treatment; all but one case showed signs of healing. He also used a tourniquet and compressed the site of injection for two minutes after withdrawal of the needle, and then applied strapping. The speaker thought that all the cases of local necrosis and perivenitis he had met with were due to this leakage of the solution after injection. He said that not only was there a distal flow in the veins, but that the capillaries shared in this back flow. It was the re-establishment of the capillary circulation which was of importance in the healing of an ulcer, and this could be attained by surgical extirpation of the veins and by firm bandaging, or by obliteration of the veins by injection.

Dr. BECKETT-OVERY said he had performed 500 injections with sodium salicylate. He usually produced six to eight inches of thrombosis, and had very little reaction. Dr. GARY mentioned that toxæmia was the chief factor in the production of varicose veins, since they made their appearance during pregnancy before the uterus was large enough to obstruct the blood return. He also referred to Lloyd's comparison between the characters of the clot in thrombosis and blood clot after bleeding.

Dr. FORESTIER, replying for his colleagues Professor Sicard and Dr. Gaugier, said that the ulcers suitable for treatment by injection were those with moderate dystrophic changes, and these due to syphilis as well as trophic disturbances. Post-phlebitic ulcers and the large dirty serpiginous ulcers were not suitable for treatment. Venectasia of the pubis and abdomen was also unsuitable. He agreed with Mr. Twistington Higgins that the greatest use of the method was in prevention of ulceration. He never used a tourniquet, and had never failed to inject a vein. There was a marked difference between the pathological histology of chemical venitis and infective phlebitis. He thought that at present it was an open question whether there was any difference between the thrombus produced by glucose and that produced by the other solutions, but he added that the only fatal cases reported in the literature followed the use of glucose. Necrosis of the skin had not occurred since sodium bicarbonate had been discarded. In conclusion, he emphasized the importance of a thorough examination of the patient before treatment, paying special attention to the blood pressure and to the examination of the urine for albumin.

### SKELETAL METASTASES IN CARCINOMA.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on May 4th, with Dr. M. R. J. HAYES in the chair, Mr. F. J. HEURY reported a case of extensive carcinomatosis of the skeleton in a woman, aged 49, who had first noticed a lump in the left breast about a year previously.

Mr. HEURY said that six months later this lump began to ulcerate through the skin, and the patient began to suffer from severe rheumatic pains in the back and about the shoulders. She was in an extremely miserable condition, being very cachectic and scarcely able to move. A large fungating mass was present in the upper part of the left breast, and enlarged glands could be felt in the left axillary and supraclavicular regions. X-ray examination showed multiple areas of rarefaction and erosion in the spine, ribs, and pelvic bones. There was pronounced angular deformity in the lumbar region, due to collapse of the bodies of the eleventh and twelfth dorsal, and possibly of the first lumbar vertebrae. The general appearances of the vertebral column were very unusual; they were attributed to decalcification and in some cases to condensation, probably brought about by compression. Secondary deposits were also demonstrated in the humeri, scapulae, and femora. A blood examination was made, but revealed none of the abnormalities described by Piney as occurring in diffuse carcinosis of the bone marrow.

Dr. M. R. J. HAYES said that he had never seen such extensive metastases as in this case. He discussed the probable path of infection, and suggested that it might be a secondary infection through the blood stream. He referred to the care taken in America to perform a complete examination before an operation in cases of carcinoma of the breast. The condition in which he had found secondary deposits most common, and occurring at a very early date, was carcinoma of the prostate.

Mr. WALTER C. STEVENSON thought that one reason why surgery and radiation treatment succeeded in cancerous cases was that when the growth was removed the power of the patient to resist cancer was strengthened.

#### Surgical Uses of Radium.

Mr. WALTER STEVENSON, in a paper on some surgical uses of radium, briefly summarized 247 cases treated during the year 1927. Of these, 127 patients suffered from malignant disease and 120 from non-malignant conditions; his communication dealt chiefly with the latter. He suggested

that after cancerous cases had been treated the effect of radium treatment of cases met with in ordinary surgical or medical practice might well be investigated. He had found that prolonged radiation with small amounts of radio-active material appeared to have a pronounced effect in promoting the absorption of inflammatory products, entailing the period of sepsis, and relieving pain. He instanced the case of a large swelling in the neck which disappeared with mild radiation, the amount of pus formation being minimal. A case of chronic otorrhoea of four years' standing following a mastoid operation cleared up within three or four weeks of radiation treatment for seven hours. Immediate relief of the intense pain and rapid healing followed mild radiation for five days of an ulcer of the leg of about fifteen months' duration following a compound fracture. The consolidation of a united fracture of the femur in a rickety child appeared to be greatly hastened by radiation. He stated that with some of his colleagues radiation appeared to be the routine method of treating tuberculous peritonitis; certain of these cases had been treated after exploratory laparotomy when very extensive disease had been found. Mr. STEVENSON thought it probable that similar results would be obtained by  $x$  rays, but he added that the control of the dosage of radium was much better than in the case of  $x$  rays, and he instanced a case of recovery from tuberculous lung trouble which he had radiated without intermission for seven months.

Dr. M. R. J. HAYES believed that in cases of tuberculous peritonitis laparotomy was the best treatment; he was always chary of applying radiation to acute inflammatory conditions. In cases of cervical adenitis, if any of the glands contained pus, the patients should not be treated by radiation until an operation had been performed and the pus let out.

Dr. R. STURMF said that the indications for the use of radium treatment and treatment by  $x$  rays were not sufficiently known. It was possible by  $x$ -ray treatment in most cases to get as good results as were given by radium. In cases of keloid he preferred to use radium, and in cases of malignant disease of the mouth and oesophagus he employed combined treatment by radium and  $x$  rays. He had treated cases of tuberculosis of the larynx, boils, erysipelas, and actinomycosis successfully by  $x$  rays.

### MANCHESTER PATHOLOGICAL SOCIETY.

At the annual meeting of the Manchester Pathological Society on May 9th, with Dr. T. A. GOONFELLOW, the incoming president, in the chair, Professor J. S. DUNSTON gave a demonstration of venomous and non-venomous snakes. The mechanism of erection of the fangs and the action of the temporalis muscle in emptying the poison-secreting gland in venomous snakes were explained. The speaker added that the ordinary teeth were prehensile only, the victim being swallowed whole. The muzzle of the prey was swallowed first, since ingestion was easier in this way than in any other. Owing to the absence of mastication the opening of the trachea was placed far forward in the mouth, choking of the snake during deglutition being thus prevented. The venom contained a neurotoxin, as well as a proteolytic enzyme and a haemolytic body; the poisons were, to a large extent, specific. Mr. F. H. WESTMACOTT showed specimens and photographs from a case of chronic hypertrophic pulmonary osteo-arthritis, one of the first examples of this condition to be reported. Mr. R. D. MOTHERSOLE showed a specimen of a congenital buccal cyst, about the size of an orange; it was found lying on the mother's perineum after delivery, with which it had caused some interference. The pedicle had been attached between the lower lip and the jaw of the child, who was alive and well. Professor SHAW DUNN showed specimens of ulcers of the oesophagus, among them two examples of decubitus ulcers of the pharynx, caused by the pressure of the cricoid cartilage against the vertebral column. In one case this pressure had been due to a marked anterior curvature, the result of spondylitis. Dr. C. POWELL WHITE demonstrated a number of microphotographs illustrating various points in the histology of tumours, including an adenoma and an adenocarcinoma of the rectum from the same patient, and also an adenocarcinoma arising in the centre of an adenoma.

## Rebels.

### CLAUDE BERNARD'S "INTRODUCTION."

MR. H. COPLEY GREENE'S translation of CLAUDE BERNARD'S *Introduction to the Study of Experimental Medicine*<sup>1</sup> will help to make English readers acquainted with a work that should be in the hands of everyone who is engaged in medical research. The translation is excellent, and is preceded by an appreciative account of Claude Bernard by Professor Lawrence Henderson of Harvard and Paul Bert's article written at the time of Bernard's death. Although the *Introduction* made its first appearance in 1865 its value has not diminished in the lapse of years; indeed, it is difficult to believe that it will ever be out of date, because it expounds in a masterly way the fundamental principles of experimental research that hold for all time. It is, moreover, no mere philosophical dissertation, but a thoroughly practical guide to the research worker, explaining how discoveries have been and are to be made. Claude Bernard is insistent on the practical aspect; he sets aside theoretical questions of deduction and induction as unprofitable, and notes that although the Baconian induction has been made the foundation of all scientific philosophy, Bacon himself did not understand the experimental method; the hapless attempts that he made sufficiently prove it. Great experimenters appeared before all precepts of experimentation, as great orators preceded all treatises on rhetoric; Galileo and Torricelli admirably practised the experimental method which Bacon could never use, and it is the practice of experiment that Bernard explains in his book.

The need for a work of this kind at the present time is referred to by Professor Henderson. He points out that in the composition of modern scientific literature it is the custom to adopt a formal, rigid, and impersonal style which affords no insight into the personality and behaviour of the writer behind the printed page. The same is true of lectures; they are formal, logical, and impersonal. Yet what the novice in experimental research requires is an understanding of the working of the mind of the great investigator, and this is at the present time practically shut out from him; he has to initiate himself into mysteries which no one will explain to him. Of the real disadvantages resulting from this defect Claude Bernard has no doubt; he considered that the genius of inventiveness might be seriously diminished, or even smothered, by a poor experimental method. An inventive spirit and aptness of mind cannot be imparted by any means, but a good method enables such faculties as we possess to be turned to good account.

In Claude Bernard's *Introduction to the Study of Experimental Medicine* we are shown what are the essentials of a good method, and we have a vivid picture of himself at work by one of the most intelligent of modern scientists—a man of genius and a great physiologist. The numerous examples that he gives of his own experimental physiological investigations form an extremely instructive chapter, in which the working of his mind is portrayed in every detail and stage of the process—from the first inception in some, often chance or trivial, observation or hypothesis, and along lines often singularly circuitous and unexpected, up to the final goal of some important discovery.

The book is unique; there is no other like it, and apart from its scientific value it has literary merits which, at the time of its appearance, gained the applause of the French Academy.

### FUNCTIONAL REPRODUCTIVE DISORDERS IN WOMEN.

THE book on the functional disturbances of the female reproductive system<sup>2</sup> by Professor GASTON COTTE is designed to show what can be done in restoration of function, and does not concern itself with those conditions, such

as cancer, that call for radical treatment resulting in destruction of function.

Operations such as salpingectomy are not discussed, but those such as salpingostomy, which have for their object the restoration of function in a tube sealed by inflammation, are included. Similarly hysterectomy as a method of treatment for non-malignant conditions does not come within the author's theme, save in so far as he is concerned to advocate in women before the menopause the subtotal operation, with conservation of at least one ovary, when it is impossible to preserve the integrity of the reproductive tract. He has a very clear impression that the after-effects of this method are much less troublesome than those of the more radical operation.

The first, and much the longest, chapter is devoted to menstruation and its disorders, opening with a section on the sex cycle in the mammalia, which, taken as the biological foundation of the menstrual cycle in women, is considered in detail. In view of the author's purpose a full account of the physiological aspects and meaning of this function is given before going on to its disorders. These latter are confined to absence and deficiency, excess and irregularity of menstruation, dysmenorrhoea being considered under disorders of innervation. Treatment by medical means, especially organotherapy, and by physical and surgical procedures is discussed. He decries the excessive use of the curette, and in this plea will find much support. When, however, he proceeds to advocate various interventions on the ovaries largely based upon theories which are as yet incompletely established, he is on much more contentious ground. Resections of portions of ovarian tissue are advised, and it is suggested that if one ovary is found to contain atretic follicles and no corpora lutea, homoplastic grafting from the other should be practised. Many will hesitate to follow him in adopting speculative procedures of this kind, even if, as he points out, an application of radium may be tried in the event of a recurrence of symptoms. The next chapter covers disordered sexual relations—dyspareunia, vaginismus, and frigidity—and is followed by another on sterility and disturbance of embedding of the fertilized ovum, leaving aside the other disorders of reproduction during pregnancy, parturition, and the puerperium as being more particularly the concern of the obstetrician. Chapter iv is concerned with leucorrhoea and disordered secretion; chapter v with vascular disturbance; chapter vi with disturbances of innervation. The final chapter treats of ovarian insufficiency and the disorders consequent on castration. We doubt, however, if the method of treatment of dysmenorrhoea and "pelvic neuralgias" by division of the anterior hypogastric nerve of the sympathetic plexus after a deep dissection will meet with acceptance.

Our criticism of the book is that, though the author has set out with an excellent purpose, he has allowed his enthusiasm for avoiding mutilation and needless destruction of function to lead him to advance procedures which are unsupported by adequate experience of results.

### THE PNEUMOTHORAX AND SURGICAL TREAT- MENT OF PHTHISIS.

THE pneumothorax treatment of pulmonary tuberculosis is so important, and still so new and therefore subject to revisions and improvements, that everyone interested in it must be grateful for a second edition<sup>3</sup> of a book which has already become the standard authority on pneumothorax treatment in this country. In his preface Dr. CLIVE RIVIERE points out that the original fourteen chapters have grown into nineteen by the addition of separate chapters on such subjects as the reduction of adherent pleura, pleural contraction and its effects, the duration of treatment and its termination. In addition, such subjects as the division of pleural adhesions, small-volume pneumothorax, selective collapse, oleothorax, and pneumothorax in childhood have received separate and special attention. But what distinguishes the second from the first edition most prominently is the addition of a second part dealing

<sup>1</sup> *An Introduction to the Study of Experimental Medicine.* By Claude Bernard. Translated by Henry Copley Greene, A.M. New York and London: Macmillan and Co., Ltd. 1927. (Med. 8vo, pp. xix + 226.)  
<sup>2</sup> *Les Troubles Fonctionnels de l'Appareil Génital de la Femme.* Par Gaston Cotte. Paris: Masson et Cie. 1928. (Sup. roy. 8vo, pp. 570; 116 figures, 60 fr. sans majoration.)

<sup>3</sup> *The Pneumothorax and Surgical Treatment of Pulmonary Tuberculosis.* By Clive Riviere, M.D. (Lond.), F.R.C.P. Second edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1927. (Cr. 8vo, pp. xxii + 311; 16 plates. 10s. 6d. net.)

with the surgical treatment of pulmonary tuberculosis. The author has, of course, avoided those technical and operative details which must inevitably belong to the sphere of the surgeon, and he has confined himself to giving a general survey of the subject for the benefit of the practitioner who, in the interests of the patient, ought to know the indications and chances of success of operative intervention. It is interesting in this connexion to read that "in the estimation of the Matsons and Bisaillon, one-third of the 'no free space' cases, and one-third of the cases of ineffective partial collapse, are suitable for thoracoplasty, and should have this chance offered to them."

#### PULMONARY TUBERCULOSIS.

Dr. G. T. HENRY's little book *Pulmonary Tuberculosis* is intended for the senior student, the post-graduate, and the general practitioner. The first thing that strikes one about it is the peculiar arrangement of the subject matter. The first chapter is headed "Diagnosis"; then come the usual chapters on pathology, symptoms, physical signs, and x-ray examination. Instead of these being followed by a chapter on diagnosis, the author has inserted special chapters on pleural effusion and fibrosis; and when diagnosis is considered, the two chapters devoted to it, headed "Evaluation of evidence" and "Differential diagnosis," are separated by a special chapter on tuberculosis in children. It is to be hoped that in a future edition a more logical order will be arrived at. Apart from this fault of structure, the book is remarkably good; it is clear, direct, and dogmatic, as a popular textbook should be, and is illustrated by some very useful diagrams. We note the inclusion of the old error, copied from one textbook to another for the last forty years, that the *Mycobacterium tuberculosis* is decolorized by alcohol. It is really time that this was given up; it is quite impossible to distinguish the saprophytic acid-fast from the tubercle bacilli by morphological and staining methods, and this should be taught authoritatively.

#### RARE DISEASES OF VERTEBRAE.

Dr. ANDRÉ LÉRI's volume on affections of the vertebral column\* may be taken as a sequel or second part of his book, *Études sur les affections des os et des articulations (colonne vertébrale exceptée)*, which also appeared in 1926, and was noticed in our issue of June 18th, 1927 (p. 1106). These "études," like those which formed the other volume, are all reprints from French journals, in many of which other authors have collaborated, some of whom are highly distinguished, such as Dr. Pierre Marie. The book is divided into five parts, the titles of which will give a clue to its subject matter. These are: I, Anomalies and "troubles" (that is, disorders) of development; II, Traumatic affections; III, Ankylosing disorders of the spine; IV, Localized vertebral rheumatism and its consequences; V, Miscellaneous affections. Of these, the first occupies more than one-third of the book, and includes interesting and often rare cases of maldevelopment, such as sacralization of vertebrae, lumbalization of sacrum, spina bifida, and various conditions which radiography has brought to the front of late years. Parts III and IV, on ankylosing diseases and rheumatic affections, occupy most of the rest of the book. Pott's disease is only referred to in a few pages in Part V on "Pott's" infantilism, in which will be found some interesting observations of cases of severe kyphosis, in which, as is familiar to many of us, there is some degree of arrest of sexual and general development.

Such a volume as this, and its fellow, is valuable as a work of reference, in which the practitioner who has come upon an unusual case may find a record of others of a similar kind, and some hints on their pathology and treatment. In general, however, Dr. Léri lays much more stress on pathology than therapeutics, for no descriptions of

operations or apparatus will be found in this work. Dr. Pierre Marie, who has written the preface, welcomes this book, indeed, as an attempt made by a physician to annex a new territory in a domain which hitherto has almost entirely belonged to surgery. Those who annex, or try to annex, their neighbours' possessions are apt to get into trouble, and Dr. Léri must not be surprised if surgeons fail to admit his claims, since he has not made them good by cures without the help of surgeons. Indeed, in the case of spina bifida with incontinence of urine, Dr. Marie has to admit that the collaboration of a surgeon has been needed to achieve good results.

#### AYURVEDIST MATERIA MEDICA.

Mrs. K. M. NADKARNI, the author of a well-known work on Indian plants and drugs, has issued what appears to be a very complete *Indian Materia Medica*—that is to say, a materia medica on Ayurvedist lines. The book will be of use to those who take an interest in native Indian matters, since it gives an insight into one of the more favourable and practical aspects of Ayurvedist medicine. Being restricted to Indian drugs its scope is necessarily limited in some slight degree, there being, for example, no mention of digitalis and streptococcus. The author, however, does not intend that his book shall replace the British materia medica, but that it may be used side by side with the latter. He hopes that his work may encourage the employment of the drugs prepared in the native bazaars, which are vastly less expensive than imported drugs, and employment of which would do something to meet the grinding poverty of the people. The book is, as we have said, frankly Ayurvedist, and the author expresses a wish, in his preface, that the Ayurvedist system were more closely and sympathetically studied. An article on the indigenous systems was published in this *Journal* in 1923 (vol. ii, p. 477), and was written after an impartial study of the subject, based solely on material furnished by a number of distinguished Ayurvedists. The conclusion reached was that Ayurvedism represents a stage in the development of medical science that is centuries behind the present level of knowledge. This conclusion implies no disparagement, for Ayurvedism is admittedly a subject of very great historical interest. Western medicine has passed through a similar stage, and it must be obvious to Ayurvedists that their science cannot remain stationary if it is to survive. It would be unreasonable to suppose that their ideas can be transformed in a day; the change is bound to be gradual, but of its importance for the welfare of the people of India there can be no doubt. It is possible that the main obstacles to further advance are the idea that science rests on authority, rather than on observation and experiment, and a failure to recognize that the *ipse dixit* of an authority, however venerable, is almost certain to contain an admixture of error, and is not unlikely to be a mere legend or play of the imagination.

#### NOTES ON BOOKS.

In *Rebuilding the Child: A Study in Malnutrition*,<sup>†</sup> Dr. FRANK HOWARD RICHARDSON of Brooklyn, New York, the author of *Parenthood and the Newer Psychology* and of *Simplifying Motherhood*, addresses parents, teachers, nurses, and doctors, but the simple, somewhat elementary, style is perhaps better fitted for the parents. Malnutrition, according to the editorial foreword, which tells the reader that this book appeared as a series of articles in the *Trained Nurse and Hospital Review*, is the great disease of the American school child, and is shown by underweight for age and height, the latter being the more important; in fact, Dr. EMERSON, who contributes the introduction, neglects the age factor altogether. The child has a pasty face with a tired, don't-care expression, the chest is flattened, the angles of the scapulae stick out like rudimentary wings, and the abdomen sags and is prominent from want of tone. Malnutrition is not ascribed to deficiency of food, but to five classes of causes—faulty health habits,

\* *Pulmonary Tuberculosis*. By G. T. Henry, M.A., M.D., Oxon., M.R.C.P. Lond. London: E. Arnold. 1927. (Cr. 8vo, pp. 212; 5 figures. 7s. 6d. net.)

† *Études sur les affections de la colonne vertébrale*. Par André Léri. Paris: Masson et Cie. (6 x 8½, pp. vii + 526; 115 figures. 7s. 6d. net.)

\* *The Indian Materia Medica*. Edited and published by K. M. Nadkarni. Bombay: K. M. Nadkarni. 1927. (Cr. 8vo, pp. xxviii + 1142 + lxxxviii. 18s. net.)

† *Rebuilding the Child: A Study in Malnutrition*. By Frank Howard Richardson, M.D., F.A.C.P. With an introduction by W. R. P. Emerson, M.D. London and New York: G. P. Putnam's Sons, Ltd. 1927. (Cr. 8vo, pp. xxvi + 319; 44 figures. 7s. 6d. net.)

faulty food habits, family strain, school strain, and physical defects—which are discussed in separate chapters. The subheading of the chapter on faulty health habits is "Americanitis." Among the directions given to parents in connexion with faulty food habits much stress is laid on the elimination from the diet of "added sweets," on stopping cream, and reducing the quantity of butter to scanty proportions. The method of treatment advised is inculcated by the system of the nutrition class, which Dr. Richardson had conducted for some years.

*Problems in Psychopathology*,<sup>8</sup> by Dr. T. W. MITCHELL, is based upon a course of lectures delivered to an audience drawn from members of the British Institute of Philosophical Studies. Following a chapter on the earlier development of psychopathology, the remainder of the book is devoted to an exposition and discussion of the theories of Freud. The writer, who is evidently now an adherent of the psycho-analytical school, writes with the clarity which characterizes his other contributions to psychopathology—and it is assuredly not an easy task to make the more recent views of Freud in respect to the development of the ego and the nature of the instincts comprehensible to the uninitiated reader. In concluding his book Dr. Mitchell states that the fundamental conceptions of psycho-analysis are those of conflict and repression, the unconscious, infantile sexuality, and transference; and he then proceeds to show how the post-analytical schools of Rivers, Jung, and Adler have arisen, and in what respects their tenets differ from those propounded by Freud.

A fifth and enlarged edition of Dr. W. D. ROSE's book on *Physical Diagnosis*<sup>9</sup> has now been published. This has been completely revised both as regards text and illustrations. Important changes appear in the section on the heart, where the clinical aspect of early heart failure has been especially emphasized, and the section on endocarditis also has undergone a good deal of careful alteration. Recent advances in the various methods of diagnosis have been incorporated in the text.

The favourable reception accorded to the first edition of the work by Dr. LEROUX-ROBERT on high frequency in oto-rhino-laryngology<sup>10</sup> has justified the preparation of a new issue. This does not differ in essentials from the first edition, but the author has taken the opportunity of calling attention to improvements in the elaborate instrumentation necessary. The surgical aspect is well described; this has established itself more firmly in England than the medical, which has perhaps been neglected unduly. The author again insists on the necessity of exact measurements in dosage. A work of this kind is necessary to those who employ high frequency in a scientific manner. To those who are content to work by rule of thumb it will not appeal so strongly.

*Lectures on the Biologic Aspects of Colloid and Physiologic Chemistry*<sup>11</sup> is a volume of half a dozen lectures given by different authors at the Mayo Foundation and the Universities of Minnesota, Iowa, Washington (St. Louis), and the Des Moines Academy of Medicine from 1925 to 1926. Their general theme is indicated by the title. The lecturers have all made original contributions to knowledge in various departments of colloid chemistry or physics, and their remarks carry with them that freshness of tone and presentation which is almost inevitably lacking in a mere review of the work of others, however painstaking and thorough. Clearly, the appeal of the lectures to individual readers will depend to some extent on personal tastes and interests. Professor Chambers's remarkably clear discussion of the properties of boundary membranes cannot fail to interest the cytologist; Professor Barton's discussion of the ultramicroscope will appeal rather to the colloidal chemist and the bacteriologist. To the general reader, perhaps, the most instructive lectures are the first, by Professor Millikan, on "The principles underlying colloid chemistry," and Professor Bovic's discussion on "The biological effects of light."

The former occupant of the office of bursar and lecturer at King's College for Women, Household and Social Branch, Miss F. E. FINDLAY SHIRRAS, has written an excellent little book, *Aids to Catering*,<sup>12</sup> with special reference to institutions. Her

chief object is to show that a large and attractive range of food can be provided at the common table, and at no greater cost or trouble to the kitchen staff than the more monotonous stodginesses that are too often found in schools and institutions. There are chapters that will be of help to the buyer, and information is given about meat, side dishes, stock, preserves and pickles, bread, and pastry of various kinds. There follow a calendar of seasonable food for each month of the year, hints on how to serve up the meat and fish, and finally the bills of fare of meals actually provided at the college for one whole year, day by day. An uncommonly attractive dietary is presented, good in balance, without hint of crankiness; and if the serving of it proved to be as good as the thought expended on the arrangement, then the girls in that college must have been a well-fed and contented group. The book is a good example of catering mixed with brains.

The number of medical men whose hobby is fishing must be very large; it is an excellent antidote to the cares of practice. The humorous novelist WILLIAM CAINE was a fisherman too, and his widow has collected into a book, *Fish, Fishing and Fishermen*,<sup>13</sup> sundry articles of his which first appeared in the *Field*, *Punch*, and other periodicals. Mr. Caine was a dry-fly fisher for trout—he preferred to call them trouts—and he regarded other forms of fishing as fit only for the baser sort of men. Even "dapping" with the dry fly inspired him to an essay. As a fisherman he was justly indignant at the pollution of streams by the manufacturer, and the fish-killing propensities of the beet-sugar enthusiast would have aroused his wrath. In an article on had form in fishing there is a conio diatribe against the man in the smoking-room who ventures to doubt the impressive statements of "fact" made by fishermen. Such a man is described as being at heart a "gudgeon-killer," who exchanges glances of the basest significance with his companion, "a doctor who dubs for eels by night with a ball of worms and worsted."

<sup>13</sup> *Fish, Fishing and Fishermen*. By William Caine. London: P. Allan and Co., Ltd. 1927. (Demy 8vo, pp. xli + 253; 1 portrait. 10s. 6d. net.)

## PREPARATIONS AND APPLIANCES.

### A MOUTH GAG.

MR. NORMAN M. EADIE, Royal Hospital for Sick Children, Edinburgh, has designed a gag for tonsillectomy and other operations in the mouth which has given great satisfaction. It embodies the following advantages.

The teeth plates, with soft metal bearing surfaces, exert pressure on the molar teeth, which are not liable to injury, as is the case with the incisors.

The pressure being applied equally to both sides by means of easily adjustable tooth plates, the instrument is rigid and cannot rock from side to side; for edentulous patients this is a great advantage. The pressure being applied equally to both sides allows the tongue plate to remain accurately placed upon the tongue, which does not bulge out from beneath

it. The outer surfaces of the tooth plates act as effective cheek retractors. With the moulded tongue plate sufficient depression of the tongue is obtained without undue tension upon the faucial pillars.

An anaesthetic tube is provided; while the three sizes of tongue depressor give it an almost universal range.

The gag is made by Messrs. J. Gardner and Son, Edinburgh.

### AN ASEPTIC CLINICAL THERMOMETER.

We have received from Messrs. Coates and Cooper (41, Great Tower Street, London, E.C.3) a specimen of their "Simplex" aseptic clinical thermometer, manufactured in this country. The thermometer has a small screw-top holder which fits into a metal case. Into the lower end of the case is inserted a moulded glass container, which will hold enough antiseptic solution (such as 2 per cent. carboly) to bathe the lower end of the thermometer. There are slits in the outer case through which the presence of enough fluid in the container can be ascertained, and this is made easy if the solution is coloured. The whole appliance is no larger than a cigar, and has a clip for the waistcoat pocket. The thermometer can be unscrewed in a moment and withdrawn without removing the case from the pocket, and the antiseptic fluid can be replenished almost as readily. Leakage is prevented when the thermometer is in use by means of a rubber valve. A broken thermometer can be replaced by heating the composition in the screw-top holder. The price to the medical and nursing professions is 8s. 6d. complete.

<sup>8</sup> *Problems in Psychopathology*. By T. W. Mitchell, M.D. The International Library of Psychology, Philosophy, and Scientific Method. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1927. (Demy 8vo, pp. v + 150. 9s. net.)

<sup>9</sup> *Physical Diagnosis*. By W. D. Rose, M.D. Fifth edition, revised and enlarged. London: H. Kimpton. 1928. (6 x 9½, pp. 819; 310 figures, 3 plates. 42s. net.)

<sup>10</sup> *La Haute Fréquence en Oto-Rhino-Laryngologie*. Dr. Leroux-Robert. Deuxième édition, rev. et complétée. Paris: Masson et Co. 1927. (8 x 11, pp. 25 fr. sans majoration.)

<sup>12</sup> *Aids to Catering*. By F. E. Findlay Shirras. Introduction by Walter Rimmer, M.A. London: J. M. Dent and Sons, Ltd. 1927. (Cr. 8vo, pp. ix + 115. 5s. net.)

## THE NEW PSYCHIATRY.

MAUNDSELY LECTURE BY SIR JOHN MACPHERSON.

THE Maundseley Lecture, under the auspices of the Royal Medico-Psychological Association, was delivered at the British Medical Association House, Tavistock Square, on May 16th, by Sir John Macpherson, formerly Commissioner in Lunacy for Scotland and Professor of Psychiatry in the University of Sydney.

Sir John Macpherson defined psychiatry in its literal sense as the medical treatment of mental disorders, which necessarily implied scientific investigation of their nature and causes. The commencement of the twentieth century was marked by the advent of psychopathology, though its significance did not at first attract much attention. For many years previously the medical world had been interested in Charcot's studies of hysteria, but it was reserved for one of his pupils, Janet, to demonstrate that hysteria was a mental disorder and that its varied phenomena could be interpreted in psychological terms. Janet's contribution to psychiatry was the concept of dissociation. In some respects his definition of hysterical dissociation was not entirely satisfactory, because it implied a splitting up of consciousness and personality. It was highly improbable that there could be such a splitting up, for the cortical mechanism integrated as a single system. The vital process called consciousness was one thing; the outward expression of that process, which was called behaviour, was quite another. Behaviour might give the appearance of split consciousness because of changes in the integration of cortical processes; in the same way double personality depended upon different integrations within the cortical mechanism at different times.

Dissociation was a comparatively new term, though fifty years ago a similar condition was described by Hughlings Jackson, who taught that all morbid nervous phenomena were due to two factors—a negative factor consisting of loss of function at a higher level, and a positive factor consisting of over-function at a lower. The causes of dissociation resolved themselves into two co-operating groups, termed by the lecturer the *causa causans* group, including the whole familiar series of physical and physical agencies, and the *causa sine qua non* group, which in the present state of knowledge could only be referred to generally as the inherent instability of the cerebral mechanism.

*Freud and Orthodox Psychiatry.*

It was in connexion with the cause of dissociation that Freud joined issue, maintaining that functional dissociation was caused by conflict of opposing psychological forces, and that the resulting symptoms were due to attempts on the part of the organism to adapt itself to altered conditions. Superficially such a statement appeared incompatible with contemporary views, but Freud proceeded to erect upon it a system of psychology which in a remarkably short time had captured, if not the assent, at any rate the attention, of the civilized world.

The Freudian theory and method were more firmly established than some people appeared to believe, for they were unassailable by direct argument or dialectic attack. To say that the Freudian hypothesis was embarrassing to psychiatry was no more than the truth; to say that it was supplanting the other was to exaggerate. The present position might be more correctly described as an *imperium in imperio*. The field of psychiatry was infinitely wider than that covered by Freudian doctrines, and its relations with the medical and cognate sciences were too close to allow the possibility of the new psychology superseding it.

*The Foundations of Objective Psychology.*

After some discussion of the vital functions of the cortex the lecturer went on to consider the foundations of objective psychology. From Pavlov's recent researches it was learned that cortical inhibition (physiologically a state of rest) had a tendency to irradiate from its point of initiation, and by a process of induction to cause excitation in neighbouring areas, which excitation arrested the spread of inhibition. Thus the cortex might be visualized as a mosaic of inhibitory and excitatory areas within which the dynamic activities of irradiation and induction acted and reacted in endless variety. Certain changes in cortical equi-

brum resulted in sleep, in a kind of hypnosis, or in actual mental perturbation. That the depressed and exalted phases of the manic-depressive syndrome depended upon states of cortical inhibition and excitation had long been believed, but a more definite knowledge of the mechanism of these conditions was due to the researches of Pavlov. Once the cortical equilibrium was profoundly upset the effect did not pass away immediately, but might last for weeks and months, as was known from experience, and also again from the work of Pavlov on dogs.

There was no single symptom in the whole range of mental disorders which was not represented in the mental processes of normal people. We were dissociated from our surroundings when we were engaged in any absorbing occupation, when we forgot, and when we fell asleep. "When we dream, we are insane." As we were neither omniscient nor able to see into the future we were credulous, superstitious, and suspicious, and we developed many harmless delusions, the mechanism of which was the same as that of the delusions of the insane. We were only saved from insanity because our more or less efficient cortical mechanisms were able to correct our mental reflections and to inhibit our tendencies to abnormal behaviour.

*The Question of Certification.*

It was abnormal behaviour, the outward expression of cortical dissociation, that determined the necessity or otherwise of certification. The person who certified ought to be able to do so, not on the ground of abnormal behaviour alone, but also on the nature and cause of the cortical dissociation. Therefore medical education and experience were required for certification; the statutory appointment of a layman to revise the opinion of the medical certifier could be regarded only as a device to allay public suspicion. If proof was needed as to the prevalence of public suspicion it could be found in the provisions of the Lunacy Act, 1890, which showed less concern for the welfare of the insane than for the protection of the sane.

In any human system of the dimensions of lunacy administration it would be foolish to assert that mistakes and abuses could not occur; but the lecturer thought they must be extremely few in number. In his own experience he had never come across a single instance of abuse of certification or detention, but he had had cause to deplore the hardship imposed upon patients and their relatives by the reluctance of the medical man to certify. The same prejudices which influenced the framers of the Act of 1890 could be discerned in recent cases in the courts, not so much in the motives actuating the litigants as in the atmosphere of vindictiveness involving the proceedings. He had happened to be in a distant part of the Empire when newspaper reports of these cases were forthcoming; there they were received with amused surprise—amusement that courts of justice should deliberate for weeks over issues which appeared to present no great problems to the man in the street, and surprise that the Mother of Parliaments should not have devised less clamorous methods for the adjustment of disputes involving such pathetic and morbid details. He praised, by contrast, the simple and elastic administration of lunacy law in New South Wales, where it had recently been arranged that every large general hospital should make provision for the treatment of patients suffering from mental and nervous disorders. This was accomplished without legislative enactment.

The aims of the scientific spirit behind psychiatry, concluded Sir John Macpherson, could best be achieved by the admission of all cases of mental disorder to public hospitals without certification or judicial intervention. The great majority of patients and their relatives would welcome such an opportunity. There was sufficient legal machinery to deal with the small recalcitrant minority who would refuse to enter a hospital or remain in it. In addition to the existing mental hospitals advantage should be taken of every opportunity of utilizing the many scientific facilities of general hospitals by providing accommodation for the treatment of mental disorders in their vicinity. Such a provision, on an enlarged scale, was specially desirable in every centre of medical education. If mental patients had the opportunity of such informal access to treatment as was accorded to patients suffering from other diseases,

mental disorders would be robbed of some of the terror and opprobrium attaching to them; psychiatry also would be brought into closer relations with general medicine, whereby its scientific spirit would be widened and its therapeutic efficiency improved.

### CHRONIC ARTHRITIS.

THE publication of Dr. J. A. Glover's report<sup>1</sup> on chronic arthritis, with special reference to the provision of treatment, was mentioned in the *Journal* of May 12th, but in view of the recent conference on rheumatic diseases<sup>2</sup> at Bath, in which Dr. Glover took part, we now give a more detailed summary of this official document issued by the Ministry of Health.

This report, which is the third to deal with aspects of the problem of rheumatism, has been written in fulfilment of a promise given by the Minister of Health to a deputation from various approved societies, and the Chief Medical Officer, Sir George Newman, in a prefatory note, stresses the need for the organization of an adequate treatment in efficient centres if the very heavy claims on the funds of these societies are to be effectively reduced. Dr. Glover begins his report with a short section on the history of chronic arthritis, and then enters upon the difficulties of classification. The scheme used here is the same as in the previous report on the incidence of rheumatic diseases, and comprises rheumatoid arthritis (including infective polyarthritis), osteo-arthritis, gout, and a fourth group of "chronic joint changes unclassifiable." This scheme is amplified and discussed, and a table sets out the main points in differential diagnosis. The present report is mainly concerned with treatment, but a summary of some previous work on incidence is included, dealing particularly with insurance statistics, both British and foreign.

#### Etiology.

In the second section the more important problems in the etiology of chronic arthritis are discussed. Dr. Glover does not dogmatize on the question of heredity and diathesis, but quotes authorities supporting the various views. The prevalent idea is summed up in the statement that "the study of the family history of parents [<sup>2</sup> patients] will incline most people to the opinion that probably some hereditary influence does play a part in the production of chronic arthritis." The rather curious sex incidence of the various forms of the disease is next discussed, followed by some comments on the age of onset. There appear to be certain factors which play a part as predisposing causes in the production of chronic arthritis, and of these occupation, chill, dampness of houses or of localities, water supply, antecedent diseases, pregnancy, menopause, and mental stress are mentioned. The theory of focal sepsis is well reasoned. Here Dr. Glover observes: "We must regard chronic arthritis as an end-result, which may be caused by the results of the action of many different bacteria." After discussing the views of Timbrell Fisher, Hare, and other workers, he concludes that "the role of focal sepsis in the production of joint disease is not clearly known," but "the value of [the] theory of focal sepsis must, however, be interpreted chiefly in the light of clinical results." Disorders of metabolism are also held by authorities to play a part in a group of cases in which some inborn error or some acquired fault of metabolism is the primary cause. The results of various biochemical investigations in this field are summarized under the headings of basal metabolism, urinary analysis, and blood analysis, while the occurrence of achlorhydria and endocrine disturbances is also mentioned.

#### Treatment.

Coming to the main part of this report, Dr. Glover emphasizes from the start the importance of early diagnosis.

"When a patient presents himself or herself with any symptom or sign suggestive of chronic arthritis the practitioner has two clear and urgent duties, the first to attempt to differentiate the variety of arthritis present and the stage to which the disease has progressed, and the second, even more important, himself to begin that determined search for an infective focus, in which later he may probably have to invoke specialist aid."

The next steps consist of a specialized search for focal sepsis and the measures to be undertaken for removal. In an analysis of some 545 cases it was found that demonstrable foci were present in 70 per cent. In this large group dental sepsis was the predominating form, and the whole question of the teeth in chronic arthritic conditions is next dealt with in a thorough manner. The need for expert dentists and good dental radiograms is stressed and the dangers of wholesale extraction are not overlooked. On this point Dr. Glover wisely remarks:

"... whilst it has been necessary to sound a note of caution about wholesale or numerous extractions, it must be remembered that dentists are on the whole conservative, and that one tooth with hidden root sepsis left in the jaw may be quite sufficient to keep up a chronic arthritis."

Tonsillar sepsis, nasal sinusitis, and intestinal infections are next dealt with, and also urinary infection, especially in regard to the analogy of gonococcal arthritis. The septic focus having been dealt with, the question of vaccine therapy next receives attention under the headings of autogenous vaccines, stock vaccines, and non-specific protein therapy. The last, especially when carried out with T.A.B. vaccine, is urged by authorities for the early case, and certainly the results here set out appear to warrant its more frequent use. Dietetic measures, in some instances "feeding-up" and in others cutting down the diet, are described, and the theory of vitamin deficiencies is mentioned. Drug treatment is summed up in half a page, and the absence of any comment on this is itself of significance. Next comes a long section on physiotherapeutic measures in chronic arthritis, whereby heat and "other insults" may be applied to the skin and joints. The principles of hydrotherapy and balneotherapy are set out, and details of the chief methods employed are given with illustrations. The internal administration of mineral waters is very fairly dealt with, and despite the unproved doctrine of the specific action of mineral waters in the treatment of chronic arthritis, it is concluded "that spa treatment may and should play a very important part in the treatment of chronic arthritis." Surgical measures required in chronic arthritis are also discussed, and the difficulties of assessing the results of the treatment of chronic arthritis by any means are explained.

#### The Provision of Treatment.

It becomes obvious as the methods of treatment are set out that the provision of a team of workers is necessary from the outset, and that appropriate treatment, even if it can be obtained, is a matter of very considerable expense. The existing provision of treatment in the general hospitals, in the Poor Law infirmaries, and in the spa hospitals is discussed, and the urgent need for further facilities is manifest. The work already done by the general practitioner in the past receives appreciative notice, and for the future Dr. Glover writes:

"... the general practitioner will often have the opportunity of seeing such cases in the early stages when discovery and removal of the infecting focus and other appropriate treatment affords a greater chance than at the later stages of effecting a speedy and permanent cure. If the general practitioner is not content merely to relieve immediate symptoms; if he recognizes the necessity of searching for the cause, and if he exercises the tact, patience, and energy necessary to persuade the patient to submit to the necessary treatment, whether given by the practitioner himself or by others, invaluable time may be saved."

The need for physical treatment centres, as outlined in the annual report for 1925 of the Chief Medical Officer of the Ministry of Health, is insisted upon, and the possible provision of "arthritis units" to fulfil the purpose of research and observation as well as treatment is mentioned. Increased use of the existing spa hospitals for early cases is also urged. The out-patient clinics to be established, if funds permit, by the British Red Cross Society and the British Committee on Rheumatism are looked upon as the beginning of the provision of such clinics throughout the country, and the need for educating the public in preventive measures, especially with regard to dental sepsis, is emphasized.

In an appendix Dr. Fortesene Fox and Miss Margarethe Mautner describe the treatment of rheumatic diseases by physical methods in Germany.

## THE EARLY DIAGNOSIS OF CANCER OF THE RECTUM.

THE medical man whose patients can persuade him to give them offhand "something for piles" sounds the death knell of many an early case of cancer of the rectum; for it seems certain that, of all the types of cancer with which the surgeon has to deal, those occurring in the rectum and colon which are dealt with by excision at an early stage give better ultimate results than those arising in almost any other part of the body. The importance, therefore, of early diagnosis cannot be over-estimated or too often reiterated. The Subsection of Proctology of the Royal Society of Medicine recently held an interesting discussion on this subject (of which a report appeared in our last issue at page 846), and if there was one point above all others made most abundantly clear it was the imperative need for a routine digital examination in every case presenting rectal symptoms, no matter how trivial or unimportant they may appear to be. Everyone knows that this precaution is frequently neglected—the patient may resent it, the time or the surroundings may be inappropriate, the doctor may be hurried and overworked—and only too often the golden opportunity of recognizing a really early and curable case of cancer has slipped away. It is but too true that in far too many instances the patient does not consult a doctor at all until the growth has extended beyond all prospect of any curative treatment in our present state of knowledge, although it is satisfactory to learn that there is some evidence indicating not only that patients are coming to their doctors at an earlier stage of the disease, but that the medical profession as a whole is more alive to the necessity for earlier diagnosis and the value of early treatment.

Whereas the great majority of malignant growths of the rectum and recto-sigmoid are within reach of digital examination, and may therefore be classed as accessible or external cancers in the same sense as growths of the cervix uteri or buccal cavity, yet there is a proportion just beyond the reach of ordinary examination, and the detection of the growth calls for a little more care and skill. It is in just these cases that the proctoscope has proved of such great value; well named "an elongated finger with a human eye," it is so simple in use, so easy and cheap to maintain, and so convincing in its demonstration of those dangerous three or four inches of the lower bowel just beyond reach of the finger, that it is matter for surprise that it has not yet fully taken its place in the practitioner's armamentarium beside the otoscope, the laryngoscope, and the ophthalmoscope. It is certainly as easy to use as any of them, and there is further the comforting reflection that the differential diagnosis of diseases of the recto-sigmoid is simple, for all the published figures indicate that if any chronic ulceration is detected this is very much more likely to be cancer than anything else.

If a growth develops in a portion of the bowel beyond the reach of the finger or the simple proctoscope, its demonstration and its differential diagnosis present a more complicated problem, for the long

sigmoidoscope will be necessary, and its introduction may require an anaesthetic. Moreover, even when the growth has been thereby visualized it may still be necessary to establish its exact nature by microscopic examination, and its precise extent by means of the barium enema and x rays. The microscopy of small portions of growth, obtained by passing special punch forceps up the sigmoidoscope, has now been reduced to so fine an art that the pathologist skilled in this work can not only give a very confident opinion as to the innocence or malignancy of the piece of tissue removed, but can also in cancer cases form a full idea as to the relative degree of the malignancy to be expected. Dr. Dukes showed many specimens to the meeting which well demonstrated the help he had been able to afford to his surgical colleagues at St. Mark's.

But what of those regions of the bowel in which digital or ocular demonstration of the presence of a lesion is impossible? What of those extensive areas of the colon beyond the reach of the longest sigmoidoscope—the caecum, ascending and transverse colons, the splenic flexure, and the descending colon? Here one must to a large extent depend upon the careful weighing up of evidence less direct in character, and in doing so must not neglect the history to be obtained from the patient. As Sir William Wheeler emphasized in the paper with which he opened the discussion, the information to be obtained by careful cross-examination of the patient may be invaluable, and the evidence upon which he laid most stress was the history of a gradual change from normal bowel action to something abnormal. Persistence of such a symptom in spite of treatment should arouse suspicion and point to the need for further detailed investigation. Examination of the abdomen may give no help, for it is only in the later stages, when obstruction is established, that visible peristalsis, "ladder pattern" of the intestine, or a palpable tumour becomes manifest. Naked-eye examination of the faeces may also be quite negative, for it is only in extensive growths or those low down in the bowel that obvious blood or mucus is to be expected. Chemical examination of the faeces is, however, a different matter, for most authorities concur in the belief that occult blood, especially if found repeatedly, is very strong evidence indeed of at any rate some kind of ulcerative lesion of the gastric intestinal tract; on the other hand, its absence proves nothing.

What is the next step? The doctor is faced with a patient whose symptoms present nothing more striking than the recent onset of some slight trouble with the bowels of rather indeterminate character; occult blood has been detected in the stools, and physical examination is negative. Is he to wait and watch events, or is some further action necessary? Indubitably the latter; and equally without doubt it should consist in careful x-ray investigation by means of the barium enema, and not the barium meal. It seems necessary to be most emphatic about this, for the value of the opaque enema as compared with the opaque meal is not yet sufficiently appreciated by many of those who send patients to the radiologist. A barium meal administered to a patient with vague abdominal symptoms, and a report that "nothing abnormal is to be seen," may induce a wholly unwarranted feeling of security, for, as every radiologist knows, the passage of a meal may be hardly if at all delayed by a growth in the large bowel, which is revealed at once in a barium enema by its typical irregular filling defect, found constantly in all plates and at successive examinations. There are, of course, fallacies, both positive and negative: the positive

induced by faecal matter, spasm, or extrinsic tumours which mimic the appearance of carcinoma and must be guarded against by careful preparation of the patient and repetition of the photographs. The negative fallacies are largely dependent upon imperfect technique, insufficiency of the enema, or lack of appreciation of the fact that the ordinary photograph shows only one plane of structures like the colon and sigmoid, which have no fixed anatomy. It is obvious that a filling defect in a portion of bowel whose axis is parallel to the path of the x rays might show nothing abnormal on the plate. Dr. Graham Hodgson described how he had successfully overcome this particular difficulty by an ingenious method of taking oblique views.

The trend of the discussion on May 9th made it quite clear that the more general use of the proctoscope and the sigmoidoscope, together with the development of the barium enema, have put the diagnosis of cancer of the rectum and colon on a much more scientific basis. The combined work of the surgeon, radiologist, and pathologist has effected much, and will reach its fruition when the general public can be persuaded that not all rectal symptoms indicate "only piles."

### THE HARVEY TERCENTENARY.

THE celebrations of Harvey's publication three hundred years ago of the immortal *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus* have well illustrated the delectable doctrine that science knows no national or geographical boundaries. In March last the College of Physicians of Philadelphia, which rejoices in a wealth of Harveian treasures, paid its tribute, and was followed by Baltimore and Boston. Last week the Royal College of Physicians of London, as our columns have shown, organized a wonderfully successful celebration attended by delegates from twenty-one countries; and during the present week the Académie de Médecine of Paris, with that talent for graceful acknowledgement of pioneers in science which has in recent years been so much in evidence in generous recognition of British leaders such as Sydenham and Lister, has joined with her allies in commemorating the three hundredth birthday of Harvey's great achievement, which corresponds with the three hundred and fiftieth anniversary of his own birth. It may be recalled that the tercentenary of Harvey's birth was marked by a memorial fund to erect a statue at Folkestone, where he was born, and by a dinner in the College of Physicians' Library, when T. H. Huxley delivered a eulogy on Harvey's service to science and medicine.

The organization of this month's British commemoration was very appropriately in the hands of the Royal College of Physicians of London, whose chief glory is William Harvey, and it is specially fortunate that the President, Sir John Rose Bradford, whose early physiological work won him the Fellowship of the Royal Society, was able to correlate the activities of the College with those of the physiologists. Harvey's publication of his discovery of the circulation was even more important as inaugurating the modern method of experimental research, and the willing recognition by physiologists of this epoch-making event was a foregone conclusion. That the Fellows of the College are still obedient to the exhortation "to search and study out the secrets of Nature by way of experiment" was graphically shown by the convincing cinematograph films of Harvey's original physiological experiments as repeated by Sir Thomas Lewis and Dr. H. H. Dale, and exhibited to enthu-

siastic audiences at University College on May 15th and 16th. These demonstrations of the work which constituted "the new birth of physiology" were supplemented by other demonstrations bearing upon some more modern work on the circulation, both at University College, London, and at the meeting of the Physiological Society at Cambridge on May 19th with which a memorable week so fittingly concluded. It was a happy thought to include in the proceedings a luncheon party for the delegates at St. Bartholomew's Hospital (where Sir Wilmot Herringham gave a strikingly eloquent and comprehensive address on Harvey as a hospital physician), and visits to the two ancient English universities which also claimed Harvey at different periods of his active life. The success of the Harvey celebrations and the smoothness with which everything went were the result of much thought and attention to detail. The fact that this was a labour of love must not allow our debt to the Royal College of Physicians of London, its President, and Officers—and especially the Registrar, Dr. Raymond Crawford, fit representative of the scholar-physicians—to pass quietly into oblivion without an expression of gratitude.

The historical aspect of the three hundredth anniversary of Harvey's book has been admirably brought to the front by the publication of a facsimile of its first edition, presented to each of the delegates by the College of Physicians, and by the appearance of two further works—one old, a reproduction of the first English translation in 1653 of the *De Motu Cordis* (Nonesuch Press), and one new, *A Bibliography of the Writings of William Harvey, M.D.* (Cambridge University Press)—both due to the scholarly energy of a member of our profession, Mr. Geoffrey Keynes, the bibliographical authority on Sir Thomas Browne, Blake, and Donne.

### RESEARCH BY OBSERVATION.

"WHEN we are reduced to observation, science crawls," said Lord Moulton twenty years ago. "When and in proportion as you can use experiment, the science advances rapidly. . . ." In the early pages of this issue we publish an account of an inquiry by Mr. John Morley into abdominal pain as exemplified in acute appendicitis. Though the physiologists have taught us very much, yet for lack of adequate opportunity for experiment "pain" still escapes complete elucidation. Here, then, should be a legitimate field for research by observation, and we have to-day a restatement of a particular case which was set forth by Sir Henry Head in our columns some years ago.<sup>1</sup> "In the early stages," he said, "before perforation has taken place, widespread pains may be present in the abdomen, corresponding to the afferent supply of the upper parts of the digestive tract. Such pains are due to abnormal movements of the stomach and intestine, and express the reaction of normal parts to a lesion situated in some allied physiological system. But when the appendix becomes perforated and inflammation of the peritoneum ensues, these referred pains are replaced by local manifestations, accompanied by deep tenderness over inflamed parts." Mr. Morley would confine the source of the initial pain to tension in the muscular wall of the appendix itself, and in his arguments in favour of local peritonitis as the exclusive source of the later rigidity and local pain he omits one provided by Head, who noted that the absence of tenderness in the loin, both to superficial stimulation and to deep pressure, is proof that its origin is not segmental reference from the viscus. The second part of the thesis is an attempt, so far as the evidence from appen-

<sup>1</sup> *British Medical Journal*, 1922, vol. 1, p. 1.

dicitis goes, to disprove the existence of any viscerosensory or visceromotor reflexes. Localized tenderness and rigidity and localized pain, since in appendicitis another explanation is forthcoming, are not in his view the expression of such visceral reflexes. Mackenzie, he says, "did not appear to appreciate the exquisite sensitiveness of the parietal peritoneum to even slight degrees of inflammation," and accordingly failed to perceive the part played by a peritoneo-muscular reflex in protective muscular rigidity. But on turning up *Symptoms and their Interpretation* we find, a few pages later than the paragraph he quotes, this statement: "... appendicitis may give rise to symptoms which are entirely confined to the reflex group, until the inflammation extends to the abdominal wall, when another series of symptoms may arise which are produced by a different mechanism." Both Head and Mackenzie were alive, it seems, to the observations upon which Mr. Morley relies, but they were less prone to generalize, and readier to admit exceptions to the general rules established by clinical observations. Most surgeons, we think, will agree upon the great frequency of correspondence between their own similar observations and operative findings, but few perhaps will not have met disconcerting exceptions, even in appendicitis. Granting, however, that in general terms all Mr. Morley says is true, there are other observations to be considered. Is muscular rigidity, familiar as a clinical sign of gastric and duodenal ulceration, dependent on stimulation of the peritoneum? Surely not. Is there no muscular rigidity associated with tonic spasm of the ureteral muscle, though the peritoneum in contact with the ureter is not inflamed, and indeed belongs to what Cope calls the "non-demonstrative" area? What of the viscerosensory reflexes associated with cardiac disease, with bladder and prostatic lesions? What of the tenderness in the scalp related with visceral stimuli in the whole vagus field? If we call in aid, to support Mr. Morley, the deep tenderness over an area of pleuritic inflammation, there is still the difficulty that with the outpouring of fluid this deep tenderness disappears, and disappears, it may be, only up to the level of that fluid. A point of weight is scored by Mr. Morley in his insistence on the fact that muscular rigidity and hyperalgesia are purely right-sided, whereas, if visceral in origin, they should be bilateral, seeing that the intestine is developmentally median. It is curious, however, that laterality is, sometimes at least, recognizable in the case of ulcers of the stomach and duodenum; that we are able to differentiate colic in the ascending from that in the descending colon; that the areas of hyperalgesia of cardiac disorder show clear evidence of segmental distribution, with developmental sequence, and yet are often unilateral. It is a case, then, but not a conclusive case, that Mr. Morley presents against these reflexes. There will be a great measure of agreement with one deduction from these observations—namely, that hyperalgesia is not a trustworthy diagnostic sign; and there will be a considerable measure of sympathy with his expressed desire to simplify diagnosis for the student by the elimination of any reflexes that darken counsel.

#### THE INTERNATIONAL CONTROL OF DRUGS OF ADDICTION.

No great satisfaction can be derived from the discussions which took place during the sessions of the League of Nations Advisory Committee on the Traffic in Dangerous Drugs, held last month at Geneva. The Convention of 1925 remains unratified by a sufficient number of the requisite Powers to bring it into operation. The Control Board for which it provided, and upon which the Geneva conferences which drafted that Convention set so much store, has accordingly not been set up. Hence the machinery which the chairman of the second Geneva conference, M. Zahle, declared three years ago would initiate a

"movement which will accelerate from day to day and from month to month," still remains inoperative. The Hague Opium Convention of 1912, which the Geneva Convention of 1925 was to "greatly strengthen," is accordingly the only international instrument available for control of traffic in opium, cocaine, and similar habit-forming drugs.<sup>1</sup> Indeed, it was contended by the American delegates that the later Convention derogated from the spirit, if not the letter, of the earlier pact of 1912 in the matter of limiting the production of opium and in the suppression of opium smoking. The Advisory Committee is reported to have been staggered and appalled at the extent and the extension of the illicit traffic in the crude and the manufactured drugs. The chaotic state of the central government of China has been accompanied by the reversion of that country to the position of being one of the chief producers of opium. The Government of the Straits Settlements, it was alleged, was responsible for an increased consumption of smoking opium from 43,000 kilograms in 1925 to 55,000 kilograms in 1926, and the only justification vouchsafed appears to have been that if the Malay Government had not supplied the drug smugglers would not have failed to do so. Then, again, it was asserted that hundreds of kilograms of morphine were being exported from France, ostensibly to Germany. The German delegate, on the other hand, maintained that such imports had not been received, and it was suggested that the consignment had passed through Copenhagen to Russia for illicit use. The records of imports and manufactures of cocaine in Japan likewise attracted attention, and were said to amount to a total four times greater than the world average. The Japanese delegate somewhat irrelevantly replied that Europe had tried eighty years ago to convert Japan to opium smoking. As regards the world production of opium, this had been recently estimated at more than 8,000 tons per annum, whereas the most liberal estimate of the "legitimate" need is less than one-tenth of that amount. Another disquieting feature was the extensive manufacture of codeine. During the first Hague Conference on Opium in 1911-12 a good deal of discussion took place as to whether codeine, like heroin, should be included as a dangerous drug. The British delegates urged its inclusion; the German delegates opposed, and maintained that there was no evidence to show that codeine was a drug of addiction. One of the British delegates promptly cited a case of "codeinismus" from the columns of the *Klinische Wochenschrift*; but finally, to secure agreement, codeine was omitted from the Convention. Signor Cavazzoni, the Italian delegate, again reiterated his distrust of the "Board of Control," proposed by the Geneva Convention of 1925, as being too aloof from the organization of the League of Nations to be effective and trustworthy. He also again pressed for governmental supervision or ownership of all manufactories of dangerous drugs. An alternative proposal by the German delegate, Dr. Anselmino, was the creation of a great international drug syndicate or trust, with which the League of Nations should enter into organic relationship by way of representation. All these proposals, coupled with the admitted fact that the situation as regards the international control of dangerous drugs and the suppression of illicit traffic therein is getting worse rather than better, seem to point to the principle which has been consistently advocated in these columns, which has been supported persistently in America, and which is implied by British legislation—namely: (1) that the use of opium, cocaine, their products, and similar drugs for other than medicinal purposes is an abuse and not legitimate; and (2) that to prevent such abuse it is necessary to control production at the source, so that there will be no surplus for non-medicinal or illegitimate purposes.

<sup>1</sup> The agreement made between Powers having possessions in the Far East, signed at Geneva in February, 1925, and published in a White Paper (Cmd. 2035), relates exclusively to "prepared" or smoking opium.

## THE CASSEL HOSPITAL.

IN the report of the Cassel Hospital for Functional Nervous Disorders for the year 1927 the medical director, Dr. T. A. Ross, continues his policy of discussing only patients who have been at least twelve months away from the hospital. As an attempt is made, with considerable success, to keep in touch with former patients by getting them to report progress once a year, the results described are well tried, and have among hospital reports a peculiar value. This year's report, brief as it is, is full of interesting facts and suggestions. It furnishes, as in previous years, a striking justification of the methods of treatment employed at the hospital. In the group of patients for whom this institution is specially intended—the psychoneurotic group, of hysterics and anxiety states—the record is impressive, whether for percentage of improvement, consistency of results from year to year, or permanence, and this in spite of the fact that the claims of recovery or improvement are made with great caution, and the results are tested at length by the only criterion that is of nearly unassailable value—the test of the return to everyday life. In the present instance, of 102 psychoneurotic patients treated in 1926, 91 have so far replied to an inquiry about their health, and of those 70 reported themselves as well or much improved. This represents 77 per cent. of those replying, and contrasts with a percentage of 75 in 1925, 74 in 1924, 77 in 1923, and 68 in 1922, which was the first year to be so reported. These are remarkably consistent and well-sustained results, and in evaluating them it should be remembered that they have been brought up to date, and so give evidence of durability. They would be still more impressive if some indication were given of the duration of the illness before treatment was instituted. It has to be borne in mind that in some respects the Cassel Hospital population is a selected one—selected chiefly for its difficulty—for it is composed largely of patients who have been ailing for years, many of them for the greater part of their lives, and who have had many treatments with fleeting success. This may very well account for the pessimism of the report in regard to a small group—the obsessional group—of which there have been only twelve in the hospital since it opened. Experience in private and out-patient practice gives a more favourable impression of this type of illness, especially when it occurs in children and adolescents, than Dr. Ross has received from the Cassel Hospital material, which is mainly adult. From the figures quoted the therapeutic results in the chronic psychoneuroses, which are usually regarded so pessimistically, contrast very favourably with the results of treatment of other forms of chronic disability. In this connexion we note with interest that it is found to be a useful policy to have some former patients back for a brief second period of residence. Of 24 patients who returned under these conditions, 17 are now much better or well, so that the experiment seems fully justified. Such patients return usually to discuss the effect of putting into practice in ordinary life what they had learned in the Cassel Hospital, and to adjust any points in which they have failed to apply it satisfactorily. The idea of diagnosing dementia praecox in the early cases sent there has been abandoned; this is in accord with the most modern psychiatric teaching. It is not only unkind, but unscientific, to label patients "dementia praecox" merely because they present certain symptoms; the designation should be reserved for certain states of terminal dementia. For all earlier cases of this type the term "schizophrenic" is wisely preferred at the Cassel Hospital. It is of considerable interest that of the eight schizophrenics mentioned four are now well, and that most of them (Dr. Ross states) had to be discharged before recovery because they did not fit socially with the rest of the population, which is, of course, mainly psychoneurotic. He deplores the fact that it was impossible to provide special nurses to enable them to

prolong their stay sufficiently. Such patients undoubtedly feel themselves to be different from the psychoneurotic population, and the latter also are quick to recognize the difference. It would add still more to what is to be learnt from these very informative and constructive reports if more statistics could be given, such as the duration of illness, the number of hours of treatment, the length of the hospital residence, and the age of the patients. Some indication of the relative permanence of the results with each type of psychotherapy selected would further enhance their value.

THE LIFE-HISTORY OF EPIDEMIC ENCEPHALITIS  
IN THE CHILD.

FINDING that the prognosis in epidemic encephalitis in children has been insufficiently studied, Dr. Mary M. Stevenson records in the April issue of the *Archives of Disease in Childhood*<sup>1</sup> the results of her investigation of eighty-three cases, observed at intervals from 1918 to 1927. Twelve children had died, eight cases could not be traced, and sixty-three had been re-examined recently by the author. It was noted that 70 per cent. were boys, and the onset had occurred at ages varying from birth to 13 years. The disease began in most cases suddenly; after the acute illness there was a period of quiescence, followed later by the appearance of new symptoms. Mental alteration, nocturnal excitement, conduct changes, respiratory disturbances, the Parkinsonian syndrome, loss of accommodation, choreiform restlessness, myoclonic movements, and obesity occurred in that order of frequency. Fever was present at the commencement in most cases, and lethargy was a pronounced symptom in the majority. Of the motor disturbances described the most important were convulsions seen in the acute stage; choreiform restlessness, occurring both early and late; myoclonus, which appeared in both early and late stages and had persisted for years; and the Parkinsonian syndrome, occurring in the late stages only. The prognosis of Parkinsonism is extremely bad, the majority of cases being steadily progressive. The ocular symptoms included diplopia, strabismus, ptosis, nystagmus, loss of the reflex on accommodation, inequality of the pupils, and disc changes. Among the paralyses that of the seventh cranial nerve was the most frequent, and in six cases there were transient paralyses of the limbs. The reflexes varied, and in twenty-three cases pain of a severe neuralgic character was present during the early stages of the disease. Examination of the cerebro-spinal fluid showed it to be under slightly increased pressure, but clear. During the acute stage there was an increase of the cells for two or three months. The colloidal gold test of Lange was usually positive during the acute stage, although in the first week it was occasionally negative. During the chronic stage it was again negative. Nocturnal excitement with inversion of the sleep rhythm assumed a very prominent position in the sequels seen in this series; it lasted from one month to five years, the average duration being eighteen months. Derangements of respiration took the form of (1) attacks of rapid and noisy breathing, (2) continuous rapid breathing with occasional attacks of noisy respiration, and (3) apnoea. Respiratory ties, such as frequent clearing of the throat, nose-blowing, and sniffing, were also present. The onset of these respiratory troubles usually occurred between three months and three years after the start of the disease, and was a late manifestation. There is a tendency for these disturbances to disappear. Mental alteration was found in the majority of the cases, and tended to increase, in contrast with Shrubbs's findings. Changes in conduct were seen in forty-six patients; in most cases improvement has occurred.

<sup>1</sup> Vol. 3, No. 14. Issued by the British Medical Association. London: B.M.A. House, Tavistock Square, W.C.1. Yearly subscription (6 numbers), 25s. Single number, 4s. 6d.

Regarding the prognosis as to life, out of the author's series four children died during the acute stage and eight at varying periods after the acute illness. Only three of the whole series are normal; many are seriously crippled and need institutional treatment, thus demonstrating the seriousness of the outlook in epidemic encephalitis.

#### ARTIFICIAL PRODUCTION OF A FOWL TUMOUR.

Ever since Gyo and Barnard put forward their theory of the cancer "virus," a great deal of attention has been directed to the study of the Rous sarcoma of fowls, on which their argument wholly depended, and especially to the nature of the filterable extract of these tumours. Gyo claimed to have demonstrated that the extract contained two factors—the "virus" and the "accessory chemical factor"—neither of which was efficacious without the other; but the weight of scientific opinion has been unfavourable to this claim. It has even been doubted if the active principle of the fowl-tumour extract is of the nature of a virus, and Carrel has asserted that he has been able to produce tumours indistinguishable from the Rous sarcoma by injecting into fowls the pulp of chick embryos mixed with very weak solutions of arsenious acid or of indol. Carrel's claims in turn have been disputed by others, but Brebner<sup>1</sup> states that he has successfully repeated these experiments. But he has gone further. Impressed by the discovery of Warburg that tumours, placenta, and embryonic tissues have, in contradistinction to most other tissues, a greater glycolytic than respiratory property, he was impelled to try if the combination of placental extract and chick embryo pulp would have a similar effect to the Rous sarcoma extract. To this end he removed two placentae from a rabbit at or about full term, minced them finely, and mixed with them 10 c.cm. of saline. The mixture, after standing for thirty minutes, was centrifugalized, and the supernatant fluid added to the minced pulp of three eight-day-old chick embryos. This emulsion was injected into the pectoral muscles of two fowls. One of these fowls had developed a nodule by the twentieth day, and by the end of the forty-sixth day, when the bird died, it had a large nodule on the left side and a smaller one on the right. On dissection it was found that the tumours—grey-white in colour, firm in consistency, not very vascular—were actively invading the muscle substances. They showed no trace of embryonic tissue, such as cartilage, bone, or epithelial structures, as one would expect to obtain from the growth of the material injected. There were numerous metastases, especially in the lungs. The microscopic appearances were those of a sarcoma in which large cells predominated, with abundant cytoplasm and somewhat pale-staining reticulated nuclei—cells which were probably of mesoblastic origin—but the picture was by no means uniform, for dense cellular areas existed side by side with myxomatous areas, and there were a few giant cells and lymphocytes to be found. The metastatic deposits showed the same characters. The tumour was successfully transplanted into other fowls of the same breed, and had reached its fourth generation when the paper was written. The tumours were always progressive, had the histological characters of the original, gave rise to metastases, and proved fatal to the fowls in thirty-five days. Brebner further states that he repeated the experiments, using extract of guinea-pigs' instead of rabbits' placenta, and has produced similar tumours in six cases. So far he has not succeeded in propagating these tumours by filtrates or by desiccated material as in the case of the Rous sarcoma, but otherwise these fowl tumours are of a similar nature. No doubt this new observation will be thoroughly investigated by others; if it comes successfully through the test it will throw some light on the nature of the agent causing

these peculiar chicken tumours, and, incidentally, it will remove the foundation on which Gyo's theory was constructed.

#### B.C.G. AND NON-TUBERCULOUS INFANTS.

At a recent session of the Academy of Medicine in Paris Professor J. Lignières, while speaking in high terms of Dr. Calmette's B.C.G., deprecated its use for pre-immunizing infants who were not exposed to infective surroundings. Although he was convinced that B.C.G. was a powerful help in the struggle against tuberculosis, and ought always to be employed when contagion was to be feared, he thought that the introduction of a living organism into the tissues led to an infection which, though never producing the lesions of tuberculosis, might still be harmful. He pointed out that there was a large mortality in rabbits used for experiments with B.C.G.; that no trustworthy statistics were yet available on the vaccination of infants who were not exposed to tuberculous infection; and that, in any case, pre-immunization led to a prolonged infection of the lymphatic system by the B.C.G. Dr. Calmette reserved his reply to Professor Lignières until the session of the Academy on May 8th. Apparently he failed to recognize that Professor Lignières did not allege that the B.C.G. might produce tuberculous lesions in the vaccinated, and his answer was based mainly on this misunderstanding. He asserted, however, that experiments had shown that the mortality in rabbits was not due to injections of B.C.G., and he made the remarkable statement that in vaccinated infants the mortality from all causes was less than in the non-vaccinated. Professor Lignières again declared his admiration for the great discovery of Drs. Calmette and Guérin; he continued, however, to uphold his view that the use of B.C.G. should be avoided with healthy subjects brought up in non-tuberculous surroundings.

Dr. W. M. WILLOUGHBY, who has been medical officer of health for the Port of London during the past twelve years, was elected on May 17th by the Corporation of London to the post of medical officer of health for the City, in succession to Dr. W. J. Howarth, who retired recently owing to ill health.

THE first award of the Dalby Memorial Prize, for the best original work in otology during the previous five years, has been made to Dr. Otto Mayor of Vienna. The award is in the hands of the Council of the Royal Society of Medicine, acting on the recommendation of the president and vice-presidents of the Section of Otology.

THE annual general meeting of the Research Defence Society will be held at 11, Chandos Street, Cavendish Square, W.1, at 3 p.m. on Tuesday, June 19th. The Stephen Paget Memorial Lecture will be delivered by Sir Bernard Spilsbury, his subject being the work and responsibilities of a pathologist.

PROFESSOR HIDEYO NOGUCHI, of the Rockefeller Institute for Medical Research, died at Accra, on May 21st, from yellow fever. Professor Noguchi went to Accra last November to investigate this disease, and contracted the infection in the course of laboratory work.

SIR STCLAIR THOMSON has been elected a corresponding member of the Société de Laryngologie des Hôpitaux de Paris, of the American Stomatological Association, and of the Philadelphia Laryngological Society.

# The Harvey Tercentenary.

## BANQUET AT LONDON GUILDHALL.

THE Harveian celebrations in London concluded with a banquet given by the Royal College of Physicians at the Guildhall on Wednesday evening, May 16th. The reception by the President of the College, Sir John Rose Bradford, took place in the art gallery, and the company of nearly 500 Fellows and guests proceeded to tables in the great hall.

The President had beside him the German Ambassador and on his left the French Ambassador; other members of the Diplomatic Corps present were the Italian and Belgian Ambassadors, and the Austrian, Greek, and Finnish Ministers. The Government was represented by the Minister of Health and the Under Secretary for Scotland; the religious life of the nation by the Archbishop of York, the Archbishop of Wales, the Dean of Westminster, the Dean of St. Paul's, Cardinal Bourne, and the Chief Rabbi; law by the Lord Chancellor (Lord Hailsham), Viscount Sumner, Lord Wrenbury, Lord Blanesborough, Mr. Justice Rowlatt, Mr. Justice Maugham, Sir Ernest Wild, and Sir Thomas R. Hughes; industry and industrial science by Sir Alfred Mond, Sir Robert Hadfield, and Sir Charles Parsons; and the arts by Sir Frank Dicksee, Sir Reginald Bloomfield, and Sir Johnston Forbes-Robertson. The University of London was represented by Sir William Beveridge (the Vice-Chancellor) and Sir Gregory Foster; Edinburgh, by Sir Edward Sharpey-Schafer; Oxford, by Sir Farquhar Buzzard; and Cambridge, by Sir Humphry Rolleston. The three new Honorary Fellows who were able to be present (Sir Ernest Rutherford, Professor Pavlov, and Professor Wenckebach) were grouped near the President. Others on the principal table were Viscount Knutsford, Lord Somerleyton, the Earl of Crawford and Balcarres, Viscount Chelmsford, Lord Stanmore, Lord Riddell, and the High Commissioner for New Zealand. The great majority of the others present were medical men, including Lord Dawson of Penn; Sir Berkeley Moynihan, President of the Royal College of Surgeons of England; Sir James Berry, President of the Royal Society of Medicine; Mr. H. W. Carson, President of the Medical Society of London; Sir Robert Philip, President, Sir Ewen Maclean, President-Elect, and Dr. C. O. Hawthorne, Chairman of the Representative Body of the British Medical Association; Sir George Newman, Chief Medical Officer of the Ministry of Health; Sir Thomas Barlow, Sir Francis Champneys, Sir Anthony Bowlby, Sir John Bland-Sutton, Sir Wilmot Herringham, Sir James Fowler, Sir William Hale-White, Sir Thomas Horder, Sir Maurice Craig, Sir James Purves-Stewart, Sir Robert Armstrong-Jones, Sir William Wilcox, Sir Holburt Waring, Dr. Graham Little, M.P., and Dr. F. E. Fremantle, M.P.

### "The Memory of William Harvey."

After the loyal toasts had been honoured, the PRESIDENT, in few words, called upon those present to drink to "The Memory of William Harvey," and the toast was honoured in silence.

### "The Delegates."

THE MINISTER OF HEALTH, proposing the toast of "The Delegates," said that all would agree as to the greatness of the occasion which brought together so distinguished a body of men, including representatives from the universities and the learned societies of this country, of the British Dominions beyond the seas, and of numerous foreign nations. Many bore names which were held in honour throughout the whole of the scientific world. He noticed with particular pleasure the presence of Professor Castiglioni, representative of that University of Padua in which Harvey took his medical degree in 1602. Surely there could be no greater tribute to the influence of that wonderful treatise by Harvey than the fact that 300 years after its publication men of science should come together from all parts of the world to do him honour and acknowledge the debt they owed to him. Harvey's work was more than a discovery, it was a demonstration. So clearly did he state his problems, so skillfully did he marshal the evidence against the theories then current, so aptly did he illustrate by the results of his experiments the new theory which he put forward, that at one single blow he carried conviction to all his readers. Like another great scientist, Charles Darwin, he changed the whole current of men's thoughts. The present company had during the last two days listened to many appreciations of the work of Harvey from different aspects. The speaker was present that evening as the Minister for the time being responsible for the Department of Public Health, whose duty it was to prevent and avoid disease. Looking at Harvey's work from that point of view,

it seemed to him that the whole system of preventive medicine was based and founded upon his discovery. For what was preventive medicine? Was it not the science and art of providing for the population the food, warmth, exercise, and recreation that were necessary to maintain a normal healthy circulation, and on the other hand to remove and avoid those factors which favoured the onset of disease and impaired the resisting power of the body, which was itself dependent upon the same circulation? Harvey's pre-eminent place in medicine was given to him because he was the founder of modern physiology, and all the services which were carried on in the name of public health in this country, through the local authorities, medical officers, sanitary inspectors, health visitors, maternity and child welfare centres, clinics and hospitals, the health insurance system, even the housing programmes, were just various methods of securing and safeguarding the physiological balance of the life of man. Mr. Chamberlain concluded by saying that of the various factors which were working to-day for the peace of the world there was none which was more potent than the brotherhood of the healing art. Diseases knew no frontiers, took no account of nationalities, and those who were fighting in this great warfare knew full well that if they were to win the battle they had to pool their resources and to regard medical men and sanitarians of all nationalities as their comrades in arms. It was in this spirit that he welcomed the delegates.

Professor A. CASTIGLIONI said that the period during which, as a young man, Harvey listened with so much earnestness to the teaching of the greatest anatomist of the time, Fabrizio d'Aquapendente, was the greatest and most glorious in the history of the University. Galileo Galilei had laid the foundations of experimental science with his immortal words. Through the intelligence and foresight of the Venetian Republic the entire University, enjoying complete freedom in matters of education, was influenced by the spirit of this earliest and greatest of experimental philosophers. At the same university Andreas Vesalius, student and afterwards Professor, had established modern anatomy, and for more than forty years Padua was the centre of anatomical research in Europe. It was into this environment that William Harvey brought his high intelligence and profound powers of observation, and here he came to know of the discoveries of Realdo Colombo and Andrea Cesalpino. Italy could with pride testify that while England had the glory of being the country of William Harvey's birth, it was the ancient University of Padua which afforded this famous man his course of instruction in physiological thinking which prepared him for his great discoveries. The glorious Italy of the Renaissance, which in letters and arts carried high the torch of beauty and truth to illuminate mankind, remembered to-day with pride the work of William Harvey as that of a beloved pupil. The speaker said that he was giving voice also to the feeling of all Italians who were tied to England in a bond of long-standing friendship. They did not forget the opportune assistance rendered to their land at all times by a country which they loved and admired. In commemorating the work of William Harvey of immortal fame he took the opportunity to emphasize those ties of friendship and unity of purpose, and to recall all those brilliant men, at one time students at Padua, who had held prominent positions in the Royal College of Physicians of London. He also brought greetings and good wishes from this ancient school, which followed with pride and affection the successes of its sons in another land, and in the name of the University of Padua, and also in the name of all those Italians who followed with such interest the progress and glory of British science, he greeted the President and members of the Royal College with the words "*Vivat, crescat, floreat!*"

Professor W. H. WELCH of Johns Hopkins University also responded to the toast, saying that it was difficult for him to follow the eloquent address of Professor Castiglioni, who represented something very significant in the life of Harvey. He himself could put forward no such claim, but he did desire to express what he felt to be the good fortune of the delegates and guests in being allowed to participate in that commemora-

tion. There was something stirring in the thought that they assembled at the invitation and under the auspices of the Royal College of Physicians to celebrate an event unexampled in the history of human thought. The celebration had been in every way worthy of the event which it celebrated. The delegates had been received by the King, they had participated in some highly impressive and interesting ceremonies, they had visited not only the Royal College of Physicians, but Harvey's old hospital, St. Bartholomew's, and on the following days they were going to Cambridge and to Oxford. But he thought he was voicing probably the sentiments of very many of the delegates when he said that on the previous day, during the demonstrations at University College, they had felt themselves most vividly in the presence of the living Harvey. It was one thing to read about the fact that Harvey made this direct appeal to nature, that he really introduced independent scientific inquiry into the biological sciences, that he stood for biology in the same position as Galileo stood for the physical sciences, but to have this brought before the eye by demonstration was a singularly impressive experience. He thought that the prolonged applause with which the delegates endorsed the tribute paid by the President to Sir Thomas Lewis and Dr. Dale was more than ordinarily significant; they felt that they were applauding really the *persona propria*, as if Harvey had been before them and had conducted the demonstration. The delegates had also enjoyed the delightfully plain and simple and yet eloquent talk at Harvey's hospital by Sir Wilmot Herringham about Harvey the man. They realized what a man he was, a gentleman in every sense of the word, one who did not love to overthrow the spell of ancient authority, who did his work in a somewhat reluctant, slightly regretful way, one who was not altogether free himself from the trammels of mediæval thought, one who was not engaged in vituperation and did not light-heartedly abandon the old authorities. The speaker desired only to add how grateful he and his fellow delegates were to the Royal College of Physicians for having provided in so adequate a way this presentation of Harvey the investigator and Harvey the man. This visit would be one of the great experiences of their lives and an inspiration to them in future work.

#### "The Honorary Fellows."

The PRESIDENT next proposed the health of the newly installed Honorary Fellows, and repeated in substance the statement he had made at the reception at the College two days previously, which was reported in the *Journal* last week (page 867), explaining that the College had never had a roll of Honorary Fellows, though in history there were one or two who might by a stretch of language have been said to bear that title. Four most appropriate names had now been chosen for this honour: the Earl of Balfour, who in many directions had given great encouragement to medicine, Sir Ernest Rutherford, the distinguished physicist, Professor Pavlov, the doyen of physiology, and Professor Wenckebach, a man distinguished for the kind of work peculiarly associated with the genius of Harvey.

Professor WENCKEBACH addressed a few remarks in reply, modestly disclaiming any ability to speak for his great colleague Pavlov, but saying that Professor Pavlov's presence at that gathering was sufficient without any words. For his own part Professor Wenckebach felt himself singled out merely as one of a great army of practitioners in whose ranks he had served, and that the honour done him was really intended for them all. He was one of the hundreds of thousands of physicians who stood indebted to William Harvey, and not to William Harvey alone, but to the profession of medicine in Britain past and present.

Sir ERNEST RUTHERFORD also acknowledged the toast in graceful terms, saying that it was an idiosyncrasy of human nature that it appreciated most those marks of distinction which were least deserved. He felt, however, that his admission to the Fellowship of the College was attended by certain drawbacks, one being that he could no longer express his opinion of the merits of the medical profession with the same candour as heretofore. Harvey, he went on, was the first man to apply physics to medicine. It was true, as others had said, that all the essential facts on which Harvey based his great discovery were known before him. It was known that the blood flowed outwards in one direction, and inwards in another; but what he did, like Newton and others of whom the same was true, was to make a great generalization. All honour to the man who had the vision to do that! Harvey visualized the application of dynamics to the circulatory system. Sir Ernest Rutherford ended by asking his hearers what new scientific achievement they would most desire to see in their lifetime. A further generation would have made varied replies, but now,

with so many conquests made—flight, and wireless, accomplished, and television on the way—what remained but the achievement of the health of the community, and who could doubt that the disciples of Harvey would gain this also?

## Royal College of Physicians of London

Fellow 1607-1657  
Censor 1613-1625-1629  
Treasurer 1628-1629  
Lumleian Lecturer 1615-1636.

## Banquet at the Guildhall Wednesday 16th May 1928

#### "The Royal College of Physicians."

The ARCHBISHOP OF YORK, in proposing the last toast, that of "The Royal College of Physicians," declared himself on that occasion to be a layman of laymen, who had had probably less to do with doctors professionally than anybody else in that hall. Yet, after all, he might on that occasion represent the highest and most altruistic ideal to which the medical profession could possibly rise—that of a humanity so healthy that the occupation of the Royal College of Physicians would have gone. He had one link with the Royal College which he greatly valued. The principal founder and first President of the College, Thomas Linacre, became 440 years ago what he was happy to say he (the speaker) still was, a Fellow of All Souls' College, Oxford, and he hoped he might without presumption be regarded

as standing in the relation of founder's kin. That first President was indeed the precursor of the great man whose name was in all their hearts. It was but one hundred years before William Harvey began the experimental method of which he was the greatest illustrator, and Linacre as well as Harvey had the honour of graduating in medicine in the University of Padua, which had been represented with so much eloquence that evening. Linacre represented the union of medical science with letters and scholarship. He was the friend of Erasmus, Colet, and Thomas More. It was to be hoped that the connexion between the physician and scholarship and letters might be maintained. The study of humanities did give a unique distinction; he trusted that that old association between medicine and letters, that old succession of medical humanists who had done so much to give distinction to English life, would not be broken. Linacre also reminded him of the union between medical science and the Church, for he was during the last fifteen years of his life a clerk in holy orders. Then, as now and always, Theology was the queen of the sciences, and, like other queens, was apt to be somewhat jealous and dictatorial; for a considerable time she held Medicine under a somewhat painful constraint. But those days were passed; Medicine was now free, though he hoped that as there had been no divorce there would not even be any separation between the Church and Medicine, but a new comradeship based on freedom. They ought to be working together as fellow students in the spirit of science, with minds furnished as

became disciples of truth, and he could wish that the Royal College of Physicians would take the lead in a new scientific and independent inquiry on the subject of spiritual healing. He did not think there was any profession in the world where the connexion between science and humanity was more close than in the great profession of which the College was the head. There research, teaching, and practice were all fused together in one common enthusiasm, and he liked to think that at that very moment there might be, under the College auspices, some man, having the spirit of Harvey, on the very brink of some great new discovery. No sooner would any such discovery be made than it would be taken up by the great body of practitioners and applied in every cottage throughout the length and breadth of the land.

The PRESIDENT contented himself with but a few words in reply. He thought that those who had witnessed the demonstrations arranged at the College during that commemorative week would agree that this ancient foundation was not proving unworthy of the trust which evidently Harvey in his time reposed in her; the Fellowship of the College included many men on whom the mantle of Harvey obviously had descended.

[Our illustration is reproduced from the cover of the dinner programme, designed and executed by Mr. Emery Walker. This bust of Harvey overlooks the main staircase of the College.]

#### DELEGATES' VISIT TO OXFORD.

A large number of the delegates visited the University of Oxford on Thursday, May 17th, and were entertained at luncheon in Harvey's college by the Warden and Fellows of Merton. The party reached Oxford by train and were met at the station by the Regius Professor of Medicine (Sir Farquhar Buzzard), the Dean of the Faculty (Dr. Ainley Walker), and a number of other members of the University. They were conducted in cars to different centres, and the morning was spent in visiting the Bodleian Library, the Old Ashmolean Museum, the Lewis Evans collection, Magdalen College (hall, chapel, cloisters, and gardens), and Christ Church (hall, library, kitchens, and quadrangles). At the Old Ashmolean Museum Mr. R. T. Gunther, curator of the Lewis Evans collection, spoke of Harvey's work with Bathurst at Trinity College, where they studied the development of chicks in incubated eggs. At 1.15 p.m. the different parties re-united at Merton College, where they were met by the Professors in the Faculty of Medicine, and were received by the Warden and Fellows of the College. Luncheon was served in the College Hall to about one hundred guests. On a small table in the centre of the Hall were displayed some of the College books relating to the period of Harvey's wardenship, and a bursarial account showing his signature was exhibited. After the loyal toast had been honoured the Warden (Mr. Thomas Bowman) expressed in felicitous terms the pleasure felt by the College in welcoming and entertaining the delegates. Sir John Rose Bradford (President of the Royal College of Physicians) replied on behalf of the guests, emphasizing the important part played by Oxford and Oxford men in the early history of scientific and medical investigation in England. Subsequently the visitors had the opportunity of seeing the College library and gardens, and proceeded in small parties to spend the afternoon in seeing some of the other colleges and University institutions. A short account of Harvey's connexion with Merton, drawn up by Professor H. W. Garrod, Fellow of the College, was presented to each of the guests at luncheon. This recalled that Harvey went to Oxford with the King after the battle of Edgehill, and was incorporated M.D. in the University on December 7th, 1642. He was appointed Warden of Merton on April 7th, 1645, but in the following June, when Oxford surrendered to Fairfax, Harvey ceased to be Warden. Merton possesses very few records of Harvey's wardenship beyond two autographs, but the College Register contains a fairly full account of his appointment as Warden and of the circumstances leading to it, together with a copy of the letter of appointment. Four days after his appointment Harvey called the Fellows together in the Hall and delivered a speech, exhorting them to friendship and good-

will. He is believed to have spent most of his time at Oxford studying the incubation of fowls.

On Saturday, May 19th, by the invitation of Bodley's Librarian, the members of the Oxford Bibliographical Society viewed a collection of books exhibited to commemorate the tercentenary, at the Radcliffe (Science) Library, University Museum; and were addressed by Sir Farquhar Buzzard on Harvey's discovery of the circulation of the blood.

#### DELEGATES' VISIT TO CAMBRIDGE.

The last event of the week was a visit of the delegates to Cambridge on Friday, May 18th, where they were entertained at luncheon by the Master and Fellows in the Hall of Gonville and Caius College, of which Harvey was a member, graduating B.A. in 1597. The guests were received by the Master, Sir Hugh Anderson, M.D., F.R.S., who welcomed them in the name of the College, and recalled that its second founder, John Caius, was President of the Royal College of Physicians of London in 1555-61, 1562-64, and again in 1571-72. The thanks of the delegates and other visitors were conveyed to the Master and Fellows by John Cains's successor in the presidency, Sir John Rose Bradford. Some of those who travelled to Cambridge by motor car turned off by way of Saffron Walden to Hempstead, Essex, in order to visit Harvey's sarcophagus and memorial in the parish church, of which an account appeared in our issue of May 12th (p. 816), from the pen of the late Sir Dawson Williams. On the Saturday the Physiological Society met in Cambridge and held a luncheon party in the Hall of Downing College, in commemoration of the Harvey Tercentenary. Many of the delegates attended, and afterwards took part in the scientific proceedings held in the large Botanical Theatre and adjoining laboratories. Professor Joseph Barcroft presided at the luncheon with Professor O. Frank of the University of Munich on his right, Sir John Rose Bradford on his left, and Professor Ivan Pavlov facing him. The large company present included also Sir Humphry Rolleston, Regius Professor of Physic, Sir Archibald Garrod, Sir Charles Sherrington, Sir F. Gowland Hopkins, Professor H. R. Dean, Dr. W. E. Dixon, and Mr. J. H. Widdicombe, Senior Tutor of Downing. Professor Barcroft reminded the visitors that the Physiological Society was an informal and friendly body, whose members met chiefly to discuss work not yet ripe for publication. On this happy occasion, to celebrate the memory of the founder of modern physiology, the members welcomed their distinguished colleagues from abroad, and were delighted to have an opportunity of saying how much their writings and discoveries were appreciated in this country. After Professor A. V. Hill had given an account of the arrangements proposed for the Physiological Congress at Boston in August, 1929, the serious business of the afternoon began.

#### THE ROYAL SOCIETY CONVERSAZIONE.

The rooms of the Royal Society at Burlington House were filled with some interesting scientific exhibits for the usual spring *conversazione* on May 17th, when Sir Ernest Rutherford, O.M., Hon. F.R.C.P., President of the Society, received the guests, among whom were many of the delegates to the Harvey tercentenary celebration. Although there were many novelties to be seen, the repetition of some old experiments also drew interested groups; for example, there were some experiments in stereoscopic vision which were described in Dr. Robert Smith's *Opticks* in 1738, and again Faraday's studies of the crispations formed on liquids lying on vibrating surfaces were repeated by Sir William Bragg. The Royal Botanic Gardens at Kew sent for exhibition specimens of the plants yielding chaulmoogra oil, which is used in the treatment of leprosy. This oil is obtained from the seed of species of *Taraktogenos* and *Hydnocarpus*, tall trees occurring in the dense forests of India, Burma, and Siam. The British Mosquito Control Institute demonstrated the life-histories of various species of British mosquitos and the methods employed for controlling them. The Rothamsted Experimental Station

illustrated the biological control of insect pests and noxious plants. Something was shown of the attempt now being made to control the European earwig in New Zealand by the introduction in that country of its European parasitic foes, and the destruction of noxious plants by insects which attack them. Another exhibit of interest consisted of marine animals and bottom deposits obtained by the *Discovery* expedition. These were a collection of squids; crustaceans, and fish illustrating the development of luminous organs in pelagic animals, also the cores of deep-sea oozes, obtained with a new form of bottom-sampling apparatus, and preserved in the tubes in which they were collected. The Marine Biological Association showed a submarine photometer apparatus which has been used on its trawler to a depth of 70 metres. The Department of Zoology of the British Museum contributed some very interesting natural history exhibits. One of these showed a portion of the intestinal wall of a whale heavily infected with acanthocephalan worms. It was mentioned that of a school of killer whales recently stranded in Scotland, every individual was found to be infected with this parasite, but even when the intestine was almost blocked by the worms the whales appeared to be in good condition. Other specimens were the giant shipworm (*Kuphus arenarius*), which was obtained in the Solomon Islands, and anatomical preparations of the ostrich and allied birds to illustrate the structure of the feathers and the arrangement of bones and muscles of the wing, and to show that this family of birds are derived from ancestors that had not acquired the power of flight. Lord Rayleigh demonstrated how the peacock's feather fades if exposed to ultra-violet light, the green changing to blue, and the colour disappearing altogether with long-continued exposure, and Dr. L. J. Spencer showed the brilliant fluorescence of fluor spar and certain other minerals when exposed to this radiation. Dr. R. J. Ludford brought from the laboratories of the Imperial Cancer Research Fund a number of microscope exhibits to illustrate cell structure and intravital staining in tumour-bearing animals. He stated that mice given 1 c.c.m. injections subcutaneously of 1 per cent. trypan blue at intervals of a few days could be kept alive for several weeks. Within some of the cells, such as those of the kidney and liver, the dye collected in the form of diaplets in that part of the cytoplasm which coincided with the position of the Golgi apparatus. Areas of necrosis in transplanted tumours stained readily. There was a slight accumulation of dye in living sarcoma cells, but not in living carcinoma cells. Finally, there was a remarkable exhibit from the School of Pharmacy of the Pharmaceutical Society of Great Britain, consisting of specimens of the animal materia medica of the seventeenth century. At that time entire animals, as well as parts and excretions of animals, were largely used medicinally. In the *London Pharmacopoeia* of 1627 the bloods of fourteen animals, including that of man, were included. The Pharmaceutical Society recently came into possession of a number of these specimens, and some of the rarest and most interesting were shown. These included powdered mummy, which was supposed to resist gangrene; human skin, probably employed as a ligature; powdered shark's teeth, used for scorpion bites; the ends of tails of scorpions, given as a diuretic; callosities on the knees of horses, used for epilepsy; human blood, given as a sudorific and diaphoretic; calculi from the human bladder, given for stomach trouble; and human skull, powdered, considered good for epilepsy. During the evening Dr. Stanley Kemp gave an account of whaling in the Antarctic, with lantern illustrations of the methods used and of the scenery in the dependencies of the Falkland Islands.

### A BIBLIOGRAPHY OF HARVEY.

THE tercentenary of the publication of Harvey's *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus* has been piously commemorated under the auspices of the Royal College of Physicians of London, of which, to quote from Munk's *Roll*, he was "the brightest ornament"; but bearing in mind the proverb "*littera scripta manet*," there is every reason to welcome the three volumes which have most appropriately appeared to render the celebrations com-

plete, and especially Mr. Geoffrey Keynes's beautifully printed *A Bibliography of the Writings of William Harvey, M.D., Discoverer of the Circulation of the Blood*.<sup>1</sup> This fine product of the Cambridge University Press by a Cambridge graduate is so extraordinarily complete that some might like to imagine some inspiration from the late Sir William Osler, in whose study the first entry in the *Bibliography* was made on February 12th, 1927. There are five sections, giving detailed accounts of the Harveian writings, with interesting information about the actual resting places of the rare editions. As is only natural and right, nearly half the volume is occupied with the *De Motu Cordis*; then the *De Circulatione Sanguinis* (1649), or the two letters to John Riola the younger, and the *De Generatione Animalium* (1651) are similarly described. The fourth section, *Omnia Opera*, deals with publications of his collected works, and the fifth section, *Miscellanea*, contains notices of the necropsy on the famous Thomas Parr, reputed to be 153 years old, Sir George Paget's publication of a letter from Harvey to Samuel Ward, the Master of Sidney College, Cambridge, letters subsequently made public by Dr. J. H. Aveling and Dr. S. Weir Mitchell, and the well-known *Protections*, or notes for his Lumleian Lectures of 1616, brought out as an autotype reproduction by the College of Physicians in 1886. There is, in addition, an index of the recorded copies, the British Museum, with 35 entries, leading the College of Physicians of Philadelphia, which has 31.

Each section is introduced by a bibliographical preface full of scholarly lore—for example, the details of the cancelled title-page of the *De Circulatione Sanguinis*—and there are a number of well-executed illustrations and reproductions of title-pages. The *De Motu* and the *De Generatione Animalium* were both translated into English for the first time in 1653, but the responsible hand is unknown, and the suggestion that it was that of Dr. Martin Llewelyn, whose dedicatory poem to Harvey appears at the beginning of the latter translation, has not any evidence in its favour. The first English translation of the *De Motu Cordis* has just been edited by Mr. Keynes and issued by the Nonesuch Press. Of the first edition of the *De Motu* 17 copies have been tracked down; its Latin text has been printed twenty times, the last occasion in ordinary type being in 1824; but the College of Physicians has now had 250 copies of a photographic facsimile of the original edition prepared to commemorate the tercentenary.

### ROYAL MEDICAL BENEVOLENT FUND.

At a recent meeting of the committee forty-nine cases were considered and £659 voted to forty-one applicants. Since the beginning of the year £2,862 has been made in grants to urgent cases of distress. The demands for help increase; subscriptions are very urgently needed, and should he sent to the Honorary Treasurer, Sir Charles Symonds, 11, Chandos Street, Cavendish Square, W.1. The following are notes on a few of the cases relieved at the last meeting.

M.D.Durl., at the age of 76, with his wife blind and suffering from cancer, and without a penny saved, suddenly found himself out of employment. No provision had been made for old age, as since 1912 he had not been able to earn more than £300 a year. Before then he had educated two sons for the medical profession; one died during the war, and the other is delicate and is himself struggling to keep going. There were also two daughters to be educated. He will apply for the old age pension. The Fund voted £40.

Widow, aged 69, of L.R.C.P. and S.Ed. The applicant's husband died of cancer, leaving her penniless. He had been a salaried assistant, and on his decease the widow received only £35, the salary due to his death. The sale of furniture and a small gift of £20 had brought her total capital up to £150. The applicant is now living with a niece, the wife of a clergyman, who has only his stipend and is unable to support her. Voted £25.

Widow, aged 77, of M.R.C.S. Since her husband's death in 1884 the applicant has maintained herself as companion-housekeeper, but at 77 she is unfit for work, and her only income is the old age pension of £26 a year. Voted £35.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

<sup>1</sup> *A Bibliography of the Writings of William Harvey, M.D., Discoverer of the Circulation of the Blood, 1628-1928*. By Geoffrey Keynes, M.A., M.D., F.R.C.S. London: Cambridge University Press 1928. (8 x 10½, pp. xii + 67; 8 illustrations and 12 reproductions of title-pages. 21s. net.)

## THE LESSONS OF RARE MALADIES.

ANNUAL ORATION BEFORE THE MEDICAL SOCIETY OF  
LONDON BY SIR ARCHIBALD GARROD.

THE Annual Oration before the Medical Society of London was delivered on May 21st by Sir ARCHIBALD GARROD, K.C.M.G., D.M., F.R.S., whose subject was the lessons of rare maladies. Mr. HERBERT W. CARSON, President, was in the chair.

SIR ARCHIBALD GARROD said that in rare diseases were to be found the keys to not a few dark places in physiology and pathology. At the time of the First Empire, when the French universities were in the melting-pot, there were established in some of the medical schools professorships for the exposition of rare cases and diseases; and in the *Dictionnaire des Sciences Médicales* (1813) there was an article by Fournier on rare cases which extended to 120 pages. In British medical journals and transactions the speaker had found only two addresses on this subject—a series of Bradshaw Lectures by Sir James Paget in 1882, and a previous oration to the Medical Society by Sir Jonathan Hutchinson in 1889. Paget observed: "We ought not to set them [rare cases] aside with idle thoughts or idle words about 'curiosities' or 'chances.' Not one of them is without meaning; not one that might not become the beginning of excellent knowledge, if only we could answer the question—Why is this rare? or, being rare, why did it in this instance occur?" The study of what might be styled Nature's experiments was of special value, and many lessons which rare maladies taught could hardly be learnt in other ways.

There were two preliminary questions at the outset: Was it needful to draw a dividing line between rare cases and rare diseases? and What was meant by a rare disease? The answer to the first question was in the negative. Any example of a rare disease was a rare case, and a rare syndrome might be due to a lesion of a common kind in an uncommon situation. With regard to the second question, he did not propose to include in the category maladies which were common in hotter countries, but rare or absent from our own, nor infective diseases of lower animals rarely met with in human subjects, nor maladies the common occurrence or rarity of which depended upon the prevalence or absence of dietary defects. The truly rare maladies touched upon in this oration were such as were seldom seen in men living on any part of the globe or under any conditions of life. As to the criterion of rarity, he took it that between those common illnesses which went far to fill the hospitals and those so uncommon that the recorded examples could be counted upon the fingers every degree of rarity was represented; yet it seemed to him that the bulk of diseases fell into one or other of the more extreme categories, and that comparatively few were "somewhat rare."

*Departures from Type.*

One of the chief reasons why rare maladies could teach so much was because they called attention to the ordinary things otherwise accepted as a matter of course. We took for granted our own asymmetry—regarded it as natural that the liver should lie to the right and the spleen to the left. A case of transposition of viscera set us thinking, pondering as to the underlying cause of the more usual arrangement. Many rare maladies had as their underlying causes more or less abrupt departures from type such as were usually spoken of as mutations, which were transmitted to offspring, either as dominant or recessive characters. Such departures often threw light upon problems of heredity, on the development of the body, or of the living processes of which the body was the seat, and on the liabilities of individuals to special forms of disease. Some unfavourable mutations were anomalies of structure, manifesting themselves as malformations, such as claw-hand or excess of

digits; others were functional mutations, and these, like interferences with a delicate and complicated machine, might bring about results which, however undesirable, threw valuable light on normal working. Thus from the study of some rare maladies much knowledge was gained of diathesis, the constitutional factor in the causation of disease. Idiosyncrasies also—those special sensitivities to certain protein substances, to pollens, foods, and drugs—had a share in the causation of some rare syndromes.

*Addison's Researches.*

The orator took as his first example the least rare of rare maladies, Addison's disease, specially to call attention to Addison's pamphlet (1855), which was a model of scientific clinical medicine, controlled by morbid anatomy. In the preface to that epoch-making monograph in which he set forth his researches Addison described it as "a first and feeble step towards inquiry into the functions and influence of the adrenals, suggested by pathology": for it was clear to him that it was the seat and not the nature of the lesions which determined the symptoms. From that "first and feeble step" had grown up our knowledge not only of the functions of the adrenals, but also of the other endocrine glands, and of the hormones which they secreted. As more had been learned about them they had been recognized as the regulators of the metabolism of the tissues, also of height and weight, temperature, and blood pressure. It had become increasingly evident that the several ductless glands, acting, some as mutual opponents and others as allies, formed a balanced mechanism, which set limits to the various functions, and by readjustments of which the phenomena of puberty and of the climacteric were brought about. The most recent advances in endocrine studies; the isolation and synthesis, first of adrenaline itself, and lately of thyroxine; the study of their physiological actions, and the utilization of insulin, might rank among the greatest achievements of medical science, and all might be traced back, directly or indirectly, to Addison's researches.

Passing to inborn errors of metabolism, the orator mentioned alcaptonuria, a rare anomaly, which behaved as a characteristic Mendelian recessive character, and was wont to occur in several brothers and sisters, whose parents were usually normal but were in a large proportion of cases first cousins. By the study of this malady from the standpoint of chemistry, and by the administration to its subjects of a variety of aromatic compounds, much light had been thrown upon the katabolism of proteins; it had also shown how a metabolic product might have the power of staining certain living tissues in a selective manner, and, further, that, a trifling deviation from the normal in metabolism and the presence in the tissues of small quantities of an intermediate product, normally destroyed, might so lower the resistance of tissues that, after the lapse of many years, there was developed, under the stress and strain of daily life, a characteristic form of osteo-arthritis. Another still rarer malady was congenital porphyria, or haematoporphyria, which stained the bones a deep brown colour, and had taught us much regarding the action of light upon the living organism.

*Tissue Anomalies.*

The orator's next example was taken from that group of tissue anomalies which included the familial-hereditary affections of the nervous and muscular systems to which Gowers gave the name of "abiotrophies." These illustrated a point upon which Hutchinson laid much, perhaps too much, stress—namely, the affinities between morbid states and their tendency to merge into each other. Thus in a particular family tissue anomalies might crop up in different members, in one some form of muscular atrophy, in another myotonia atrophica. The muscular dystrophy and myotonia had in the observed cases been limited to the collaterals of one generation of a family, seldom developing before the age of 25; but cataract, which was associated with the syndrome, had been traced back through four or five generations. Some recent investigators held that the underlying factor in the disease under discussion was a widespread defect of the endocrine glands, and that what was a pluriglandular syndrome. It

might well be that other affections of this group, the abiotrophies, would prove to be local manifestations of much wider maladies, and that the link between the calcareous deposits and the digital anomalies in myositis ossificans might be found in a generalized defect of the mesenchymatous tissues, of which these were merely the most conspicuous signs.

He next touched upon the very rare and curious disease first described by Gaucher in 1882, and known by his name—a form of enlargement of the spleen, met with in a child, and characterized by the presence in the splenic tissue of numbers of large hyaline cells which stained but feebly. Before long it was realized that this was no form of malignant growth, and that the changes were by no means limited to the spleen, the liver becoming greatly enlarged and the haemopoietic tissue generally being involved. In recent years it had been shown that the peculiar Gaucher cells, found in all the affected parts, owed their swollen and hyaline appearance to the presence in them of a chemical substance, kersasin, a member of the class of galacto-lipins. One of the latest theories was that here one had a perversion of the metabolic process, and that kersasin was a product of abnormal metabolism. The subjects of such maladies as the abiotrophies and Gaucher's disease furnished striking examples of constitutional liabilities. It was because they were uncommon individuals that they were predestined to suffer—in other words, the patient rather than the malady was rare.

#### *Maladies Still Obscure.*

In conclusion, the orator spoke of some rare maladies the lessons of which had been learnt only in part or not at all. The syndrome known as intermittent hydrarthrosis had features which might be described as uncanny. Effusion into the knee-joint here recurred with a regularity comparable to that of some forms of malaria, and was clearly not connected with the life-history of any parasite. An exactly similar periodic hydrarthrosis was sometimes met with in cases of arthritis of various kinds. There was undoubtedly a connexion between the cutaneous lesions of the erythema group and affections of the joints—witness the familiar serum sickness. Again, periodicity was met with in other maladies of the anaphylactic group, in erythemata occasionally, in asthma often, and in Henoch's purpura almost always; but in none of these conditions was there any such accurate periodicity as in hydrarthrosis. The most likely explanation was that each attack desensitized the patient for a time, at the expiration of which the trouble recurred.

Another very uncommon syndrome was sulphæmoglobinæmia, clearly an acquired malady, with no indication of family or hereditary occurrence. Its chief problems still awaited solution. Chloroma was another rare malady which presented important unsolved problems. Another of the most obscure of rare diseases was that malady involving the bone marrow, of which the copious excretion of the Benico Jones protein was the diagnostic sign. That weird mixture of infantilism and premature senility which Hastings Giffard described under the name of "progeria," and the developmental anomalies of bony structures, of which achondroplasia, oxycephaly, and hypertelorism might be cited as examples, had not yet revealed their secrets, but would repay investigation. Of all these it might be said that they tended to prove the truth of Harvey's dictum that "Natura is nowhere accustomed more openly to display her secret mysteries than in cases where she shows tracings of her workings apart from the beaten path." The orator hoped that there would always be some who would seek to guess the riddles and to learn the lessons of the rarer maladies.

At the annual meeting of the Medical Society of London, which preceded the oration, Dr. John Walter Carr was elected president for 1928-29, Dr. J. E. H. Roberts a new vice-president, and Dr. Anthony Feiling and Mr. R. Davies-Colley honorary secretaries. It was stated that the society now numbered 626 Fellows, including 15 honorary Fellows. The vote of thanks to Sir Archibald Garrod for his oration was proposed and seconded by Sir James Berry and Dr. J. W. Carr respectively.

## THE BRITISH PHARMACOPOEIA.

### PROPOSALS FOR A STANDING COMMITTEE.

THE report of the subcommittee on the *British Pharmacopœia*, appointed by the Committee of Civil Research at the instance of the General Medical Council, was published on May 17th.<sup>1</sup> In its fifty-seven pages it gives a brief account of the evolution and present position of this official publication, records the criticisms directed against the existing machinery for its production and revision, and submits a series of proposals for its future conduct and constitution. The subcommittee, which came into being on July 18th, 1926, was directed in its terms of reference:

To make inquiries, to collect information, to receive evidence, and to make recommendations on the question whether it is desirable to make any, and if so, what, alterations in the existing law or practice relating to the preparation or publication of the *British Pharmacopœia* and to its adaptation to the requirements of the British Empire.

The members of the subcommittee were as follows:

The Right Hon. H. P. Macmillan, K.C. (Chairman).  
The Right Hon. Lord Dawson of Penn, G.C.V.O., M.D.  
Sir Donald MacAlister, Bt., M.D., President of the General Medical Council.  
Dr. H. H. Dale, F.R.S., Director of Department of Biochemistry and Pharmacology, Medical Research Council.  
Mr. Edmund White, Past-President of the Pharmaceutical Society of Great Britain.  
Dr. H. G. Dain, Chairman, Conference of Representatives of Local Medical and Panel Committees, British Medical Association, 1919-24.

The subcommittee's task fell naturally into two main branches—consideration of the legal position of the *Pharmacopœia* and consideration of the machinery for its compilation and revision in the light of current difficulties. So far as the first question is concerned, it concludes that no change involving legislation is necessary, and the bulk of the proposals put forward therefore relate to the method by which it is considered the *Pharmacopœia* should be produced, and the considerations which should govern its composition. In view of the fact that no change in the law is suggested, the subcommittee states: "We recognize that . . . the carrying into effect of our recommendations will depend on their acceptance by the General Medical Council, but we are hopeful that the scheme which we propose will commend itself to the Council." The scheme referred to provides for the appointment by the General Medical Council of a selection committee consisting of persons nominated by the Council itself, by the three pharmaceutical societies, and by the Medical Research Council. This selection committee will nominate a *Pharmacopœia* Commission, a permanent body, which will be charged, under the general direction of the General Medical Council, with the actual work of preparing future issues of the *British Pharmacopœia*. Provision is made to secure the co-operation, where it is desired, of representative bodies in the Dominions and in India.

#### *Difficulties in Securing Co-operation.*

At this point we may recall the chain of events which led to the institution of the inquiry now completed. At the autumn meeting of the General Medical Council in 1925 it was announced that preparations had been made to proceed with a revision of the *British Pharmacopœia*, 1914. Communications had been addressed to the various Governmental authorities interested, at home and in the Dominions, and to universities and medical corporations in this country, inviting relevant suggestions, while the Pharmaceutical Society of Great Britain had been asked to co-operate by nominating members of a pharmaceutical advisory committee and a committee of reference in pharmacy. The Council, therefore, proposed to proceed on the lines which had governed the earlier revisions. Difficulty was experienced, however, in securing assurances of the requisite expert assistance, and it became clear that pharmacists generally objected to the perpetuation of a system which involved the performance by them of a large part of the work required, while the responsibility for editing the *Pharmacopœia* was retained by a committee of the General Medical Council. An interesting account of

<sup>1</sup> Cmd. 3101. London: H.M. Stationery Office or through any bookseller. 1928. 1s. net.

the position by Professor A. J. C. (he then held the chair of College, London) was published in the *British Medical Journal* on January 2nd, 1926 (p. 30). In it he gave a critical analysis of the methods employed in the preparation of the *British Pharmacopoeia* and of the *United States Pharmacopoeia*, the tenth revision of which had just been completed. As a result of the criticisms directed against its procedure, the General Medical Council convened a conference between the members of its Pharmacopoeia Committee and representatives of various medical, scientific, and pharmaceutical bodies, and at a meeting on February 23rd, 1926, a free discussion took place. The outcome of these proceedings was the appointment of the subcommittee whose report is now under review.

#### *Defects in the Present System.*

This document surveys the evolution of the *British Pharmacopoeia* from the earliest times, giving particular attention, of course, to the part played by the General Medical Council in the execution of its responsibility for the production of this work under the Medical Acts of 1858 and 1862. A review is given of the methods of preparation adopted for each successive edition from 1864 to 1914, in the course of which period the system now in the melting-pot was gradually built up. Reference is then made to certain developments which have taken place since 1914, such as the passing of the Therapeutic Substances Act, 1925, and the subcommittee proceeds to comment on the machinery of the General Medical Council in this period, stating that:

"The functions of the Pharmacopoeia Conference and the committees of reference set up to assist in the preparation of the fifth *British Pharmacopoeia* came to an end on its publication. The Pharmacopoeia Committee of the General Council continued to meet at intervals, and presented half-yearly reports dealing with matters referred to above (e.g., the Therapeutic Substances Act), and any other topics arising which affected the *British Pharmacopoeia*. But no systematic or continuous work was undertaken with a view to the next revision, and no digests of material were compiled. . . . In 1921 the Pharmacopoeia Committee received an offer of co-operation in matters of common pharmaceutical interest from the Chairman of the Committee of Revision of the *United States Pharmacopoeia*, which was cordially accepted, and this was followed by the transmission of advance copies of material compiled by the United States Committee dealing with proposed omissions and additions, drafts of new monographs and the like."

After giving a survey of the more recent events mentioned above the subcommittee submits a detailed study of the legal status of the *Pharmacopoeia* throughout the British Empire, and goes on to review the criticisms of the existing regime placed before it by interested parties. This criticism, the report states, was directed against both "the method of production and the resulting product." With regard to the criticism of what may be termed the non-expert status of the Council the subcommittee remarks:

"It was pointed out that the General Medical Council has a number of most important public duties, judicial and administrative, to perform, and that its members are selected not with a view to their fitness or capacity to take part in the production of the *British Pharmacopoeia*, which is only one of their functions among others, but rather because of their general ability and professional standing."

The subcommittee found that one of the main objections to the existing system came from those who had assisted in the production in the past, and who were dissatisfied with the status accorded them in relation to their work. This was not confined to the pharmaceutical societies: the complaint was general that the experts in the various branches of science whose collaboration was essential did not enjoy a responsible status such as they claimed their services merited.

The report proceeds to consider the nature of the *Pharmacopoeia*, introducing its discussion with the note:

"In early times pharmacopoeias were little more than descriptive lists of medicines in use by the profession, and their compilation was generally the work of medical men. But a modern pharmacopoeia must be much more than this. It must contain not only a carefully scrutinized list of current drugs of repute, but also authoritative standards whereby the purity and efficacy of these drugs may be tested."

The definition suggested by the British Medical Association\* is quoted:

"The *Pharmacopoeia* should contain, so far as practicable, all those drugs and preparations which experience shows to be in common use by medical practitioners and which in the interest of the public require a standard method of preparation, or a standard of strength, or a standard of purity; provided that such drugs and preparations have a therapeutic or diagnostic value, or are pharmaceutically necessary."

The members of the subcommittee came to the conclusion that it was unnecessary for them to discuss in detail the sphere of the *Pharmacopoeia*, as this was a matter for those charged with the preparation of future editions, and they therefore concentrated their attention on the question of securing that this work should be undertaken by those best fitted for it. The result of their deliberations on this matter has already been indicated, and is given in greater detail in the summary printed below. With regard to the period of publication, it is suggested that the revision should be so arranged that the successive issues of the *British Pharmacopoeia* should appear in the middle of the intervals of the issues of the *United States Pharmacopoeia*, which is already published every ten years. Considerable weight is attached to the establishment of an adequate secretariat with suitable staff and equipment, in view of the importance of co-operation with other parts of the Empire and with the United States, and the growing international aspect of pharmaceutical enterprise. The report indicates that the subcommittee has been assured that the important work of research, often of a voluntary nature, which has so frequently been provided in the past by experts with laboratory facilities at their disposal, will be given to the proposed Pharmaceutical Commission increasingly, if it is established.

In making investigation into the question of the adaptation of the *Pharmacopoeia* to the needs of the Empire communications were addressed to a number of the Dominions and Dependencies, and for the most part their answers indicated that they were either satisfied with the existing system or were prepared to accept a revised *Pharmacopoeia* without representation on the body responsible for its production. Various Canadian interests, however, held that Canada should have a voice in revision, but the Canadian Government, although twice approached, did not find it possible to appoint an authoritative representative to discuss with the subcommittee the best means of adapting the *British Pharmacopoeia* to Canadian requirements. General suggestions for adapting the *Pharmacopoeia* to regional needs are given in the report.

#### *Conclusions and Recommendations.*

The report gives the following summary of the principal conclusions and recommendations of the subcommittee:

(i) That it is not necessary or desirable to make any alterations in the existing law relating to the preparation or publication of the *British Pharmacopoeia*.

(ii) That the General Medical Council set up forthwith a Selection Committee to be charged with the duty of selecting persons to form a new body to be designated "The Pharmacopoeia Commission."

(iii) That the composition and functions of the Selection Committee be as follows: (a) The Selection Committee should consist of four persons nominated by the General Medical Council, three persons nominated jointly by the Council of the Pharmaceutical Society of Great Britain, the Council of the Pharmaceutical Society of Ireland, and the Council of the Pharmaceutical Society of Northern Ireland, and two persons nominated by the Medical Research Council; the representatives in each case to be chosen by the nominating body either from among or from outside its membership. (b) The chairman of the Selection Committee should be appointed by the General Medical Council from among their four representatives. (c) The Selection Committee so appointed should select persons representative of the various appropriate departments of knowledge and experience to form the Pharmacopoeia Commission. (d) The number of persons selected to form the Pharmacopoeia Commission should not be prescribed, but should be left to the discretion of the Selection Committee, who should have power from time to time to select additional persons for permanent or temporary membership, including representatives

\* A "watching" committee was appointed by the British Medical Association in July, 1926; a memorandum was prepared for presentation to the subcommittee, and evidence on behalf of the Association was given by Dr. J. W. Bone and Dr. G. C. Anderson, Deputy Medical Secretary.

of India or the Dominions. (c) The Selection Committee should submit to the General Medical Council for approval the name of one of the selected persons to be chairman of the Commission.

(iv) That the manner of appointment, composition, and functions of the Pharmacopoeia Commission should be as follows: (a) The Pharmacopoeia Commission should be appointed by the General Medical Council, its members being persons whose names are submitted to the Council by the Selection Committee. (b) The Pharmacopoeia Commission should be a permanent body with an office and suitable secretariat, and the work of collecting and collating material, preparing reports, and conducting correspondence with a view to the preparation of future issues of the *Pharmacopoeia* should be carried on continuously. (c) The actual work of preparing future issues of the *British Pharmacopoeia* should be undertaken by the Pharmacopoeia Commission under the general direction of the General Medical Council; on each revision the completed volume should be submitted by the Commission to the General Medical Council for approval; and when approved it should be issued as heretofore with the authority of the General Medical Council. (d) The Pharmacopoeia Commission should have power to appoint subcommittees, and to include among the members of such subcommittees experts in any particular branch, whose assistance may be desired, although they may not be members of the Commission.

(v) That in future the *British Pharmacopoeia* should: (a) Be revised and reissued at stated intervals of ten years, supplements being issued between the successive editions as required. (b) Contain only standard drugs in general use throughout the Empire.

(vi) That where it is desired in any part of the Empire to sanction the use of particular local drugs, or alternative preparations not included in the *British Pharmacopoeia*, this should be left to be effected by the Governments concerned by the issue of local supplements or addenda.

(vii) That the Governments of the Dominions and of India be requested by the General Medical Council, through the appropriate channels, to set up or cause to be set up responsible and representative committees to co-operate with the Pharmacopoeia Commission in the revision of the *British Pharmacopoeia*, if they desire and are willing to take part in the work.

(viii) That, at any rate until the results of the publication of the next revision are seen, the funds necessary for carrying on the work of the Pharmacopoeia Commission be provided by the General Medical Council, who should receive the proceeds of all sales of the *Pharmacopoeia*, a separate account being kept.

## Scotland.

### William Mackenzie Memorial Medal.

The first award of the recently instituted William Mackenzie Memorial Medal, "In recognition of valuable contributions to ophthalmology," will be made to Dr. A. Maitland Ramsay, honorary director, James Mackenzie Institute for Clinical Research, St. Andrews; consulting ophthalmic surgeon, late surgeon, Glasgow Royal Infirmary and Ophthalmic Institution. The presentation will take place in Glasgow in the autumn, on a date to be arranged, and on that occasion Dr. Ramsay will deliver an address.

### Chair of Genetics at Edinburgh.

Dr. F. A. E. Crew has been appointed by the University Court of Edinburgh University to be professor of animal genetics and director of the University Department of Research in Animal Breeding under an ordinance founding this chair, which received the approval of His Majesty on May 7th. The chair was founded by a donation from Lord Woolavington, supplemented by a grant from the International Education Board, New York. Professor Crew is a graduate of Edinburgh University, where he took the degree of M.B. in 1912. During the war he served with the R.A.M.C. in India and France, and on demobilization took up a post as assistant in the Natural History Department of the University. In 1920 he was appointed director of the newly-formed Animal Breeding Research Department, then housed in High School Yards. He has organized much research and contributed many papers to the literature on this subject. In 1926 Dr. Crew was William Withering lecturer at the University of Birmingham, and in 1928 Milroy lecturer at the Royal College of Physicians, London. Among the works which he has published have been volumes under the titles of *Animal Genetics*, *Organic Inheritance in Man*, and *Heredity*.

### Conference of Health Visitors.

The Scottish Association of Health Visitors, Women Sanitary Inspectors, and School Nurses held the 9th annual conference in the City Chambers, Edinburgh, on May 12th, when Lady Leslie Mackenzie presided. Dr. William Robertson, medical officer of health for Edinburgh, who welcomed the delegates on behalf of the Town Council, said that within the last twenty years the task of the visitor had become less depressing than it used to be because social conditions were gradually improving and the people were taking a much greater interest in themselves and in their families, and housing conditions were being remedied. The work did not now consist merely in visiting slums, but it was still the duty of health visitors to reduce the number of apathetic and indolent people who paid no heed to the simple things that mattered in regard to health. In the next thirty years most of the efforts made by health visitors would be preventive rather than remedial. Dr. Ernest H. Connell opened a discussion on psychology and nursing, and claimed that they lived in a psychological age. Dr. David McKail (Glasgow) said that in some quarters of Glasgow the attitude of the people was to do nothing in the presence of illness, and to take up the bad mental attitude of saying, "It is in the family." The health visitor had a big work in front of her in helping to educate such people. Councillor Mrs. Millar (Edinburgh) said that the juvenile delinquency committee had found that in practically no family where a health visitor was attending was a juvenile delinquent found. The delegates in the afternoon visited several of the hospitals of the city. On the previous evening they had attended a reception in the City Chambers, given by the Corporation, where they had been received by Bailie Hay in the absence of the Lord Provost.

### Teeth of the Working Classes.

At the annual meeting of the Edinburgh Dental Hospital and School Professor P. S. Lelean moved the adoption of the directors' report. He said that national decadence was shown in no way more decisively than in the condition of the teeth. From 95 to 97 per cent. of school children in Britain suffered from dental caries. Referring to 60,000 recruits for the army seen annually, the official report declared that on an average six teeth were decayed, of which two needed immediate extraction and four required treatment to make the recruit dentally fit. This was the condition of the mouth in the young, relatively vigorous recruit; what, then, must be the condition of a debilitated, ill-nourished mother of the slums? The Edinburgh Dental Hospital had made a magnificent attempt to stem this tide of decay and to put right the appalling condition of the teeth of the working classes. Last year in the hospital 12,000 teeth had been conserved, 1,600 dentures had been fitted, and 22,000 treatments had been given by the 132 students attending the school. The speaker considered that it was pathetic that the total contributions of the public in Edinburgh would only suffice to maintain the institution for one week in the year, and that £8,000 was still required to pay for the additions to the hospital which had been opened last year.

## England and Wales.

### Training and Employment of Midwives.

The Minister of Health has appointed a departmental committee whose terms of reference are: "To consider the working of the Midwives Acts, 1902 to 1926, with particular reference to the training of midwives (including its relation to the education of medical students in midwifery), and the conditions under which midwives are employed." The committee is appointed with the concurrence of the Central Midwives Board, and its appointment forms part of the measures for dealing with the problem of maternal mortality and morbidity which were referred to by the Minister when introducing the Estimates of the Ministry of Health in the House of Commons on May 15th. The members of the committee are as follows: Sir Robert

Bolam, M.D. (chairman), Dr. J. W. Bone, Dame Janet M. Campbell, M.D., Lady Cynthia Colville, Dr. W. A. Daley, Dr. J. S. Fairbairn, Dr. T. Eustace Hill, Miss Alice Gregory, Mr. A. B. MacLachlan, Dr. F. N. Kay Menzies, Mrs. Bruce Richmond, and Miss Katherine J. Stephenson. The secretary will be Mr. W. H. Howes of the Ministry of Health, to whom all communications relating to the work of the committee should be addressed.

#### King Edward's Hospital Fund for London.

The Prince of Wales presided at the annual meeting of the King Edward's Hospital Fund for London, held at St. James's Palace on May 15th, to which a brief reference was made in our last issue (p. 883). After reading a message from the King, in which His Majesty expressed his gratification at the results achieved by the special distribution of £255,000 received from the estates of the late Mr. and Mrs. John Wells, which had helped the hospitals of London to provide 1,600 additional beds and to meet other urgent requirements, the Prince of Wales stated that the accounts showed a better result than had been anticipated in November, when the League of Mercy announced that it would give the Fund £17,000 instead of £15,000, so that the ordinary distribution could be increased to £247,000. This year they had already had a gift of £10,000 for general purposes from an anonymous donor, and their capital had been increased by a donation of £10,000 from Mr. J. J. Crosfield. Referring to the statistical report on the hospitals of London His Royal Highness said the total voluntary contributions to the 140 hospitals amounted to something like £1,800,000 a year. In the report, for the purpose of helping hospitals to control their expenditure by providing comparative figures of cost, quantities consumed were now given as well as money spent. The inquiry by the Pay Beds Committee into the question of hospital accommodation for the middle and professional classes was nearly finished, and the conclusions would be based on a study of pay beds as they now existed in London. Grants from the Wells legacies, which began in 1924, had for four years enabled the Distribution Committee to take each urgent scheme as it came along, at any time of the year, and give it a grant. In addition to other work, three new hospitals had been built and four had been rebuilt on new sites. In conclusion, the Prince referred to the loss the Fund had suffered by the deaths of Lord Cave, Sir William Church—who was a member of the council for twenty-seven years—and Sir John Craggs. Lord Revelstoke, honorary treasurer, presented the accounts, saying they had been able to carry forward £2,700 as a balance to next year, and gave an interesting account of the origin of the Wells legacies. The report of the general council submitted by the Earl of Donoughmore, chairman of the Management Committee, after referring to several matters already mentioned, stated that the total sum distributed during the last ten years, including all special payments, was £3,360,688. The British Charities Association again gave £15,000 last year, while an anonymous donation of £8,000 was received. Special consideration has been given to various aspects of the accidents problem, arising out of increased road traffic, and particular attention has been directed to the burden thrown upon hospitals provided to meet local needs by cases arising from this cause. The Fund is engaged in inquiries with a view to preparing practicable proposals to lay before a conference of the various parties concerned. A report on the new edition of the Fund's statistical report was approved. This edition is the first to be based on the new regulations under the revised uniform system of hospital accounts, and contains much valuable data relating to income, expenditure, and working costs in 139 institutions. The proceedings terminated with the moving of a vote of thanks to the Prince of Wales for presiding and for his continued interest in the Fund.

#### The Hospital for Sick Children and the Foundling Hospital Site.

The need for the reconstruction of the Hospital for Sick Children, Great Ormond Street, London, has been recognized for some time past, and consideration is being given to the question of securing a new site. Early this year the board of the hospital was approached by the

Foundling Estate Protection Association with the proposal that the Foundling Hospital site should be purchased jointly, the forecourt to be preserved as an open space for the public and the Children's Hospital to be rebuilt where the "Foundling" buildings now stand. Mr. Stanley Hall, F.R.I.B.A., has reported that to rebuild the Sick Children's Hospital on its present site would be attended with grave disadvantages as regards air, light, and health conditions generally, and at a general court of governors on May 16th it was stated that the Council of King Edward's Hospital Fund, in view of the architect's report, would raise no objection to efforts being made to secure a new site, provided that the board was satisfied with the prospect of securing adequate funds. A committee has been formed from the board of management and from the Foundling Estate Protection Association, which is in negotiation with the owners of the property, and if the result of these negotiations is satisfactory an appeal on a large scale will, no doubt, be launched. Almost the only critics of the scheme were described as those who advocate other plans for the exploitation of the Foundling Estate.

#### Prevention of Tuberculosis in Childhood.

In a memorandum of the tuberculosis group of the Society of Medical Officers of Health reference is made to a useful form of preventive work which has been adopted in Shropshire. Infective tuberculous women who are pregnant are admitted to a sanatorium until just before labour, when they are transferred to a special open-air ward at a maternity hospital. After her confinement the patient returns to the sanatorium, and the infant is sent for one year to the County Home for Ailing Babies, where four beds are reserved for these cases. Attempts are made at the end of the year to board out the babies for a further period with relatives of the patient. Emphasis is laid also in the report on the importance of tracing sources of infection, it being borne in mind that the notified case is often not the chief danger. Removal of potential patients from a source of infection is advocated, either, as in France, by the Graucher system, or by making use of a residential open-air school. Attention is called to the valuable work which the general practitioner can render as regards steps being taken for the prevention of infection, and also for the education of the lay public. A closer degree of co-operation is advocated between the tuberculosis department, the school medical department, and maternity and child welfare centres. The opinion is expressed that the prevention of tuberculosis would be facilitated by extending Insurance Act benefits to the dependants of the insured.

## Ireland.

#### Appointment of Dispensary Medical Officers in the Free State.

UNDER the Local Authorities (Officers and Employees) Act, 1926, a dispute has arisen between the Department of Local Government and Public Health and the South Cork County Board of Public Assistance with regard to the appointment by the latter body of a dispensary medical officer who was not one of its officials, and served under another health authority. In connexion with the matter the Local Government Department, in a letter to the local body, pointed out that as none of the existing medical officers in the employment of the Board was desirous of accepting the office, the vacancy should be reported to the Local Appointments Commissioners. In reference to the minute of the Board requesting the Minister to sanction the appointment of Dr. Nyhan, the Minister desires to state that he is unable to meet the wishes of the Board. If it were possible for the Board to nominate a particular officer from outside their area, a condition of affairs would arise that practitioners generally would be denied opportunity for preferment on grounds of their experience or attainments. After most careful consideration, the Minister has decided, in the general interests, that, where an appointment is not proposed from existing officers of a local authority, the making of the

appointment should be placed in the hands of the Local Appointments Commissioners, who have suitable machinery for assessing the relative merits and qualifications of eligible candidates.

#### Medical Benefits (Northern Ireland).

In the Northern House of Commons when a money resolution in connexion with the National Health Insurance Bill was proposed, Labour and Nationalist members urged the inclusion of medical benefits under the Act. Mr. Kyle (Labour) said that unless they got an assurance that such benefits would be included, he thought every measure of this kind should be opposed to the utmost. There was nothing impossible about the proposal, he said, and the Local Government Commission were within an ace of reporting in favour of it when they were stampeded by members opposite in favour of the dispensary system. He declared that under the present system there was an inducement to doctors to certify people who were not incapable of work. Mr. J. Devlin and Mr. Healy supported the proposal. Mr. J. M. Andrews, Minister of Labour, said that at the present moment it would be inadvisable to adopt the suggestion. There were special difficulties in connexion with the matter, and it would be very foolish, in the interests of the poorest of their people, to make any drastic decision. He did not think that the dispensary system was unpopular, and they must be careful that in doing away with that system they did not do the people an injury instead of a benefit. The resolution was agreed to, and the Bill was carried through its remaining stages and passed.

#### Return of Empty Medicine Bottles and Cases.

At Cavan Circuit Court, Messrs. Evans Sons Lescher and Webb, Ltd., Liverpool, sought to recover £26 9s. 9d., value of unreturned empties in connexion with the supply of medicines, the defendants being the Cavan Board of Health. A sum of £15 was lodged in court to meet the claim. Eighteen dispensary districts were involved, and sixteen doctors were in court. Dr. O'Rourke, Ballyconnell, said that dispensary doctors should not be asked to return empties. It was not in the terms of their appointment. There should be something in the nature of a clearing house. A decree was given for £24 7s. 9d., with £5 expenses.

## Correspondence.

### THE PATHOGENESIS OF ACUTE PRIMARY GLAUCOMA.

SIR,—In a paper on the relation between capillary pressure and secretion, published in the *Proceedings of the Royal Society*, May 29th, 1912, M. Flack and I stated that "the increased tension in glaucoma is due to increased imbibition and secretion of fluid, resulting from an altered metabolism of the ocular tissues, leading to compression of the veins, and to a rise in the capillary-venous pressure; and therefore intraocular pressure. . . . Acute glaucoma resembles an inflammatory condition in any other part of the body."

Dr. Maitland Ramsay, in his address published in the *British Medical Journal* of May 12th (p. 789), ascribes the disease to a toxin producing congestive changes—a similar view. He assumes that there is normally, both in the eye and in the glomeruli of the kidney, an excess of pressure sufficient to overcome the osmotic pressure of the plasma proteins and produce filtration. This is a view combated by me and my co-workers, M. Flack and J. McQueen. Duke-Elder, by his recent ingenious observations on the retinal veins and arterial pressures, has not, in my opinion, secured any evidence which proves his assumption of the existence of a capillary pressure much above that of the intraocular fluid.

Tamura, in Japan, recently has confirmed our view concerning the glomerular capillary pressure. The excess of this over that of the fluid in the Malpighian capsule does not suffice to produce filtration. The whole question of

capillary pressure and filtration is dealt with in a paper now ready for publication by James McQueen and myself. This will appear in the *British Journal of Experimental Pathology*.

By secretion of fluid we mean the control of the amount and nature of the fluid by the living cells and endothelial membranes. It is these which are altered by metabolic changes and toxins. It is not the push of a capillary pressure, but the penetrability of the endothelial membranes and the pull of the tissue cells, which is of first importance.—I am, etc.,

London, N.W., May 17th.

LEONARD HILL.

SIR,—The interesting lecture by Dr. Maitland Ramsay on the pathogenesis of acute primary glaucoma raises of necessity the problem of the genesis of the intraocular fluids. Let me quote:

" . . . . . 'hat the tissue fluids come from the . . . . . ugh the walls of the capillaries, and . . . . . that the intraocular fluids obey the same physico-chemical laws. He believes, therefore, that the aqueous humour is a dialysate, and has brought forward evidence to prove that it is neither a secretion nor a filtrate. His work has put the physiology of the intraocular circulation into line with the circulation in the body as a whole."

This seems to me to be going somewhat fast. I am afraid there are some hedges and ditches in the course, but I am ready to be instructed how to take them. Let me state the problems.

As regards the filtration theory, it rests on the belief that the pressure in the capillaries of the eyeball is a filtering pressure—that is, above 48 to 55 mm. of Hg. It is generally agreed that the intraocular pressure is somewhat lower, by 1 or 2 mm. of Hg, than the pressure in the retinal veins. Taking the intraocular pressure at 25 mm. of Hg, on the filtration theory there would be a loss of pressure (pressure gradient) between capillaries and veins of more than 22 to 28 mm. of Hg. Elsewhere in the body the loss of pressure between capillaries and veins is 1 to 2 mm. of Hg. Loss of pressure in the arteries is due to change of arterial lumen—its narrowing—and the main loss of arterial pressure in the body is in the arterioles. There is no evidence of any peculiarity in the lumen of the capillaries of the eyeball to make this enormous reduction of pressure between capillaries and veins. It seems more probable that the capillary pressure in the eyeball is 1 to 2 mm. of Hg above the vein pressure, as elsewhere in the body. Consequently no filtration pressure exists in the capillaries of the eyeball.

The secretory theory denied the existence of a filtration pressure. The mechanism of secretion remained more or less a mystery. Now we have the dialysis theory. A very notable experiment in dialysis was carried out by Abel, who passed the blood from an artery through collodion tubes to a vein, the collodion tubes being placed in a bath of saline. The saline solution is later analysed for the substances that have entered it from the blood by diffusion—amino-acids, etc. It will be noted that what enters the saline solution are the crystalloids it does not contain originally or contains in less concentration. Were the bath distilled water, all the various salts, etc., of the blood would pass through the collodion membrane.

It is attractive to think of the tissue fluid as an Abel's bath, and similarly with the aqueous humour of the eye. But the bath in the case of the eyeball must be renewed. Six cubic millimetres of aqueous fluid per minute is estimated to be made in the eyeball. Consequently six cubic millimetres of salt- or crystalloid-deficient water has to be made per minute in the eyeball from somewhere to allow of dialysis occurring; and perhaps more, because the six cubic millimetres estimate does not include what passes out through the canal of Schlemm and what may be absorbed into the capillaries of the eyeball, because if there is no filtration pressure in the capillaries of the eyeball, and the pressure gradient between capillaries and veins is 1 to 2 mm. of Hg, then the osmotic pressure of the blood in the capillaries is unbalanced practically, and water will pass into the capillaries of the eyeball from the aqueous humour.

I do not wish to undervalue the evidence gained by

experiments on haemorrhage. There the tissue cells mobilize water deficient in salts which passes into the capillaries to restore blood volume. But if in the case of the eyeball the ciliary processes, for example, produce a salt-deficient water, they might, it seems to me, just as easily produce a normal intraocular fluid; and now we are back again at a secretory theory. The most important hedge to be taken in the course is an accurate direct measurement of capillary pressure in the eyeball. But it is a pleasure to know there are workers in the saddle.—I am, etc.,

Stilesowen, May 12th.

JAMES M. McQUEEN.

### IMMUNITY FOLLOWING HERPES.

SIR,—Dr. Parkes Weber, for whose encyclopaedic knowledge of the literature of disease I have the highest regard, expresses in your issue of May 19th (p. 875) doubt as to the possibility of second attacks of true herpes. I think everyone will agree that in the vast majority of cases one attack of herpes does confer immunity. Yet I have seen at least three cases of recurrence of true herpes. The first was a surgeon whom I saw many years ago with an attack of herpes frontalis on the left side. There was distinct scarring. Twenty years later I saw the same surgeon suffering from an attack of frontal herpes on the right side, and, on my expressing surprise, he told me that some years before this attack, and after his previous attack of left frontal herpes, he had had an attack of herpes in the deltoid region, and he showed me the scarring which had resulted.

The second case was that of a lady whom I saw in consultation with the late Dr. Lewis, a case of severe herpes in the distribution of the right fifth nerve. A year before, Dr. Lewis told me, she had had an attack of herpes zoster, the scarring from which was still very marked.

The third case was a hospital patient who had an extensive eruption of herpes zoster. When I told him it was "shingles" he said that ten years before he had had an attack of shingles in the neck, and on examining his neck I found marked scarring of the nature of which I could have no doubt.

I may mention, incidentally, with reference to the third attack experienced by the surgeon that his daughter, a fortnight after the attack developed, became ill with chicken-pox.—I am, etc.,

London, W.1, May 21st.

JAMES TAYLOR.

### VACCINES IN THE TREATMENT OF GONORRHOEA.

SIR,—Dr. McCrea's article on the above subject in the *Journal* for May 5th (p. 755) deserves the careful attention of the venereologist, and for a variety of reasons, all of which have a very direct bearing upon the successful treatment of male gonorrhoea in the clinics working under the Ministry of Health scheme.

From my own experience when in charge of the venereal diseases clinic at Warrington, and in private practice, I can thoroughly endorse Dr. McCrea's general conclusion that the routine administration of vaccines in acute male anterior gonorrhoea not only reduces the number of complications, but materially shortens the time the patient is under treatment.

At the Warrington clinic from 1921 to 1924 vaccines were given as a routine, and during that period there was not a single in-patient admitted suffering from gonorrhoea or any of its complications. During this time the vaccines used were those of the residual type, prepared by Dr. C. E. Jenkins, the pathologist to Salford Royal Hospital. In the year 1924, when vaccines were not given as a routine, there were 119 in-patient days on account of gonorrhoeal complications.

Dr. McCrea's figures show; however, a surprisingly high incidence of posterior extension of the disease, both in the vaccine and the non-vaccine series—81 per cent. in the former and 88.5 per cent. in the latter. Under the routine treatment hereafter described the proportion of such cases approximates 25 per cent., and on investigation these are

found to have committed some indiscretion in treatment, exercise, or drink. A proportion of 80 per cent. is certainly not unusual where reliance is placed upon the patient treating himself with a syringe, and no vaccine is sufficiently potent to counteract the damage wrought by that most dangerous of all urological instruments.

The routine treatment I adopt for a case of acute anterior urethritis (duration two to seven days) is as follows:

(1) Alkaline diuretic mixture.

(2) Wearing of a proper suspensory bandage of the type made and provided at the City of Salford Municipal Clinic.

(3) Vaccines every seventh day for nine weeks.

(4) *Daily irrigations into the bladder from the commencement*, with the lowest pressure sufficient to overcome the resistance of the sphincter muscle. For the first three weeks the irrigations are of potassium permanganate, increasing in strength from 1 to 3 grains to the pint twice or thrice daily. In the next three weeks the solution used is oxyganide of mercury in similar strengths, given twice daily. In the seventh, eighth, and ninth weeks pieric acid is used, increasing in strength from 1 to 3 grains to the pint, and administered once a day. In the tenth week silver nitrate, 1 in 10,000, is used on alternate days, and during this week the urine and the prostatic secretion are examined. From the commencement of treatment, upon every occasion the patient attends, smears are taken if available, and the urine is examined at each visit. During the eleventh and twelfth weeks treatment is entirely suspended, the patient merely attending for urine examinations daily. In the thirteenth week there is given a prophylactic injection of vaccine or of nolan, and specimens are taken for examination in twenty-four and forty-eight hours.

Criteria of cure are: no discharge, no pus in morning urine, no gonococci recoverable from urethra or prostate, no abnormal prostatic smear, urethra normal on urethroscopic examination. Permission to marry is not given till the patient has been negative for six months after the cessation of treatment.

I have found that under this regime approximately 75 per cent. of acute gonorrhoeas remain anterior in site and are free from all clinical and bacteriological signs of the disease by the tenth week. In no such case has a relapse been observed in the six months succeeding the cessation of treatment. This is to be attributed to the following factors: (1) routine vaccines; (2) bladder irrigation from the beginning; (3) change of solution every week as to strength and every third week as to kind; (4) absolutely forbidding the patient to use a syringe; (5) irrigation at least once daily for the first four weeks; (6) if the patient is unable to attend at least once daily he is provided with a correctly designed home irrigator, in the use of which he is thoroughly and practically instructed.

In patients who appear with a discharge of two days' duration or less, a more intensive line of treatment is adopted. This consists of:

(1) Routine vaccines; (2) during the first week posterior irrigations with potassium permanganate (1 grain to the pint) thrice daily; (3) after each irrigation the patient lies on the couch and 20 minims of warm iodogol are injected into the anterior urethra, the penis clamped, and the iodogol gently massaged along the canal. This is retained for at least fifteen minutes. In 50 per cent. of such early cases there are no clinical or bacteriological signs of the disease at the end of five weeks. The iodogol is discontinued at the end of seven days and the ordinary routine is carried out for the remainder of the time, except that from the fourth week onward the patient only irrigates once on alternate days.

I am convinced that the syringe is the main cause of posterior involvement, and that in clinic treatment it should, as is the case in the Salford Municipal Clinic, be relegated to the museum. Treatment is available in this clinic for males and females every day from 8.30 a.m. to 8.30 p.m., and for four hours each on Saturday and Sunday. It would seem only possible to give the man with gonorrhoea adequate modern treatment in an establishment which is open twelve hours daily, and where the treatment is carried out by a whole-time staff of highly trained orderlies. Vaccines are decidedly worth while, but of much greater moment is the discarding of the syringe in favour of copious posterior irrigations from the beginning.

The method adopted in this clinic for the examination of pus in the second urine after prostatic massage is that described by Dr. Cuthbert Dukes in the *British Medical Journal* of March 10th (p. 391), any count over 100 being regarded as abnormal.—I am, etc.,

E. TYTLER BURKE,

Venereal Diseases Medical Officer for the City of Salford.

May 7th.

## THE ORIGIN OF ISCHAEMIC CONTRACTURE.

SIR,—Ischaemic contracture only occurs where tight bands have been applied round the injured part, never where the fragments have been merely replaced and kept at rest. In my view it is these tight bands which cause the trouble, and I never use them. To reduce the displacement and then fix "the arm up in full flexion by passing adhesive plaster round the doubled-up limb," as was done in the case described, is a thoroughly bad method, though Professor Hey Groves, in his article published in the *Journal* of May 12th (p. 807), characterizes it as "universally approved." It is this "universally approved" method which causes all the trouble. It should be entirely given up. Instead, after the displacement is reduced, either by manipulation or open operation, the wrist should be tied to the neck in Thomas's knotted sling, leaving the arm, elbow, and forearm free.—I am, etc.,

PAUL BERNARD ROTH,

Orthopaedic Surgeon, and with Charge of  
Fractures, Miller General Hospital.

London, W.1, May 14th.

## THE INTRAVENOUS INJECTION OF INDIGO-CARMINE.

SIR,—In the *British Medical Journal* of December 10th, 1927 (p. 1087), Mr. W. W. Galbraith is reported as employing, in the investigation of patients suffering from renal tumours, "an intravenous injection of 5 c.c. of a 4 per cent. solution of indigo-carmin."

Surely 4 per cent. is a mis-report for 0.4 per cent., since a 4 per cent. solution of indigo-carmin involves a contradiction in terms, indigo-carmin being soluble only up to 0.8 per cent. The mistake should not be allowed to pass without remark, for others might be tempted to adopt the stated technique; and, as this would have grave risks, I hope that I may be allowed to quote from a recent short article in the *Clinical Journal* (April 11th, 1928), in which I reported the only case which I have witnessed of the intravenous injection of 4 per cent. indigo-carmin.

The patient, "a woman of 41, who was being cystoscoped under general anaesthesia, suddenly became of green-yellow colour shortly after the intravenous injection of 2 c.c. of 4% indigo-carmin, and became collapsed." Various restorative measures were employed, and the patient slowly improved.

"On coming round from the anaesthetic she complained that she could not see, but this disquieting phenomenon fortunately disappeared within 24 hours."

"20 c.c., or less, of 4% indigo-carmin may be used for intramuscular injection in testing renal function, or in order to find the ureteric orifices, during cystoscopy; but the dye is more commonly and conveniently given intravenously as a 0.4% solution. It should not be intravenously administered in a preparation of much greater strength than this, as it is soluble only up to 0.8%. In greater concentration the dye is no longer in solution, but in suspension, and, although then suitable for intramuscular injection (since the muscular tissues filter off the particles), is unsuitable for direct injection into the blood-stream, as embolism may occur."

"Macalpine, speaking of indigo-carmin, says that 'shock, dizziness and pallor have been recorded as resulting from its use at too great strengths,' and cites two cases in which 'a 4% solution was used by mistake. In addition to some slight vomiting, the skin—especially around the eyes and over the scrotum—became a bright indigo blue. One of the patients also suffered from transitory convulsions, due doubtless to minute emboli of undissolved dye lodging in the cerebral capillaries.'"

"Although, as in the instance above quoted, recovery ensued, such cases emphasize the importance of noting the exact position of the decimal point before administering intravenous injections."

—I am, etc.,

ALEX. E. ROCHE, M.D., M.Ch., F.R.C.S.

London, W.1, May 10th.

\*\* The report was printed in the form in which it came to us from the Royal Medico-Chirurgical Society of Glasgow.

## MEDICINE, LAW, AND THE PUBLIC.

SIR,—Some time ago a judge of the High Court upbraided and lectured a medical witness who asked for his fee before he was sworn. The learned judge must have known that the witness was within his rights. The witness presumably thought himself justified in asking to be paid before giving evidence.

Quite recently a jury has gratuitously expressed the opinion that a defendant doctor should have called in another doctor to hear the plaintiff refuse the treatment advised. Surely this is impertinence in every sense of the word.

Now we have a coroner and his jury criticizing the methods of one of our greatest hospitals in that a resident medical officer, on his own responsibility, sanctioned the transfer of a patient to another institution. The coroner would pass, without criticism, similar action on the part of a practitioner outside the hospital, but in the case of the hospital he recommends that such a transfer be authorized by two resident officers acting in consultation and then sharing the responsibility.

These three incidents call for reflection. What is the meaning of it? It is true that many learned judges of to-day treat the medical profession as one to be respected and deserving of consideration. On the other hand, there are some highly placed members of the legal profession who resent the rise and progress of our profession. For centuries the law has had high places, large emoluments, and good social status among its attractions; while the profession of medicine has been in a lowly state. The progress of medicine has altered the relationship, and it is possible that the profession of law resents the change. Can it be what novelists and psychologists call the "inferiority complex"?

With regard to juries, we have to remember that they are composed of members of the public. The public, when in good health, are not in sympathy with doctors. Their conversation in railway carriages and other places is largely about ailments. Remedies are freely suggested, mostly unorthodox. Osteopaths, chiropractors, herbalists, Continental charlatans are all recommended as being so much better than our doctors at home. All classes drink patent medicines, advised by their friends or the chemist, for the cure of ailments that have not been diagnosed. These advisers would hesitate to recommend a particular motor car, on the ground that they did not understand enough about it. But the much more complicated mechanism of the human body does not daunt them. So many of the public have learnt to read and so few to think. There is the risk of an ignorant valetudinarian public expressing unjustified opinions from the jury box.

What is to be done about it? Very little can be done in court, and nothing can be done with the public. But the members of both professions who meet in friendly fashion to discuss matters of medico-legal interest might consider the matter. If a good example were set by the leaders of the legal profession it might permeate through all the courts, possibly even to the coroner's.—I am, etc.,

MEDICAL RESPONSIBILITY FOR LUNACY  
CERTIFICATION.

SIR,—There has been not a little anxiety lately in the minds of the medical profession regarding the risk of liability for the certification of alleged lunatics.

This risk would be avoided if the procedure were so altered that the doctor was not obliged to take upon himself the invidious position of being the agent to declare that so-and-so is a fit and proper person to be shut up in an asylum and deprived thereby of all civil and personal rights. The doctor's true function is not to imprison people, but to give advice as to the treatment most conducive to recovery.

As matters now stand, the doctor, when called in, has in most instances to depend on hearsay evidence from those in touch with the individual who is said to be affected. He has often but little opportunity of discovering for himself what amount of truth there is in the assertions made. Not being himself a witness of what has occurred, he may have extreme difficulty in drawing up a certificate based on personal observation.

In the memorandum presented by the British Medical Association to the Royal Commission on Lunacy all cases of mental instability are divided into two classes: (1) those for whom detention is a necessity; and (2) those for whom

it is not; the criterion for certification being that the individual can be proved to have so conducted himself as to render detention a necessity.

It is evident that the parties who can themselves give first-hand proof as to the conduct they have witnessed are the proper people to appear before the magistrate, and to state what they know. The magistrate can then weigh the evidence, thus carrying out the true function of a judicial authority, while the doctor is at the same time secured from liability.

The individual concerned should, in fairness, be represented by a friend; but there need be no publicity in the matter.—I am, etc.,

London, May 12th.

#### THE HARVEY CHAPEL AT HEMPSTEAD.

SIR,—May I add a note to my late friend Sir Dawson Williams's article on William Harvey? He stated that lapping in lead seemed to be peculiar to the Harvey family. It was common to all the better class from Henry VII to about 1675. Henry VII, his wife, and James I are all in shaped lead coffins in the vault in Westminster Abbey; Sir Henry Vane is in a very much more elaborate one in Shipbourne Church, near Tonbridge. I have seen one for a child so shaped that it would stand on its feet. The case was made by casting in two halves. After having been banded and sometimes embalmed, the corpse was laid in the lower half, and the body-shaped top was then soldered to this, and as a rule, a lead or silver inscription plate was soldered to the breast. The inscription on Harvey should read:

DOCTOR  
WILLIAM + HARVEY  
DECEASED + THE + 3  
OF + JUNE + 1657  
AGED 79 YEARS.

The bound volume of the 1767 edition of his works was encased in lead, and the hermetically sealed bottle containing the engrossed parchment account of the day's proceedings in another lead case. Both were placed at the foot of Harvey's coffin in the sarcophagus. These details are from the privately printed account (1883) of this second funeral of Harvey by the late Dr. William Munk, librarian to the Royal College of Physicians.—I am, etc.,

#### PHARYNGO-OESOPHAGEAL SPHINCTER.

SIR,—I have often deplored the fact that British discoveries frequently remain unrecognized and unappreciated until they are re-imported under a foreign name. Mr. Negus's letter (p. 879) seems to me to add one more to the list.

Although the discovery of this muscle has been attributed to Killian, Jackson, and others, it is, I believe, the fact that it was first described long years ago by Sir Everard Home, one of John Hunter's illustrious successors, and his beautiful dissection of it can still, I think, be seen in the Royal College of Surgeons Museum.

It is true to say that with the advent of oesophagoscopy its clinical importance has been pointed out by Chevalier Jackson, but although I yield to none in my admiration for Dr. Jackson and his work, I think that the credit for its actual discovery must remain with Sir Everard Home.—I am, etc.,

London, W.1, May 18th.

WALTER HOWARTH.

#### CAUSES OF THE DECLINE IN TUBERCULOSIS MORTALITY.

SIR,—Often in the last seventeen years the *British Medical Journal* has published for me views in direct conflict with what Sir Robert Philip enounced at Bath on April 20th.\* I have urged that as against phthisis (bovine tuberculosis is another question) the statesman's supreme weapon is the enhancement of the standard of living of the poor—in two words, of real wages. Sir Robert so far

appears to agree; where we part company is that I argue that history here and elsewhere tendencies that the best, perhaps the only, way of raising real wages is by the policy known as *laissez faire*. There are gaps in Sir Robert's argument that seem wholly to invalidate it. May I hope that he will resolve my doubts?

1. He begins from 1871; why not from 1841? There is nothing in history to equal (though there are a score of instances of minor degree corroborative) the fall of the phthisis mortality which followed Peel's daring reform of the tariff from 1842 onwards. As Koch has said, that fall was greater before the cause was known or anything public done than since. By 1880 the mortality had fallen by more than 50 per cent.; if the decrease had really been accelerated the disease would have been extinct by now. Sir Robert thus omits to quote the most brilliant success known, and that due to a distinctively *laissez faire* policy, in its proper, as well as its vulgar, sense.

2. He omits to mention the slackening of the rate of decline in this century. The rate had become practically stationary when Professor Karl Pearson was able to prophesy a rise in 1915. So, in 1912, did I. Professor Pearson tells me that the interruption of the war was fatal to his data; to mine it was an immense reinforcement. The crude death rate in 1917 was nearly double—in 1918 more than double—that of 1905.

3. He pointedly leaves out the war figures. I submit that you can find in them the solution of the problem. The tables of all countries which keep records show that an economic change—that is, of real wage rate—registers itself on the phthisis curve in the third year. Thus the long, slow fall of real wages from 1896 to 1910 shows itself in the gradual slackening of the decline of mortality; the rapid fall from 1912 to 1914 in the rise from 1915 to 1917. If the theory were correct, a fall should begin in 1918. It did, as the Registrar-General points out. As if to clinch the point, the rate for the year was raised above 1917 by the influenza outbreak of 1918; but the excess was due to deaths in asylums, and the disease had picked out people uninfluenced by wage fluctuations, as small-pox picks out the unvaccinated in a school. The quinquennium is the only one in our records which fails to show a decrease on its predecessor; the increase is the biggest we have known, and follows as the prophesied effect, or at least *si fallor*—the sequel of the biggest effort the State has made.

4. He bases the triumph of State activity on the rates of 1919-24, and does not explain why the great and sudden improvement had taken place. But the State was no more active in 1919 than in 1913, perhaps less so. In wages, however, there had been a startling difference ever since 1915.

We who advocate a drastic curtailment of State activities do so because we know from history that State gifts to the poor are always at the expense of real wages and always tend to demoralize. If this needed proving, the course of events this century should have made us wary. Only the other day the House of Commons took it for granted that the Insurance Act had resulted in wide demoralization—the only difference of opinion was as to whether it was among doctors or patients—in the year of lowest mortality with the highest morbidity.

I submit that, when all the factors are considered, the question is whether State intervention, so far from diminishing phthisis, has not retarded the efforts of a greatly advanced science and the results of a vast improvement in social habits and conventions, which together might by now, of themselves, have extinguished the disease.—I am, etc.,

Bath, May 2nd.
